S.P.E.E. Joins A.S.M.E. at Annual Meeting to Consider Engineering Education

A Group of Papers Presented at the A.S.M.E. Annual Meeting, in Which are Presented the Particular Needs of the Industries and the Problems that Confront the Engineering Faculties

ONE of the outstanding features of the 1921 Annual Meeting of The American Society of Mechanical Engineers was the joint session held on December 8 with the Society for the Promotion of Engineering Education, and devoted to a consideration of professional engineering education for the industries. Four papers were presented at this session, over which Prof. C. F. Scott, president of the S. P. E. E., presided, namely: Professional Engineering Education for the Industries, by F. C. Pratt; A National Policy on Engineering Education, by A. G. Christie; College Education as Related to Industry, by J. E. Otterson; and The Engineering School and the Industries, by Dexter S. Kimball, which latter partook of the nature of an introduction to the discussion of the preceding papers. The texts of these papers follow, together with a brief abstract of the discussions which they brought forth.

The session was opened by Professor Scott who presided: he said in part:

The industries constitute the organization through which engineering utilizes the forces and materials of nature and organizes and directs human activities for the benefit of man.

Today the national society of engineering and industry meets with the association of engineering educators; this is a conference between users and producers of human material for leadership in industry.

If producers and users of steel rails were in conference they would discuss the uses which rails are to serve, classifying the kinds of service, considering wherein past products had failed, inquiring as to chemical analysis and metallurgical treatment. They would seek improvement in production and discrimination in use. But the more difficult problem of the human material for technical and administrative leadership has received less attention.

It is easier to analyze steel than students; physical tests are definite—psychological tests are still indefinite; it is easier to specify materials than men; steel is inert and passive—men are alert and erratic.

But when, if ever, have these leading societies in engineering industry and engineering education met together for conference? Each society has been engrossed in its own activities for thirty or forty years. Now they are finding something in common. Users and producers are in conference. Let us try to agree on what we want and then determine how to get it and how to use it. How may boys of differing kinds be individually developed and fitted to varying needs and opportunities?

First, as to the schools. What are they teaching? The distribution of subjects in the four year courses (not including summer work) in mechanical engineering and administrative engineering at Yale is given in the following tabulation:

		Per cent	
		Mechanical	Administrative
General	History and English	13	13
Science	Chemistry, Physics and Mathematics	31	24
Engineering	Drawing, Materials, Mechanics, Power, Electrical Engineering	46	28
Administrative	Economics, Accounting, Management, etc.	8	21
Elective	Engineering, Administrative, etc.	2	14

Second, returning to industry. What is the quality basis of selection of graduates for an industry? Does industry want men familiar with current practice, or men grounded in general principles ready to acquire practical experience rapidly? Industry certainly does not expect any graduate to fill any position irrespective of natural ability, aptitude and preference, but what is the present practice in determining the qualities of the raw material and of adapting it to the needs?

If some men are needed for research and invention and a larger group for general engineering and production and sales and another for executive and administrative functions, are men for each kind of work carefully selected and specially trained? The inventor, the originator is rare. A dozen or a hundred men for general activities are easier found than a single expert or originator. Has not much of the dissatisfaction of the past product of the schools been due to a misunderstanding on the part of industry as to what the college graduate really is and inability to train him in industry and utilize him efficiently?

The technical school has been trying to bridge the old time gap between the formally classical and the rigidly scientific. In forty years it has made a marvelous advance. The goal of its early aims was to produce engineers of materials and forces. But there is a new demand for an engineering type of mind for the organization and direction of men. Can the same raw material and the same educational machinery and methods produce both products? What changes will meet the new situation? Are they simple or radical? These are the things we are here to discuss.

Professional Engineering Education for the Industries

By FRANCIS C. PRATT,[1] SCHENECTADY, N. Y.

DURING the year 1920 the General Electric Company, with which I have the honor to be associated, took into its employ 400 college graduates, of which number—

340 were graduates of electrical engineering courses
20 were graduates of mechanical engineering courses
30 were graduates of business or administrative courses
10 were graduates of miscellaneous courses.

Practically all of the electrical and mechanical engineering graduates entered into the student engineering courses covering a one-year period which have been most carefully planned at the several works of the company, while the graduates of the business or administrative courses became members of its accounting department, taking a two-year course in business administration, higher accountancy and commercial law. Fifteen graduates, including two who had specialized in physics and nine in chemistry, entered the research laboratories of the company.

The records indicate that over a term of years about one-half of the young men entering the student courses remain permanently in the employ of the company in the engineering, manufacturing, commercial or administrative departments of its general and district offices, or of its works.

---

[1] Vice-President, General Electric Company.

In entering into the daily work of a great industrial organization these young men come into contact with actual manufacturing and business conditions and acquire self-confidence and a practical experience which, in my opinion, the colleges cannot and should not seriously attempt to impart.

I regard it as an exceedingly healthy sign that there are so many inquiries being made as to our methods of technical education, but, at the same time, I want to say that the young men who, during the past few years, have entered the employ of the company with which I am associated, have, on the average, been better prepared mentally, physically, and morally than ever before. This is a very broad statement, but a most careful study of the conditions and the many inquiries made of our leading men who have the opportunity to come in close contact with these young men justify this conclusion.

During the past two years we have been engaged in reorganizing one of our most important designing engineering departments, largely increasing the scope of its work and its personnel. In recently looking over a report of the organization submitted by the engineer in charge, I was struck by the references to two young engineers, each of whom had been out of the company's student engineering course for a period of less than a full year. The report referred to one of these young men as proving to be a resourceful and inventive experimental genius along his particular line of work, and to the other as having perhaps the clearest understanding of the mathematics of this particular line of any one in the employ of the company.

The line of work is an exceedingly broad one, the engineer in charge is a particularly discerning man, and I think it a matter of great encouragement that talent of such character is being turned over to the industries by the educational institutions. It is true that the report, in referring to these two young engineers, referred likewise to four somewhat older and more experienced men who were reported as also doing particularly notable work in the department.

Increasing Demand for Trained Engineers

I have recently seen a statement that statistics show there has been a constant decrease in the number of engineers graduated from our American universities. The statistics were not cited in connection with this statement, but if, perchance, this statement holds true, the tendency would seem to be an unfortunate one, in view of the larger demand for engineering activities in our modern life, as partly reflected in the following statistics taken from the official records of Yale University:

Increase in all Yale graduates for years 1904 to 1916:

Law, medicine, ministry and teaching, combined	24 per cent
Manufacturing, finance and mercantile pursuits, combined	83 per cent
Engineering	160 per cent

I have also seen suggestions that the number of so-called cultural studies should be decreased and greater specialization made in the essential subjects of science, mathematics, the native language, and of commercial application of what is learned, and that the colleges should turn out young engineers whose services are of immediate value to the employer without several years of practical experience being necessary.

I have little sympathy with such points of view for many reasons, among which are the following:

While familiarity with apparatus obtained from laboratory work coincident with undergraduate studies is of great value in giving the students more appreciative knowledge of their subjects, as are also frequent visits to, and summer work in, industrial establishments during the undergraduate period, yet I am confident that nothing which the colleges can give can take the place of the practical experience gained in the atmosphere of an industrial organization, bringing with it an intimate knowledge of both methods and men with which and with whom one's life work is to be associated. In my opinion the time in college is so valuable that it should be primarily devoted to those things which can only be acquired later with a great deal of difficulty, the fundamentals necessary to all advanced study.

Earnest efforts are being made to combine the advantages of instruction in theory with those of practical experience by coöperative courses, carried on jointly by educational institutions and industries. A final opinion in regard to the effectiveness of these courses must, it seems to me, be held in suspense awaiting more extended experience with them.

Too Early Specialization Results in Disproportionate Number of Mediocre Ability

My observations also lead me to the conclusion that the percentage of those who fail to attain a reasonable degree of success is greater in the group of men of mediocre ability but narrowly specialized education than in almost any other group coming within my knowledge. Such men, unless extraordinary vigilance is exercised by those in charge, become permanently attached to an organization doing specialized work for which they have no particular adaptability, clogging the opportunities for younger, more able and progressive men to advance. It would have been far better for such a man if the head of department had, at the end of one or two years of employment, recognized the circumstances and frankly informed him that he was not likely to make a success in the professional work which he had undertaken, and advised him to enter into some other vocation.

If I were to make a broad criticism of our methods of engineering education as it exists today, I should base it upon too early specialization of the student, resulting in the turning out of a disproportionate number of men of the class to which I have just referred, i.e., those of mediocre ability and narrowly specialized education.

I should be disposed to strongly criticise another condition in our colleges which I recognize as an exceedingly difficult one to overcome, and that is, as the result of the high degree of standardization, induced perhaps by the numbers who have to be taught, the more brilliant men in the class are retarded in their progress by the requirement of a standard which can be met by the less capable students. If we are not only to attain, but also maintain, great eminence in the engineering professions in America, we should, and I think must, devise some means whereby the more promising students can with greater facility advance with breadth and thoroughness in their work.

It is, I think, significant that in the organization with which I am in daily contact, a noticeable number of our most accomplished theoretical engineers and research laboratorians have either pursued post-graduate studies at European universities, or else have had all of their scholastic training abroad. This may suggest an opportunity for American educational institutions which is not fully met at the present time. In this connection I think that the colleges should sternly resist the temptation to enter into specialized fields which are adequately covered by kindred institutions, and that better results would follow if, in general, each endeavored to maintain the strongest possible staff of teachers to give most thorough instruction in the fundamentals of the sciences, engineering, economics and languages, and confine its specialization to such work as it is preëminently fitted to carry out.

The industries need administrative men well versed in the sciences and in engineering, in order that they may lend appreciative and sympathetic support to the technical developments, which are, in fact, the very life blood of the industry and on which its future primarily depends. That the colleges of the country are alive to this need, is evidenced by the number of courses which have in recent years been established, teaching the fundamentals of the sciences, engineering, economics and languages, and variously referred to under the names of administrative engineering, commercial engineering, or other courses.

While it seems to me probable that a much larger proportion of the graduates of such general engineering courses will be utilized by the smaller manufacturers rather than by such highly specialized organizations as pertain to the electrical industry, yet I want at this point to put in a strong plea for the more thorough appreciation and use of technical graduates by all industries, both large and small. It is, of course, apparent that a college education is not in any sense the only road to industrial accomplishment, and, in fact, some of the ablest engineers and administrators of my acquaintance have secured the fundamental knowledge upon which their life's work has been based while persistently working in practical fields and without having the foundation of a college education. One frequently finds, however, in such cases, that the individual's development had been profoundly influenced by close association in his

work with a master mind, who, in reality, became a great teacher to him.

Need of the Industries for Strong Designing Engineers

The industries need strong designing engineers thoroughly versed in the theory and practice of the art, who have such knowledge of material values and of men as to render their work effective. In general, the industries must look to the colleges for young men who have the knowledge, the enthusiasm for constructive work and the patient tenacity, which alone go to make up a successful designing engineer. In many respects the loss of a good designing engineer to an industry leaves a vacancy which is harder to fill than almost any other, as preëminence in design can only be attained through a happy combination of natural ability and of knowledge and experience gained by years of intelligent and exacting work. Owing to the highly developed state of the art there is undoubtedly a great deal of routine work to be done in designing engineering, which is not inspiring to young men, and experience indicates that a diminishing proportion of technical graduates is drawn toward this most important branch of work. While this must, I think, necessarily be one of the problems for the colleges, it is also one of very immediate concern to the industries, demanding the most resourceful consideration. In general, the goal of success in design work seems more remote to the young graduate than in other branches, and also the character of the work more exacting and confining. On the other hand, this fascinating field of investigation, research, and constructive accomplishment should appeal most strongly to one who has the imagination and courage to look well into the future, and the stamina necessary to accomplish a difficult task. I feel certain that far too many capable young graduates sacrifice their greatest ultimate development by yielding to the temptations of early rapid advancement along the easier lines, without sufficient thought of the future.

I wish only to add one thing more, and that is to point out the wonderful opportunities which modern industry offers in its research laboratories to specially talented and most highly educated technical graduates. The colleges must, I am sure, be most liberal in providing instruction and laboratory facilities for the growth of such picked students, and in inspiring them by the work and example of a few really great teachers.

Summary

1 A careful study of a large number of college graduates employed at the several works of the General Electric Company indicates that our educational institutions are developing young men of real ability for the industry.

2 The suggestion that is sometimes made to reduce the amount of cultural studies in order to more intensively specialize on technical subjects, is not viewed with favor.

3 The time in college is of such value that it should be primarily devoted to those things which can only be acquired later with great difficulty. At best, the student cannot hope to attain in college the well-rounded knowledge and practical experience that are to be gained in an industrial organization.

4 A broad criticism of methods of engineering education is that it undertakes too early specialization of the student. Another is the lack of facility offered to the more capable students to rapidly advance.

5 Suggestions for modification and improvement of American educational methods may be gleaned from the fact that a noticeably large number of accomplished theoretical engineers and research laboratorians have either received all their education or pursued post-graduate courses at European universities.

Best results may be expected if each educational institution will strive to maintain a highly capable staff of teachers in the fundamentals of the sciences, engineering, economics and languages, and restrict specialization to only that work for which it may be preeminently qualified.

6 The teacher in engineering courses should constantly emphasize to those students who show special aptitude the great need among the industries for able designing engineers.

7 Through its research laboratories modern industry offers to specially talented and highly educated technical graduates wonderful opportunities for development.

A National Policy on Engineering Education

By A. G. Christie,[1] Baltimore, Md.

In one of the recent Aldred Lectures, Mr. Arthur West said among other things: "It is to my mind one of the greatest functions of the technical school to seek out from among its students those who have a natural aptitude for the profession and to help these men to the utmost if in addition to their technical abilities they show the character necessary to make such help worth while. I counsel the careful and painstaking education of the best students even at the expense of the mediocrities that exist in all student bodies. It should not be the duty of the faculty to nurse along the 'dubs' of the class to a precarious graduation. What modern civilization needs is not more engineers but better ones."

Dean F. L. Bishop is reported to have stated at a meeting in New York last spring that there is no first-class engineering school to be found in America. Dr. Comfort A. Adams supported this statement and guaranteed that he could prove in a five-minute oral examination that 98 to 99 per cent of the graduates in electrical engineering from any institution in the country did not understand in a thorough fashion the fundamentals of the subject.

One is led to conclude from the above remarks that the engineering world desires only first-class men, but that the engineering colleges of this country are unable to furnish such men. Since the late war this country has been the world's leading nation. If the United States would continue to hold this foremost position it must become a leader in the arts and manufactures, in culture and education, and particularly in engineering education, for our modern civilization depends to such a great extent upon the work of engineers. If it is true that we have no first-class engineering schools, it is time that earnest inquiry should be made to determine wherein we are lacking and what remedies should be immediately applied. This is a national matter, for national leadership in manufacture and commerce depends on engineering achievements. A national policy on engineering education is therefore a pressing need at the present moment.

Work in Foreign Colleges Generally of More Advanced Character

When discussing the requirements of a first-class engineering college, it is instructive to consider the leading engineering colleges abroad. Before the war some of the German technical schools were regarded very highly. Those at Charlottenburg, Dresden and Munich shared with the Zurich Polytechnic of Switzerland the reputation of being in the first class of continental engineering institutions. Foreign students, including Americans, were attracted to these schools in large numbers and this further increased their reputation. These colleges had first-class men on their staffs and in general instruction was of a high order. Particular emphasis was laid on fundamentals of engineering and on research. The German states were liberal in their financial support of such institutions and the professors were comparatively well paid and enjoyed a high social standing. These professors did a relatively small amount of teaching and devoted their time principally to research and to the leisurely study of their specialty, on which they generally wrote extensively.

Much of the actual experimental work in research in these foreign schools was done by graduate students and by paid assistants, of which latter there were sufficient numbers to readily carry on the work. The instructional staff did little clerical work and practically no student advisory work, as we know it in America. Therein lay the weakness of the German system. Great care was taken to impart exact technical and scientific knowledge to the students, but little thought was given to the development of char-

---

[1] Professor of Mechanical Engineering, Johns Hopkins University. Mem. Am.Soc.M.E.

acter and personality. A recent speaker commenting on this fact stated that British and American engineers are frequently placed in executive charge of large enterprises, while continentally trained engineers are employed by them to do the designing and computing, character, resourcefulness and ability to handle men governing the selection.

A factor that has considerable influence on the courses offered in any technical college is the character and degree of advancement of the work done in the preparatory schools. In this particular the continental technical schools are particularly favored, for in general more advanced mathematics and physics, together with more cultural subjects, are taught in their preparatory schools than in American high schools. In fact, the equivalent of the first year's work and often a portion of the second year's work in American engineering colleges is required for entrance to the continental technical school. Consequently the work in these foreign colleges is in general of a more advanced character than here. Furthermore the students are older and more mature at entrance to such continental colleges.

An attempt is being made in Great Britain to build up a first-class engineering school at the Imperial Technical Institute, London. The war, however, prevented full development of these plans as soon as was hoped might be possible.

Conditions in American Colleges

Let us now consider conditions in American engineering colleges. These vary from small, ill-equipped schools to institutions that should be considered among the world's best, both in equipment, ability of staff, and character of instruction. There still appears to be room for all these colleges, even though the character of training varies over a wide range. This is due to the fact that the technically trained man has many fields open to him after leaving college. The demand for men to fill subordinate positions in the industries will always take care of the less able men and those whose training has been inadequate. The more highly trained and more capable men advance to the foremost places in the profession, which generally lead to executive positions of a business character. An increasingly large number of engineering graduates have business and not technical positions as their sole objective. They take the engineering courses in college largely because they believe that the thorough analytical methods taught there and the training in the ability to "think straight" will be a considerable asset in business life. Engineering students may therefore be divided into three general classes: (1) Those of a truly scientific turn of mind who are capable of grasping and developing theories and of applying these to the analysis of engineering problems; (2) men of a practical nature, less capable or insufficiently trained to fall in the first class, yet very necessary for the subordinate positions in industry; and (3) those whose objective is pure business life. The great majority of students fall in the last two classes and this influences the character of college instruction to a marked degree. Practical laboratory and shop courses are stressed in many colleges and there is a steady demand for more and more instruction on the principles of organization and business economics.

The increasing popularity of the engineering courses has led to steadily increasing enrollments in nearly all colleges. Instructional staffs are overworked and underpaid. To care for this influx there seems to be a tendency to organize certain colleges on what would be called in factory organization a "quantity production" basis. Large numbers of students are handled according to definite fixed plans and personal contact is largely lost between instructor and student. A most unfortunate condition exists when an able and inspiring teacher is promoted to the head of a department and becomes so loaded down with administrative details that he does little or no teaching and loses the opportunity to exert his personal influence on students who should normally receive his instruction. The "quantity production" idea gives little or no opportunity for character building, which after all is the true basis for success in after life. Where students are handled in quantity the men automatically recite, work up laboratory reports, and pass examinations with very little opportunity for independent thought or action along technical lines.

Engineers in practice frequently criticize the engineering colleges very harshly for turning out graduates with seemingly inadequate training. Usually these critics have lost their proper perspective or have forgotten just how little they themselves knew of their specialty when they entered college and when they were graduated. They fail to fully appreciate the character of the boy as he enters college and with whom the teaching staff has to deal.

It has already been pointed out that the average student entering American engineering colleges is younger and less thoroughly prepared in fundamentals than the continental student. The American boy has several things in mind when he enters an engineering college: First and foremost, that the training will enable him to earn a better living than if he were without training and therefore he favors practical courses to pure theory; second, that athletics, fraternity life, and other college activities are almost if not actually of equal importance with instructional courses; and third, that his four years in college before entering a cold-blooded business world are going to be the happiest in his life and he must not fail to have a good time during his college career.

What Engineers Demand of the Graduate

Such in general are the motives and ideals of the undergraduate of the technical college. What do engineers demand of the graduate? In the opening paragraph Mr. Arthur West calls for better engineers by a process of selective education of only the most promising men. In what way must he be a better engineer? In the Report of the Carnegie Foundation for Engineering Education by C. R. Mann, it is pointed out that practising engineers stated the desirable qualities of an engineering graduate in the order of their importance as character, judgment, efficiency, understanding of men, knowledge and technique. Particular attention should be directed to the fact that technique, in which the continental graduate excels, is placed at the bottom of the list, while character holds first place. A recent survey by C. E. Magnusson[1] indicates that character is still considered of first importance but should be combined with a truly professional idea of service, and also that thorough training in fundamentals is more necessary than specialization.

Character building, tact, initiative, thoroughness, etc., can be developed best in the undergraduate by intimate contact with high-grade instructors, and by participation in college activities and athletics under more or less faculty supervision. This may be achieved in the smaller colleges, but unfortunately only a few have adequate laboratory equipment and can afford to secure the best men for their staff. "Quantity production" in larger colleges must be replaced by smaller groups of students and larger, less hard-worked, and better-paid staffs if the best results are to be secured. The adoption of a common code of ethics by all national engineering societies and the requirement that every graduate in engineering affirm this code would greatly increase the graduate's sense of responsibility to his profession and would certainly tend to elevate its ethical standards. Thoroughness and accuracy can be developed by problem work, and particularly by recitation courses. Personal contact of students with faculty is probably most highly developed under our American student advisory systems.

A limited student body has been characteristic of certain of our best medical schools. The Engineering Department of Johns Hopkins University since the war has deliberately attempted not only to elevate the standards of instruction, but to limit attendance among the upperclassmen to a small number of men. An attempt is thus made to retain the better men only of the first two years. This permits the most efficient use of facilities without overcrowding, and retains close personal contact between student and instructor. Furthermore, greater emphasis is laid on fundamental theory than on informational and special applied courses, leaving the latter for advanced study.

When due consideration is given to the age at entrance and to the preparatory training of our freshmen, it is obvious that one cannot expect a finished engineer at the end of a four years' course. The criticisms of the undergraduate work of our colleges by Dean Bishop and Doctor Adams seem therefore unfair.

Students in law and medicine are generally required to have a collegiate degree before taking up professional work. Such a requirement would unquestionably produce a better class of graduates if applied also to the engineering colleges. The profession as a

---

[1] *Journal A.I.E.E.*, September, 1921.

whole, and particularly employers of engineers, have, however, offered no special inducement to the colleges to develop such men. In fact, with the large number of graduates of the second and third classes mentioned above, it is doubtful whether the time and expense of such training can be justified or is needed.

Graduate Work Should be Concentrated in Certain Selective Colleges Given Strong Financial Support

What about the highly trained engineer and the research engineer comprising the first class? This is the class of men on whom America must depend for future leadership in engineering. These men form a relatively small proportion of the graduating classes. Their training, however, should be of broad character during the early part of their courses, though in regular undergraduate courses this selective education is seldom possible, and later they should be further developed along certain specialized lines. Such men would undoubtedly benefit by collegiate courses before taking up engineering training. It is not possible however, to select from a group of applicants for admission to college the men who will later develop into the best engineers, and who are worthy of the most extensive training. Some plan must therefore be developed which will permit these specially gifted men to be given advanced training and to carry out research work. Many colleges have neither the money, facilities nor staff to offer adequate graduate work in all branches of engineering. It would therefore seem best to concentrate our graduate work in certain selected colleges which should receive the strong financial support of the industries and of the Government and the moral support of the profession at large. If scholarships to these graduate schools could be provided for the best undergraduates from all engineering colleges, well-developed technical men would be available to the industries who would equal if not surpass the continentally trained men. The requirements for admission at such graduate schools should be very rigid so that only the best men with adequate preparation could enter.

If the industries demand highly trained men from the colleges, they must be prepared to make such training worth while. When a request is made to an engineering school for a man, if a degree of Master of Engineering or Doctor of Engineering is demanded and if such men are given preference for positions and are paid somewhat higher salaries than the ordinary graduate, students will soon desire to get the advanced training. Graduate students in engineering will be few and of mediocre character as a rule until such an attitude prevails on the part of employers.

The new national policy on engineering education therefore requires greater financial support for the colleges, so that an adequate staff of high-grade men may be employed and personal contact with students secured through small classes. Greater emphasis must be given in instruction during the four-year undergraduate period to fundamental courses, leaving special professional training to graduate years. Certain colleges should be designated as graduate schools and adequate provision made for their proper support both by Government agencies, by private endowment, and by the industries. Scholarships should be provided by the state, by industries, or by the profession which will enable eligible undergraduates from all colleges to continue their work in the graduate schools. Finally, employers who desire highly trained technical and research engineers must give first consideration to the men with graduate degrees and must be prepared to reward them financially in proportion to their extra effort and greater expense in educating themselves.

The burden of maintaining America's supremacy in industry and commerce rests largely on the engineer. Let us therefore as engineers place before the American people this new national policy on engineering education so that our young men entering the profession may be the best fitted in the world to carry this burden and to advance still further the art and science of engineering.

Engineering Education as Viewed by the Industrialist

By J. E. OTTERSON,[1] NEW HAVEN, CONN.

THE pedagogue is interested primarily in the process of education. The industrialist is interested primarily in its product. The student upon graduation, must pass from the supervision of the pedagogue to the critical survey of the industrialist.

It seems fair to assume that the purpose of education is something more than the mere acquisition of knowledge. The industrialist is obliged to look for something more. The student is likely to find upon graduation that those things which he has regarded as the purposes of the educational processes through which he has passed, now become only a means for the accomplishment of the real purposes of life. It is in developing this change of viewpoint that the student is likely to meet with disappointment, perhaps discouragement, and during this period the industrialist finds difficulty in adapting the student to his utilitarian purpose.

Knowledge is not of itself a qualification for large responsibility in industry. The encyclopedic type of mind which merely records impressions and facts brought before it may lack those qualities of imagination and initiative so essential to the accomplishment of practical things under adverse conditions, which do not always evidence strict conformity to the laws governing recognized and recorded knowledge. Something more is required than that type of mind which is merely a reservoir containing a large amount of knowledge in a static state. Modern industry is dynamic and moves at a tremendous pace. We want, therefore, the type of mind that will be immediately energized when the current is turned on; the motor type rather than the storage-battery, and when the individual progresses to larger responsibility he may be called upon to animate, magnetize and electrify other minds about him, and to develop the qualities of generation as well as those of motivity.

There are doubtless certain occupations in life where the possession of accumulated knowledge is both desirable and essential, but in industry this quality alone will not carry the applicant beyond the lower orders of subordination. He will take his place among those student clerical types that are the handbooks of industry; much thumbed and used and frequently showing signs of wear and tear and dilapidation; referred to for statement of facts or formulation of laws but in the emergencies of everyday life frequently passed by in the race for accomplishment. Such are not the positions in industry that are difficult to fill. The encyclopedic type is sufficiently common to meet the need and in the search for the type with initiative, vision, imagination and dynamic force, the industrialist must apply other methods than those of the school-room examination. The industrialist is concerned more with the effect of the educational processes upon the habits and character of the applicant than he is with the degree of learning which he has attained. The industrialist is interested in mental, physical and moral character rather than in pure intellectualism; more in the ability to acquire knowledge quickly through application and concentration than in the immediate possession of knowledge.

The habits of industry should have as their foundation the habits of the student who is preparing for industrial work. In passing from student life to industrial life he should be able to do so successfully by continuation of the habits he has acquired in his college training rather than by a radical change that places him in an unfamiliar environment of work and activity.

His college life should be something more than a mere signal drill. He needs the scrimmage and the actual game to develop his full qualities.

Some very practical industrialists hold the view that a college education is a handicap to business or industrial success and they point to the fact that something like 75 per cent of the responsible positions in industry are occupied by men who have not had the benefits of a college education but who have gone through the school of hard knocks; whose qualities are those of character, force, will power, initiative, industry, common sense and human

---

[1] President, Winchester Repeating Arms Co. Mem. Am.Soc.M.E.

understanding. It is indeed questionable whether within the limits of the training and experience of a college education these qualities can be developed with the same intensity and firmness as in the school of life that so closely links accomplishment with survival.

The college education most obviously and surely develops a larger capacity for social and cultured life but the social and cultural taste growing out of a higher education may prove distracting in a competitive field where complete concentration of a very practical kind is essential to success.

Without endeavoring at this point to place the responsibility, the college graduate who is an applicant for an industrial position all too frequently shows no knowledge of the work to be done in the field which he is about to enter. He evidences no particular desire, ambition or purpose and he has little knowledge of the direction in which he is going or desires to go. If an opening is offered him, he has no capacity of judgment as to his adaptability. He is generally quite willing to leave the question of his future work in life to the hurried determination of the industrialist, who in a ten-minute interview may attempt to analyze his character and assign him to a task in which all parties concerned hope that he may be successful. Obviously this is an uncertain and unscientific method of directing the human forces set free by college education.

Small wonder that so many find themselves in uncongenial employment, ending in discontent, perhaps discouragement, changing from one class of work and finally from one job to another without direction or control.

A force is defined by its magnitude and direction. I am not complaining as to the magnitude of this tremendous human force launched into the world with each graduating class, but I do regret the wasted energy that results from its lack of direction. Whose responsibility is it then to give it direction? Who is to sight the gun? Who is to lay it upon the target? Some such directing hand is necessary if we are not to be content with mere intellectual fireworks.

Development of Personal Talents

It is of course a question as to how far the college is expected to go in fitting men to take their places in a particular line of industry. In the ordinary four-year college course it is fair to assume that the college can do little more than lay the foundation for subsequent intensive training and development for a particular work. I am very definitely opposed to the shaping of educational processes toward training for a specialized type of work before there has been laid a foundation of general knowledge and comprehension. The specialization should come after a certain degree of intellectual maturity has been reached. I do feel, however, that at the same time the mind is being molded and stored with knowledge, an effort should be made to determine the talents and characteristics that must be the controlling factor in the student's later life, and an opportunity given for the development of those qualities that will ultimately express the real character of the individual.

Our college tests and examinations are primarily directed toward the determination of mental attainments as measured by the extent of acquired knowledge. I am making a plea for the development of tests of a different character calculated to determine the student's potentiality rather than his static state. These tests would be in the nature of or the basis of a psychoanalysis of the student's character through observation of his manner, personality, physiognomy, heredity, environment and college career. These should be matters of constant observation and record, with particular reference to progress and development. These observations and records should be the constant study of a skilled psychologist or psychoanalyst who would take occasion to periodically counsel with the student as to his predominant characteristics and talents, assisting and directing him to their higher development.

At a later point in the student's career, an organized effort should be made to acquaint him with the opportunities in the field which he is by character qualified to enter, his qualifications being determined not by the character of acquired knowledge that he possesses as defined by the usual academic classification, but rather by the qualities of mind and character that give direction to his energies.

It is not my purpose to attempt to define the organization or system by which this may be accomplished nor to attempt to detail the method of character analysis to be pursued. Presumably a broad general classification will be first attempted, to be followed by more detailed effort.

Types of Men in Industry

For example: Two distinct types are constantly being recognized in industry, namely, the engineering type and the executive type.

The engineering type of man works for the solution of a single technical or engineering problem and is concerned with the determination of the solution rather than the application of that solution to practical activities. The true type has the capacity to concentrate continuously on a single problem until the solution has been reached. He is interested in the determination of cause and effect and of the laws that govern phenomena. He is disposed to be logical, analytical, studious, synthetical and to have an investigating turn of mind. The predominating characteristic that distinguishes him from the executive is his ability to concentrate on one problem to the exclusion of others for a protracted period, to become absorbed in that problem and to free his mind of the cares of other problems. He does not submit readily to the routine performance of a given quantity of work. He deals with laws and abstract facts. He works from textbooks and original sources of information. Such men are Edison, Steinmetz, the Wright brothers, Curtiss, Bell, Pupin, Fessenden, Browning. These men are the extreme of the engineering type, they have enormous imagination, initiative, constructive powers.

The executive type takes the conclusions of the engineer and the laws developed by the engineer and applies them to the multitude of practical problems that come before him. His chief characteristic is that he works with a multitude of constantly changing problems at one time. He concentrates on one problem after another in rapid succession. In many instances he has not the time to obtain all of the facts and he must arrive at a conclusion or make a decision based upon partial knowledge. He must rapidly assimilate available facts and fill in what is lacking from the ripeness of his own experience, frequently calling upon his powers of judgment, and even intuition. He is a man of action, boldness, ingenuity, force, determination, aggressiveness, courage, decision; he is possessed with the desire to get things done, impatient of delay. He works from a handbook, a newspaper or nothing at all. Such men are Schwab, Goethals, Pershing, Farrell, Hindenburg, Hoover.

If we have accomplished nothing more than to assist the boy to determine whether he is a potential engineer or an executive, it seems to me that we have gone a long way.

The question of whether a man has been trained in mechanical engineering or electrical engineering is not half so important as whether he is a real engineer or a real executive. I am sure that we are all acquainted with hundreds of young men who have made their success in some other branch of engineering endeavor than that in which they received technical training, and I feel quite safe in saying that the qualities of character determine a man's success rather than the particular kind or extent of technical knowledge that he has received in his college course.

Perhaps at the same time that the suggestion is made for the amplification of college training so as to include the psychoanalytical treatment of the student, it would not be out of place to suggest that industry take up a similar work on its own account and for its own purposes, with a view to confirming or supplementing the determinations made in the course of college life. It seems obvious that there is a community of interest as between the student, the pedagogue and the industrialist, in that all are seeking the same end, namely, the development to the full capacity of the individual for accomplishment.

We seek only to avoid the wasted energies, the wasted years and the wasted lives; the discredit to educational institutions and the loss to industrial and national life. The limitation upon industrial accomplishment today is men and the industrialist is calling for your assistance in minimizing this limitation. We require men rather than students and intellectualists. Will you give thought to the direction of the human forces which you generate?

The Engineering School and the Industries[1]

By DEXTER S. KIMBALL,[2] ITHACA, N. Y.

ONE of the most remarkable developments in the last fifteen years, perhaps, has been the spread of the use of the word "engineering." The reason for its present extended use is no doubt because we lack some adequate term to employ in its place. What it means is, we are going to extend the methods of engineering to all human activity. First, we have applied it to industry. Now, we are going to apply it to management and then to finance, then to the human element, and lastly to religion. With all this has come also a clear recognition that there is such a thing as the engineering type of mind as contrasted with the legal or medical type. It is a distinct type of mind, one that employes a certain method of attacking problems.

Every graduate of a technical institution views the matter of education through spectacles of his own making. He has some criticism to make or some suggestion for his school's betterment, and many of these have been most useful. Every university faculty welcomes criticisms and suggestions, because they serve to enlighten them as to where they are going and as to what should be done with their curriculum.

In this country the average young man arrives at a university at the age of 17 or 18, and is usually graduated at about 22 or 23. It is not good to have boys stay in the university too long, for their vertebrae become stiff. In the four years allotted to the educator, he must take this young man and try to teach him mathematics and engineering subjects, train his character; he must further teach him English, of which he knows nothing. That, it should be noted, is a criticism on the lower grades of school. He must also teach him something of the classics, and lastly, must turn him out a finished engineer.

The list of things that must be instilled into these young men in four years is a long, long one, and if the faculty to which I have the honor to belong should undertake to incorporate in its curriculum the one hundredth or thousandth part of the suggestions they receive, nothing but chaos would result.

No man can properly be called an engineer who has not studied mathematics, physics and the mechanics of engineering. When it comes to the amount or quantities of these subjects, however, most men who have given much thought to this problem will probably agree that three years are sufficient to give a man a thorough grounding in these essentials of engineering training. This will leave a year in which the boys may be given some knowledge of the other fields about which they apparently ought to know something.

One of the first things that was brought to our attention as a requisite for the engineer was economics. That was not difficult to incorporate. Every engineer is by nature an economist. Every great power house is a problem in economics. The engineer studies economics quite willingly, and it has become a large part of the engineering curriculum.

The next demand—and an insistent one—was for a large amount of work in management, administration. We now have as a last demand this matter of human engineering. The engineer ought to know a great deal about the human element in industry, but generally speaking, he has not in the past been concerned with the human element. It has only been in recent years that he has been brought into touch with this problem; and, it may be said that he has been a little cold-blooded about it. He wants to get things done, and means are ways to an end.

If you are going to have the type of man that does things—and remember that engineers are the great ways and means committee of civilization—you may do other things, but you may not take away those fundamentals and get what I call the engineering type of mind. If I were to make any reply to the industrialist who adds that we do many of these things in the hope of getting men more closely adapted to their requirements, I would say that they, as a rule, have not appreciated either this problem or its solution. The industrial leader has seen fit to criticise the university without offering many constructive suggestions as to how the problem can be solved. One of our great industrial leaders some time ago remarked that if he had his way he would put industrial leaders at the head of all universities. His argument was that the universities are too far away from industry. Well, I hope that they may, in some respects, stay away from industry, and I hope there will always be in this great land universities where teachers are free to teach the truth as they see it. I am free to admit that one of the things that must be done is to give these young men some knowledge of the human problem and related problems, but I do hope there will never come a time when institutions will be adopted by industrialists, who have only in mind the peculiar problems of industry, and have not clearly in mind that the great hope of civilization lies in the engineer, and in making him as ideal as we possibly can.

ENGINEERING EDUCATION DISCUSSION

Dean A. A. Potter of Purdue University submitted a written discussion, in which among other things, he said that our curricula are in general designed to teach students basic subjects which they cannot acquire by their own efforts after they graduate from college.

Mr. Pratt had stated that the engineering schools undertake too early specialization. While the pressure from the outside was great for specialization, a study of the present curricula of engineering schools would reveal the fact that the tendency was to reduce specialization and to broaden the training of the undergraduate.

Carefully kept personnel and academic records should enable engineering educators to discover men who are of the inventive type and who can be developed into inventors, designers and research engineers. The inventive type of student usually shows his talents when very young and his training must be entirely different from that of men who are to enter the fields of production, sales or of public service.

A curriculum which provides no contact with engineering problems during the first two years is bound to discourage many of the more practical and ambitious students.

There is too much tendency in our entire educational system to encourage the development of "one text book" people and without basing the instruction upon the students' ability, aptitude, knowledge and experience. Apparently very little effort is being made to discover and to develop the student's talents.

Statements have been made that there is a distinct need for more highly trained engineers. He would like to have the opinions of Mr. Pratt and of others from industry as to whether we are justified in encouraging students to devote two more years to their preparation. To be more specific, what inducements could industry offer to our exceptional students if we encouraged them to spend five or six years at college instead of four?

M. W. Alexander[1] said that meetings like the one in session were highly desirable, but they would not bring results. It was necessary for the engineering professors and the industrialists in each community to come in close touch, so that the former might learn from the latter of the progress made in the art and the application of the science and of the adjustment that the engineering schools should make as rapidly as possible in order to catch up with the rapidly advancing industries.

A. M. Greene, Jr.,[2] speaking of the demands on the colleges for specialists, said that these were being met by training men whose fundamental work was of such a nature that it prepared them so that they were able to think, reason and apply. Personal contact was one of the most important parts of the work, but, with the increase in size of classes it was growing rather impossible. Some of the best work done in preparing men to go out and solve the

President Carman's Address

ANNUAL MEETING, 1921, THE AMERICAN SOCIETY OF MECHANICAL ENGINEERS

A.S.M.E. Has Emerged From First Epoch Related Principally to Scientific Advancement of Material Things and Now Faces Second Epoch—the Problem of Human Relationships

BEFORE discussing the main theme of my address I desire to relate some of the principal Society activities of the past year. In the year 1920 the spirit of unrest that characterized the human mind as a result of the years of warfare was at its height, and gave expression in most walks of life. It was rampant in engineering society circles, and it is with great pleasure tonight that I give expression to my findings covering the operation of the affairs of our Society.

Our Society is democratic in organization, representative in government—its operation is coöperative—its activities extend into every part of the United States and are within reach of almost every member, and its accomplishments are contributions to the welfare of mankind.

As President I have traveled over twenty thousand miles. I have visited and addressed local sections and business organizations, carrying the message of engineering ability and its relation to the great economic problems of the day.

I have failed to find "politics," or any group of men, or any one man, governing the affairs of our Society.

The San Francisco man has as "much to say" as the New Yorker, and the West Coast members of Council and committees are as conspicuous as those from any other section; North and South, East and West, are united.

There is not anywhere apparent group or faction, friction or discord, except the friendly differences of opinion. We are all one large family, its members helping each other, all working for the upbuilding of our Society.

One year ago The American Society of Mechanical Engineers celebrated its fortieth anniversary. The Local Sections in forty cities held meetings, and with glad hearts told of the accomplishments of the past forty years.

FORTY years of Society activity, and
FORTY cities celebrating;
FORTY—a cardinal number with great significance.

The "Fortieth" Anniversary is used many times to indicate completeness. Israel's greatest kings each reigned forty years, the ancient Venetian court was composed of forty.

Do these first forty years represent the first epoch in the history of our Society?

Has the epoch been completed? All indications point that way, and if it has, then we are now closing the first year of the *second* epoch. In the years ahead I believe there will come the realization that a year ago marked the distinct closing of the *first*, and beginning of the *second*, epoch.

The important accomplishments of the first epoch related principally to scientific advancement of material things. What is to be our aim for the second epoch?

The beginning of the first epoch was coincident with the beginning of a constantly and greatly increasing demand for mechanical equipment and allied engineering projects.

The American Society of Mechanical Engineers has been a splendid copartner in all the technical and scientific developments. It has rendered, and still is rendering, a valuable service to industry.

It was, at its beginning, organized to assist in the solution of the great problems of its day. These problems were technical and scientific in their nature, and their solution contributed to the rapid increase in quantity production, through the aid of mechanical appliances. So rapid and complete was the development that many operations were accomplished with little effort on the part of man. But in many instances the elimination of the effort produced an operation of drudgery—and drudgery always creates dissatisfaction and strife.

If we are to follow the policies of the founders of our Society, we, too, must assist in the solution of the greatest problems of our day.

You will agree with me, I am sure, that the greatest problem of today is neither technical nor scientific, as applied to material things. It is one of human relationships.

If the problem were only the relationship existing as man to man, then it would not be one to be considered by engineers. But our problem is more than one of man to man; it involves not only the relation of man to man, but also the relation of man to production—to intense and mechanical production—of man to waste of production and consumption, of man and his relationship to industry, and of industry and its relationship to man.

In the early developments, engineers as a whole gave attention, in machine design, or plans for large projects involving labor, to the producing of results, regardless of their effect on the person or persons engaged as operators or workmen.

Today it is and should be necessary to consider the human side of quantity production, and since this can best be done in connection with technical and scientific progress, it follows that the engineer, whether he so elects or not, must be the one to assume the responsibility, as the technical, scientific, material and human elements of progress must be considered collectively.

Our problem of today had its beginning in the introduction of machines and mechanical appliances to production; and with the introduction of the labor-saving devices there also began that kind of intense, nerve-racking, vitality-consuming labor that has been constantly continuing and increasing, until it has produced one of the greatest problems that has ever vexed mankind. This problem is commonly called "Industrial Relations."

It is true that the origin of labor trouble can be traced back through centuries, but those are not the labor problems that give expression in organized labor today.

Coincidently with the demand of civilization for great quantities of the articles of its consumption came the necessity for larger industries. As these industries became more numerous, many of them combined and formed large organizations for the purpose of self-protection, self-advantage, and control of markets.

Likewise the bringing together of many workmen, each with a certain and definite task to perform, gave opportunity for an interchange of grievances and a combined or group effort which has resulted in the labor organizations we have today.

Thus we had, growing side by side, two distinct organizations or classes: one, Industry or Capital, the other, Labor Unions or Labor. Not only have both of these organizations increased in size, but each has combined and federated with others of its kind, until both are unwieldy—overgrown, unable to control or direct their followers—each seeking the advantage over the other, and both actually taking advantage of the great consuming class, the Public.

We have still another complication, a third party—the Government—attempting to direct the other two, and the result is more deplorable than ever.

Since the Government is administered by a class which we in America call "politicians," and since each class has its own interests to protect, it follows that no one class should attempt to control the other two.

What, then, is the solution? After years of struggle, after countless endeavors from many different angles, the problem remains unsolved, and growing worse. There must be some method that will solve it.

The party most vitally interested, when rightly led, will be the deciding factor—*public interest is paramount.* What group of men is best fitted for leadership?

The great depression of today has seemingly lessened the apparent necessity for urgent consideration of the problem, but the problem is still with us, unsolved, and with the revival of business it will become more acute than ever.

I recognize in society today the existence of three laws: the

(Continued on page 74)

Prevention of Wastes in Industry

By FRED J. MILLER,[1] NEW YORK, N. Y.

THE Committee on Elimination of Waste in Industry devoted most of its attention to wastes of time and effort because these are far more important than wastes by direct loss of materials.

I think I need not discuss the grosser forms of industrial wastes that come from loss in various ways of supplies and materials. Such losses are relatively unimportant and means of preventing them are now very generally understood and are in use in practically all establishments in which it is realized that the safeguarding of such things that cost money is as important as the safeguarding of money itself.

I am asked to discuss, not simply wastes in industry, but incentives for the prevention of such wastes, and here we are confronted with the anomaly that those who would be supposed to have the greater incentive for the prevention of industrial wastes are found to be responsible for the major portion of the wastes that occur. Responsible, I mean, in the sense that they, the owners and directors of industries, are the ones and the only ones, who can adopt effective means to stop these wastes.

This seems to indicate that not only must there be incentives for the avoidance of waste, but there must be also a clear realization that preventable wastes are occurring and a general understanding of the reasons for them and of the means by which they may be prevented.

It is natural for the normal man to be active in some way—either mentally or physically, or both. There is scarcely a greater punishment that can be inflicted upon him than complete, enforced idleness, such as results from solitary confinement in a dark cell.

It is perhaps industry's chief problem to conserve, develop and make use of the natural desire of the normal individual to be accomplishing something, and, further, to relieve workers so far as possible from such conditions of work as are deadening to ambition, to initiative and to the creative instinct. Far more can be done along that line than may seem possible at first sight, and the results of even the simplest efforts in that direction have, in many cases, been very excellent for all concerned.

In a recently published magazine article the difference was clearly shown between having a foreman tell a group of workers that they must work overtime and, on the other hand, allowing the workers themselves to pass to each other and read a letter from a customer saying that unless his order was shipped by a certain date he would consider himself at liberty to cancel it. The workers themselves decided to work overtime to prevent cancellation of the order. And in all such cases the more ambitious workers can exert an influence upon the others far more effective than any other that can be brought to bear upon them.

Incentives in Industry Defined

Incentives may be grouped in two general classes which may be called the "penalty" class and the "reward" class.

The penalty incentives, in the form of the lash or other gross physical punishments, were more common in slave times than they are now, but the penalty incentive still persists here and there in various forms and there are still too many in our industries who seem to recognize no other kind; not knowing it is still true that "he who owns a slave is himself in chains."

Incentives of the penalty class make people afraid not to do the things they are ordered to do. Incentives of the reward class tend to make people want to do the things that are expected of them. These two classes of incentives of course differ widely in their nature; but they differ no more than the results that are obtained by them.

I do not know what course the discussion of this question may take here today, but I prefer to confine myself to discussion of the reward class of incentives as being the only one worthy of consideration in connection with industries carried on in an enlightened age and in dealing with free men.

The reward class of incentives may be divided into two subclasses that may be called respectively "group" rewards and "individual" rewards.

Profit sharing, group insurance, employee representation or participation in management, most of the so-called welfare work, general or so-called horizontal increases in wages, bonuses paid to all employees alike, etc., are and are intended to be group incentives; while individual increase of wages, piece work, bonuses to individuals for specific individual attainments are, of course, individual incentives.

Whether group or individual incentives should be employed in a given case depends of course upon the circumstances of that case; but my own experience and observation lead me to the belief that, after we have established good working conditions, such as well-lighted, heated and ventilated work places; done what we can to keep them in good sanitary condition and as free as possible from danger of accidents; and have foremen and other executives who have been selected and trained to take an enlightened and "human" attitude toward employees, the rest of the way to the best possible general results is through individual reward incentives; which may take the form of higher hourly wages paid to individuals for individual attainments, a bonus paid for definite attainment, advancement from the ranks to successively higher executive positions, or all of these together with, so far as I have been able to perceive, about equally good results when applied intelligently. And they can be applied intelligently only when means are provided for having a continuous record of every employee's performance with reference to established standards; so that reward incentives will not be based upon any executive's prejudices or whims but upon actual and demonstrated service rendered in doing the work for which the plant is operated.

As a consequence of the acute situation and the very troublous times we have been, and still are, passing through, there has been, I think, some tendency to overelaboration in certain of the measures taken to overcome our industrial difficulties. As for me, I still have faith in the comparatively simple means of enlisting the enthusiastic coöperation of minor executives and employees, and an essential part of this is to give them such treatment as every man likes to receive from those with whom he comes in contact; always remembering that workpeople are not, after all, essentially different from other people; are at least as readily responsive to candid, fair and courteous treatment as are other people, and also as well able to judge whether or not they are receiving it.

Causes of Industrial Wastes Itemized

And along with this there must be avoidance of the large industrial wastes that come from overloaded inventories; slow movement of materials through the successive operations of manufacturing; unskilled, because inadequately studied, and developed, manipulation of materials; inability to definitely and promptly place responsibility for delays; failure to clearly distinguish between those things which are the worker's responsibility, the foreman's responsibility, the superintendent's responsibility, and the owner's responsibility.

That all these, as well as the designing engineer, have their separate responsibilities is, in a general way, well recognized; but in our manufacturing establishments there is usually no means for definitely assigning responsibility in such manner that a record is made, clearly showing to all concerned where the responsibility lies and whose duty it is to take steps to correct the defect, assuming it to be remediable. Such a record does away with arguments and the attempts to shift blame from one to another, until finally it rests upon the man who cannot "talk back," or is canny enough not to do so and must bear it, smarting under the belief that he is unjustly blamed; and being disheartened and perhaps alienated by what he regards as being grossly unfair to him.

The major cause of waste in manufacturing lies in defective administrative methods, for which in general no one is to be seriously

---

[1] Past-President Am.Soc.M.E.

Address delivered at the session on Elimination of Waste in Industry of the Annual Meeting, December, 1921, of THE AMERICAN SOCIETY OF MECHANICAL ENGINEERS.

blamed, for they are the methods that have the sanction of long usage and by them, or rather in spite of them, many successful enterprises have been, and are being, conducted.

Certainly owners and managers are not to be blamed in the moral sense for following well-established methods and practices, and of course they should follow them until they become convinced that there are better methods and practices that are open to them. On the one hand we see employers who are too easily prevailed upon by charlatans to take up methods that are little better than a group of unrelated "stunts," and on the other hand those who always delay progress along new lines until pretty nearly every one else is far in advance of them.

It is the work of engineers to educate and to show the better ways, and I predict that as time goes on our industries will be more and more directed by engineers who know how to direct them for production and who will regard production and service as the prime objects to be attained by an industrial organization. When this change has been effected, one of the greatest causes of waste will have been removed.

I could mention entire industries that are in the control of men who are little if at all interested in production, but devote their entire attention to high finance, which is often crooked finance.

Human Element must be Recognized

All signs point to new conditions under which our industries must be conducted. Improved methods of administration may go very far, but however, along with them, and an essential part of them, if we are to attain the highest immediate success and prepare for still further progress in the future, must be full recognition of the transcendent importance of the human element in our industries, and means simply must be found to remedy and avoid the condition into which so many of our industries have fallen and in which the attitude of employers and employees toward each other ranges from indifference or suspicion to more or less open and avowed hostility and a keen desire for revenge of wrongs, real or imaginary.

Ambitious men must be expected to have ambition for the welfare of their families, and from the social, political and industrial standpoints this is desirable and indeed necessary if our industries are to thrive by rendering service to society.

Foremen must be looked upon and must regard themselves as leaders, inspirers and teachers of their men rather than mere drivers; means must be provided by which the value of workers with respect to a fair standard can be indubitably ascertained and each should be unfailingly rewarded in proportion to his attainments.

Numerous examples, some from my own experience, might be given of the successful working of these principles, but as an illustration of what I mean, I prefer to go back to an incident related by Frederick W. Taylor, mainly because it is exceedingly plain and simple and also exceedingly enlightening to those who will study its full significance.

You will remember that at Bethlehem, Taylor, by patient, careful and really scientific study determined the best type of men, tools and methods for unloading ore from railroad cars. As results, the men were paid considerably higher wages than before, the cost of unloading cars was materially reduced, the men were not worked too hard for their physical well being, and all concerned were satisfied.

An establishment located elsewhere learned of this and hired some of these trained men, Taylor consenting to their going and at the same time telling them he would be glad to have them return if, for any reason, they were not satisfied in their new place.

The men went to work there, working as they had been trained to work, but found they could make no showing because they were only a few working with many others; their contribution to the total work done being therefore relatively small and indistinguishable from the work of the group. In other words, they could make no showing of their abilities.

They asked that they be assigned to definite cars which they could unload by themselves—as they had been accustomed to do at Bethlehem—and were brusquely told to mind their own business and work as directed.

They quit and went back to Bethlehem, and thus the effort to transplant the methods so carefully developed there failed.

And it failed simply because the human nature of these ore shovelers had been ignored; the management did not do its part by establishing the conditions that had been found necessary to success. It was a clear example of the old idea that industrial efficiency is to be secured by simply hiring the best workers available at as low a wage as they feel compelled to accept and then driving them as hard as possible. There may have been also a thought of the pace-making game which has been so much employed and which is still believed in by some employers, though it is extremely crude and the workers have very generally taken such measures as they can to protect themselves against it.

It must be recognized that even in the simplest work pride of achievement can usually be developed, and that often men will work their best only when they are not hampered by conditions that limit their achievements or that prevent them from being credited with their achievements; especially when they know, or believe, that these hampering conditions can be removed.

It would, I think, surprise a great many of us if we could know just how much of the wastes of industry that are caused by careless, inefficient work have a deeper underlying cause in a feeling created by the conditions under which men work, that make them believe they cannot do what they should do, and for reasons entirely beyond their control.

In a certain government establishment to which many good workers came during the war, mainly for patriotic reasons, quite a number of these men quit because conditions there were such that they could not do a fair day's work, no matter how much they might try. They did as much as was customary there, but so much less than they had been accustomed to do that they became disgusted and could not bear to remain.

It is by no means always easy to say where the blame lies for industrial wastes that come from slackness of workers and executives.

Take the case of a machine shop in which it is apparent that not much more than half the work is turned out that should be done. In many such cases the work has been brought up to the full standard by a change in the management, with or without a change in staff personnel, but employing the same workers as before.

Better Management Often Reduces Waste

Too many there are who would, with all the assurance in the world, blame the previous inefficiency entirely upon the employees, but the hard fact that such inefficient establishments have been in many cases vastly improved by change of management or of management methods must be squarely faced if we are to comprehend our problems or succeed in materially improving conditions.

Especially do we need to adopt such methods of management as will enable the facts to be fairly presented to both sides in every difference that arises between employer and employee; and experience shows that when we have done that, both the employer and the employee are far more reasonable and considerate than either usually imagines the other to be.

It is at least as important that all the elements of an industrial organization should work together harmoniously and without friction as that the different parts of a finely designed and constructed machine should do so. When either does not function properly, it is a case for the use of intelligent discrimination in finding out the real cause of the trouble and the proper remedy. Usually the bludgeon treatment only makes things worse, no matter which side resorts to it.

Production has been and is restricted by workers, both organized and unorganized, and most of such restriction is of course wrong, from the economic standpoint, if not ethically.

In most industries, however, I think it can easily be shown that restriction of production by workers is insignificant compared with the restrictions caused by financial juggling of one kind or another; by avoidable irregularity of employment of labor and of plant by presidents or managers who are temperamentally unable to make decisions and then stick to them, or are unable to do so because they are under the control of men "higher up" who know nothing of industrial science, or even that there is any such thing; by unnecessarily large inventories and consequent tying up of capital that could be otherwise usefully employed; by inadequate con-

Forty-Second Annual Meeting of the A.S.M.E.

Sessions Held Under Auspices of Professional Divisions Consider Elimination of Waste in Industry—Honorary Membership Conferred Upon Past-President Henry R. Towne

FIVE solid days of professional and technical features characterized the Forty-second Annual Meeting of The American Society of Mechanical Engineers, and in this respect the meeting was far greater than any yet held by the Society. Not to speak of the social and entertainment features, into these five days were crowded over a hundred professional events. The social events were dovetailed in quite satisfactorily, and though the program was so very full, a well-arranged schedule insured the comfort of all members and guests throughout the week, with the result that there was unanimous agreement that the meeting was a great success. The thanks of the entire membership are extended to all committee members who contributed in any way to this result.

Dexter S. Kimball President, 1922
The American Society of Mechanical Engineers

Notwithstanding the general situation in the engineering industries and the surtax on transportation—the two factors still operating to flatten the attendance curve—the registration was 1854, which compares very favorably with that of previous years. As it was, the facilities of the building were utilized to the full, the auditorium and the meeting rooms on the fifth floor, as well as the "best parlors" of the other societies in the building being in use all the time.

With one set of professional sessions on Monday and Tuesday and another set on Thursday and Friday, and with an all-day Business Meeting in between, there were virtually two "peaks" in the week, and most members from out of town welcomed the opportunity thus afforded to take care of their business and other affairs.

Of the nineteen professional sessions, nine were conducted by the new Professional Divisions, with the result that the technical information brought out was of a high standard.

The Annual Conference of Local Sections delegates was attended by representatives of 44 Local Sections. A more complete treatment of this meeting was given in the first number of the *A.S.M.E. News* issued late in December. It may be said here, however, that in addition to considering the organization problems of the Local Sections, a considerable amount of time was devoted to the proposed Constitution of the Society.

The entire day of the Business Meeting was given over to the new Constitution and two amendments to the present Constitution. The meeting voted to refer the amendments relating to the voting of Junior members and the mechanism of amending the constitution to the membership by letter ballot. The proposed Constitution was referred to the Constitution and By-Laws Committee for further revision and the discussion was carried through purely for the guidance of this committee.

At the Business Session the first award of the A. S. M. E. medal was made to Hjalmar G. Carlson for his invention and part in the production of 20,000,000 Mark III drawn steel booster casings used principally as a component of 75-mm. high-explosive shells, but also extensively in gas shells and bombs. The annual prizes for best papers were also presented at this session.

The meeting of the 1921 Council, with President Carman presiding, was held on Monday, and that of the 1922 Council, with President Kimball in the chair on Friday. The A. S. M. E. delegates to the American Engineering Council attended the Monday meeting and a large part of the time was given over to a discussion of the affairs of The Federated American Engineering Societies. On Monday the Council, the Local Sections delegates and the American Engineering Council representatives met at lunch.

Twenty-seven committee meetings were scheduled on the program, and at least a dozen others were held impromptu. The Society flourishes in proportion to its committee work—the labors of the seven hundred-odd members who contribute their time and experience.

The leading social event was the Dinner-Dance at the Hotel Astor on Thursday evening. Four hundred participated in this delightful affair. The Smoker for the men this year was held at the Fifth Avenue Restaurant, and those who were fortunate enough to attend enjoyed songs, a few clever stunts and a first-class dinner. The President's Reception and the Ladies' Tea were equally enjoyable; they were held on the fifth floor of the Engineering Societies Building which was attractively decorated.

The formal excursions included visits to the Seaboard By-Product Coke Company, the Essex Street Station of the Public Service Corp. of N. J., The Davis-Bournonville Company, the Ford Motor Company, the oil-burning plant of the Singer Building and the S. S. *Olympic* of the White Star Line. The latter was the most popular for ladies as well as the members, and places in the party were at a premium. The steamship company provided tea, and the excursion was delightful as well as instructive.

An innovation this year was a graphic exhibit of the several activities and functions of the Society. This was arranged in the Society's rooms and attracted a great deal of attention and favorable comment.

The account of the Annual Meeting published here deals particularly with the business and professional features. Some of the papers have already been published, others are included in this issue, and the remainder will follow later.

President's Address and Honorary Membership Award to Mr. Towne

ON TUESDAY evening of the Annual Meeting, after an inspiring address in which he portrayed the Society as having completed its first cycle and emerging into a new era, Mr. E. S. Carman relinquished the chair in favor of Dean Dexter S. Kimball, whom the membership had selected to head the Society during 1922.

President Carman's address is published in full in another column of this number.

The ceremony of introducing the new president was carried out after the chairman of the Tellers of Election, Dr. H. G. Tyler, had announced the result of the letter ballot of the membership, taken in the fall, to fill all the annual vacancies on the Council, as well as to elect the A.S.M.E. representatives for the year on the American Engineering Council, the governing body of the Federated American Engineering Societies. The names of all the successful candidates for office were read, and the announcement made that they had been elected by practically unanimous vote.

The new president was escorted to the platform by Past-Presidents Charles T. Main and Fred. J. Miller. In accepting the office, Dean Kimball said that the honor that had been bestowed on him held a peculiar significance, because one of his distinguished predecessors, Professor Sweet, was one of the first teachers at Cornell University, and another, his great predecessor in office at the University, Dr. R. H. Thurston, was the first president of the Society. With the honor, however, he acknowledged a great responsibility and pledged his very best effort to the members and to the Council in keeping the A.S.M.E. in the forefront as the highest representative of best engineering thought in the country.

Henry R. Towne

Past-President Henry R. Towne Honored

A further ceremony of the evening was the bestowing of Honorary Membership in the Society on Past-President Henry R. Towne.

In making the award President Carman expressed great pleasure at the opportunity of reviewing the achievements and attainments of Mr. Towne, and his work for our Society since 1882, two years after its foundation.

Mr. Towne is a Life-Member. He was vice president from 1884 to 1886 and three years later served as president.

In early association with Robert Briggs he carried out numerous experiments in leather belting which were accepted as the standard for twenty years. He formed a partnership with Linus Yale in 1868 which resulted in the organization of the Yale & Towne Mfg. Co., which Mr. Towne directed as President until 1915, since then acting as Chairman of the Board. Mr. Yale having died in 1869, the responsibility and credit for the success of this firm is due largely to Mr. Towne, who greatly amplified original features and embodied with them radical departures in design and workmanship, especially in methods of production which have become accepted standards of the industry. During thirty-six years almost every improvement in locks or lock-making machinery came from the Yale & Towne Mfg. Co. Besides locks as such, Mr. Towne has become famous also as a manufacturer of complete post-office equipment, chain hoists and all manner of art hardware.

Mr. Towne's unusual combination of business and mechanical ability, his keen vision into the future and his untiring efforts to create and maintain a product and service of excellence, have made him the recognized principal factor in the growth and present high position of the lock art.

His contributions to technical literature and especially to the Society's publications have been numerous and basic.

Mr. Towne's Reply

In expressing his appreciation of the honor conferred on him, Mr. Towne recalled some of the early days in the Society, recording how it performed a function of usefulness especially to its younger members, as it does today. Then, as now, it trained its members in the habits of preparation for the meetings and of presenting their work so as to be of interest to others and, he hoped, to the community. In other words there has always been the thought of service. In this Society service belongs properly first to our fellow-members, then to the Society as a whole, the profession, and lastly to the community.

He thought that young men were apt not to realize this possibility of service in their work, and yet it underlies work of all kinds, and especially that of the engineer.

During the latter half of the long period of his membership his time and attention had been turned largely from purely engineering matters to those connected with the great city of New York, and sometimes to affairs of the nation. But in all these duties in which he had been able to render service, he had been aided by the fact that he had not only a technical training but also considerable experience in the practice of engineering and in the art of management. Therefore those of the younger men who have similar training and experience are particularly qualified to act as leaders in civic affairs, and he urged that without slighting their professional work they seek opportunities to engage in activities of this kind.

Reception of New Officers

Following the exercises in the Auditorium the company adjourned to the reception rooms where the new officers received the members of the Society and the ladies. Then came the customary informal get-together, with the renewal of old associations and the formation of many new ones. Music was provided, and the evening ended with an informal dance.

Opening Session on Waste in Industry

In announcing the general topic of the Annual Meeting of The American Society of Mechanical Engineers as Elimination of Waste in Industry, President Carman voiced the sentiment that in the years to come the deliberations of this convention would be looked upon as the inauguration of a practical program for waste elimination, not only in industry, but in all walks of life. It was traditional that the American people were wasteful, probably because of the great wealth of their resources, but he emphasized that the present was witnessing the inauguration of a program of economy which would redound to the credit of our nation.

Explaining that elimination of waste is largely a matter of management, the President said that the Management Division of the Society, now numbering upward of 1600 members, had contributed the program of this session, and he therefore introduced as presiding officer former chairman of the Division, Mr. L. P. Alford, vice-president of the Society.

Mr. Alford told of the interest, publicity and favorable comment that has been accorded to the report of the Committee on Elimination of Waste in Industry appointed by the American Engineering Council of The Federated American Engineering Societies. He felt, however, that if elimination of waste is to be put into practical effect in American industry, this must be done through

the individual acts of the engineers in the several professional societies.

Turning to the program, Mr. Alford then presented Past-President F. J. Miller, whom he also introduced as contributing to the Report by taking charge of the field investigations in the metal industries. Mr. Miller's message to the convention appears in another column.

Prevention of Waste of Power

In introducing the next speaker, Mr. Alford said that Major Miller had stressed the human waste in industry; Prof. L. P. Breckenridge[1] would present another point of view—the elimination of waste of power, to be made possible by a proposed consolidation of all sources of power in the country's great industrial zone from Boston to Washington.

Professor Breckenridge, speaking as chairman of the Advisory Committee of the Superpower Committee, described how emissaries from the Engineering Council had appeared before Government authorities and helped to secure an appropriation for a research or survey to determine what, if any, waste might be prevented by the development of what has come to be known as the Superpower System. The report of this survey,[2] made with the coöperation of 18 railroads, 558 public-utility companies, and the information reported through the census of 76,000 industries using power within the zone, is now available. The essential elements of the superpower plan are:

(*a*) Generation of power in plants of large capacity and high economy
(*b*) Locating those plants advantageously relative to coal, mines, condensing water, load centers and coal distribution
(*c*) Electric trunk lines in connection with the generating stations, both steam and water
(*d*) Unified system of control in charge of a power despatcher
(*e*) Delivery of primary power to electric public utility
(*f*) Local distribution of energy by the public utilities.

This latter includes the essential element of a superpower plant in this or any other zone.

Predicated upon curves extended into 1930, the expected economies are:

(*a*) Annual saving of 50,000,000 tons of coal
(*b*) Annual saving of $240,000,000
(*c*) Elimination of coke and its attendant wastes
(*d*) Elimination of waste of water power.

The other important effects will be:

(*a*) Material reduction in price of power
(*b*) Considerable transfer of coal transportation from land to water
(*c*) Increased flexibility of power distribution
(*d*) Opportunity for coal storage, tending to stabilize production
(*e*) Establishment of chemical, metallurgical, and other metal industries needing large power supply and high temperatures.

The superpower zone covers two per cent of the area of the United States, contains 32 per cent of the population, and manufactures 44 per cent of the products of the country.

The scheme of the superpower system is a large one, but it is the next logical step in the conservation of power resources. Following the survey of the facts will come studies of the local conditions under which the system can be installed, and finally the study of the financial conditions to take care of it.

Prevention of Waste of Money

The third speaker was E. F. DuBrul,[1] who directed attention to the tremendous wastes in industry caused by industrial depressions in business cycles. Within a century this country has passed through fourteen periods of depression of greater or less extent, but all involving serious loss to the investor in industrial enterprises.

Liabilities of concerns which failed in the past ten months of 1921 aggregated $591,000,000, but even this figure does not represent the wastes of investment, loss of useful values, loss of profits and wages in concerns which did not reach the bankruptcy court.

On all sides we are told that these losses are due to maladjustment of supply and demand, but this occurs because those responsible for supply know so little about the demand for their product that for considerable periods they purchase far more supplies than they need, and they waste capital in building plants to supply a non-existing demand.

If there are 9,000,000 automobiles in the country, each consuming four tires a year, or 36,000,000 tires in all, is it not waste of capital if 75,000,000 tires are manufactured for replacement?

This kind of error must be placed at the door of management, and can be avoided only by the coöperation of managers with each other in a study of the facts as to supply and demand of the commodities they produce.

However, the new economic conditions are compelling attention and business cycles are being studied as never before. Men are beginning to promulgate a fallacious gospel—that the end of business must be *service*, not production, not profit. Service is a means of gaining profit, and all business without profit dies—the controlling factor in management must be a financial factor—it stands the losses and it gets the profit where there is one.

In the last analysis, therefore, the controlling waste in industry is financial waste, and it seems not to be asking too much to ask management to eradicate this waste by recognizing its duty of adjustment of supply and demand.

Discussion of the Three Papers

The meeting was fortunate in having in attendance Mr. W. S. Murray, the Director-Engineer of the Superpower Survey, who supplemented the remarks of Professor Breckenridge by a visualization of the "point to be striven for" by the coöperation and coördination of all utilities within the zone, finally producing on the map such a system as some 500 engineers had agreed upon as a good mark for which to aim.

Mr. Murray was followed by Mr. H. W. Flood, secretary-engineer of the Survey, who demonstrated that the concentrated-power system, besides reducing fuel costs to about one-half, would also reduce labor, maintenance and supplies to about one third of those for independent operation as of 1919; accordingly, in discussing waste, it is important to add to the conservation of fuel, the saving of labor and capital.

Mr. J. Parke Channing, Chairman of the Committee on Elimi-

nation of Waste, said that in stating that management is responsible for 50 per cent of the waste in industry, it is fair to say that all men who represent management are not engineers. In those industries in which engineers are prominent as managers and directors, there is and will be less waste than in those in which engineers do not fill their proper place.

Mr. W. N. Dickinson,[1] referring particularly to Major Miller's paper, said it was not brought out clearly that one of the incentives of industry is pride. Belief that industry is moving toward some worthy goal, and pride that his organization is a leader in that progress, will work as fully in a man's mind as the promise of financial recompense.

Lewis F. Lyne, Jr.,[2] said that he had "boiled down" the *causes* of waste to negligence, lack of initiative, ignorance and poor service, and the *remedy* to replacement of management by people who have the necessary ability to handle these inherent discrepancies.

Speakers on Elimination of Waste at Leading Session of A.S.M.E. Annual Meeting

Left to right, back row: Ernest F. duBrul, L. P. Alford; front row: E. S. Carman, L. P. Breckenbridge, W. S. Murray, F. J. Miller.

George Vangelder[3] stressed the sociological side of waste. Is the problem the question of handling material and planning production, or should we use these things for the purpose of building up a better manhood in the country?

The incentive which made every worker in this country produce in the war is the incentive that the manufacturer must give his employee now—to produce, not for profit alone, but for building up industrial America.

R. A. Wentworth[4] combined the service and the profits motives of industry, disagreeing with Mr. DuBrul that the aim of industry is profit. This speaker referred to the work of the late Mr. Gantt, whose life was founded on the principle of service.

In his own experience he had never seen any deviation from the truth that sufficient knowledge of the problem, adequate observation of the facts and sufficient initiative in applying the remedy, could keep any business out of its trouble.

Mr. DuBrul, in his closure, challenged the discussion of his statement that the end of business was profit. He agreed that the means for profit was service, but that did not change the fact that the end of business was profit. There was never a business started for any other reason than profit.

Education and Training in the Industries

Monday evening was given over to a session dealing with the vitally important problem of education and training in the industries. The program was arranged by the Committee whose activities have been devoted to this subject under the chairmanship of W. W. Nichols.

An unusually interesting paper was presented by Dean R. L. Sackett, who outlined methods of education and training actually being used in industry in this country and abroad. The development of education and training in the railroad field was treated by D. C. Buell. These papers and the strong discussion incited thereby will appear in the February issue of Mechanical Engineering.

Public Hearing on Proposed Code for Unfired Pressure Vessels

An important hearing was held on Monday, December 5, by the A.S.M.E. Boiler Code Committee to discuss a code for unfired pressure vessels, a preliminary draft of which has recently been issued. This pamphlet was the result of over two years of investigation and conferences with allied organizations.

The contributions of the Sub-Committee on Welding to this code are shown in the proposed specifications for autogenous welding, forge welding and brazing. While there was the attempt to render the code comprehensive, every detail of either the construction requirements or the various specifications on which there had been lack of agreement, was omitted. These points of possible disagreement were presented for discussion in a list of fourteen questions at the end of the report.

This preliminary report had been distributed in advance of the meeting to nearly 500 individuals and concerns known to be interested in the manufacture or use of unfired pressure vessels. The result was an attendance averaging nearly 200 during the entire day.

The preliminary draft of the proposed code was read paragraph by paragraph and discussion invited on each detail. The responses to the fourteen questions at the end of the report furnished the Committee with data valuable for use in shaping the code into final form. The Boiler Code Committee will give this data immediate and careful consideration so that the revised Code will be presented for further discussion, possibly in connection with the Spring Meeting of 1922.

Power Session

Four notable papers giving actual heat balance figures in three large public utility plants and the proposed scheme in a plant under construction were presented at the Power Session on Tuesday morning.

These papers presented valuable data that had not previously been made public and drew, therefore, a wealth of discussion. The three following papers appeared in the December issue:

MACHINE SHOP WASTE SESSION

At the Machine Shop Waste Session, held on the morning of December 6, F. O. Hoagland presiding, two papers were presented, namely: Salvaging Industrial Wastes, by J. A. Smith, and On the Art of Milling, by John Airey and Carl I. Oxford. In addition to these two papers, which were published in abstract form in the December issue of Mechanical Engineering, an inspiring address on Waste in the Machine Industry was made by Mr. J. J. Callahan.[1] Mr. Callahan told of the benefits that had been derived in numerous instances by enlisting the interest of the workers in the problems of the management.

Discussion on Salvaging Industrial Wastes

Luther D. Burlingame[2] said that true salvaging might come by not having the scrap heap but by having parts so available that they were not to be had by merely picking in a pile. High-priced executives of shops or mechanics hunting for such things meant a waste of money. Another point was the importance of impressing on foremen, executives and others, the real value of salvaging materials.

A. L. De Leeuw[3] told of experiences with the Singer Manufacturing Co., where for a number of years several of his staff were constantly engaged in attempting to save some of the materials that were constantly being used in the shops, such as cotton waste, lubricating and cutting oils, belting, metal chips from machine tools, etc.

F. Eberhardt[4] discussed briefly waste prevention in machine castings. Carl G. Barth[5] gave examples of waste he had encountered in a large car works.

Discussion on the Art of Milling

Professor Airey in presenting his paper called attention to some experiments made since this paper went to press, which related particularly to the consumption of power to cutters. The particular type of cutter compared is known as the right- and left-hand spiral cutter. It is an alternating spiral where successive teeth are formed on the opposite spiral. They had compared this type of cutter with one having all the teeth running in the same direction and found the alternate spiral to show a saving of between 20 and 30 per cent, depending on the material being cut. That represented considerable saving where a cutter consumed a lot of power. A cutter consuming 15 hp. in a nine-hour day would require 100 kw-hr. Effecting a saving of 20 per cent in the power required for that particular operation, would be a saving of 20 kw-hr., which at the Detroit rate of 3 cents per kw-hr., would be 60 cents per day on one small milling operation.

A. L. De Leeuw submitted an extended written discussion of the paper from which extracts follow:

It is to be regretted that the authors did not go a step further and attempted the separation of a chip by a very slow process, so as to enable them to observe the deformation of the metal at the different stages of separation, either by direct observation or by the moving-picture method.

The authors' determination of the direction, location and magnitude of forces in horizontal and vertical directions is somewhat along the line of Nicolson's experiments and, in the writer's opinion, deserves the same criticism. One of the chief requirements of machine-tool construction is rigidity, because it is well recognized that the lack of this rigidity increases certain of the forces or at least increases their effect on the work to an extent altogether out of proportion to the amount of lack of rigidity. Therefore, to place the work on movable pistons is to go away from the very essence of machine-tool design.

A milling chip tends to start with a zero thickness and, consequently, the cutter must slide over the work for some distance before it will be able to penetrate. The tooth, however, enters the work suddenly, so that, as a matter of fact, the chip as it is actually produced does not start with a thickness zero. Instead of having the theoretical shape as shown in Fig. 1, it will actually have the shape as cross-hatched in Fig. 2.

The observations about rake are closely in accord with the results the writer found in tests made between 1907 and 1914. The existing differences may be explained away by the fact that in his experiments part of the power consumed was used for feed.

Referring to the paragraph entitled, Effect of Clearance: Previous tests have shown the same result brought out by the authors namely, that clearance has no effect on the power consumption. However, it does have an effect on the life of the cutter and the finish produced. It seems that gritty materials require more clearance than those which will produce a continuous chip.

Early in the paper the authors state that as a chip thickens, metal is removed more easily per unit volume. As a practical rule, this statement is acceptable and meets all shop conditions. As a statement of accurate fact, it may be doubted. A number of observations made by the writer of this discussion showed that the efficiency increases when the cross-section of the chip approaches more and more a perfect square.

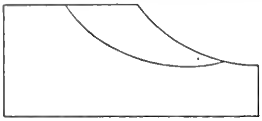

FIG.1.

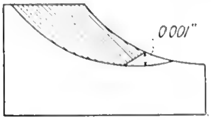

FIG2.

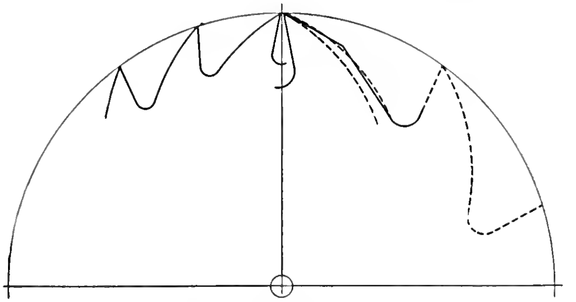

FIG.3.

Fig. 1 Theoretical Shape of Chip; Fig. 2 Actual Shape of Chip; Fig. 3 Recommended Proportions of Teeth

The writer must take issue with the statement contained in Par. 50 and following paragraphs. If the only point for consideration were the power required to remove a cubic inch of metal, the conclusions reached by the authors of the paper would be quite correct. However, in practice this power consumption was only one of the elements to be considered and not necessarily the most important one.

In a large portion of all milling work, one cut only is taken which is required to produce a finish of sufficient fineness. This finish depends on the number of revolution marks per inch. As a matter of fact, in a large percentage of all cases, the feed per revolution is limited by the desired finish at least as much as by the ability of cutter or machine to take the cut. The authors of the paper seem to be under the impression that the underlying idea for the introduction of the wide-spaced cutter was to supply sufficient chip space. As a matter of fact, this consideration only explains their origin. It was the observation of a case of insufficient chip space which induced the writer to try a somewhat wider spacing. Subsequent tests with these wider spaced cutters brought out further advantages.

In selecting the proper kind of cutter for a milling job, the following line of reasoning may be considered typical for a majority of cases:

The nature of the work compels us to limit the distance between revolution marks to, let us say, 0.050 in. In order to do the job as quickly as possible we must have as much feed per minute as

possible. The feed per minute depends on two elements: cutting speed, and size of cutter. With the material to be cut and considering the depth of cut, we will be limited to a cutting speed of, let us say, 70 ft. per min. We must now select the smallest possible cutter which will do the work in order to get the greatest possible number of revolutions which will give 70 ft. cutting speed. Now enter such considerations as size of arbor, depth of teeth, size of keyway—all of which may prevent us from making the cutter as small as we would like to have it. If, for instance, we are compelled to use a fairly long arbor, we must make that arbor of sufficient size to avoid excessive bending and torsion. Having considered all these items we finally decide on the size of cutter. As we want to do the job with as little power consumption as possible, we must provide for taking the heaviest possible chips, and this in its turn means the smallest possible number of teeth in the cutter. It will be noticed that this line of reasoning is almost diametrically opposed to that followed by the authors of the paper. There are certain limiting conditions which prevent us from making the number of teeth as small as might be desirable. To have too great an angle between two adjacent teeth would mean that in practically no kind of cut would we have more than one tooth buried in the metal. To avoid the resulting hammer blow, we must put a sufficient number of teeth in the cutter.

Some of the Participants in the Machine Shop Session
Left to right, back row: F. K. Hendrickson, H. S. Beal, C. J. Oxford, H. J. Eberhardt, front row: H. P. Fairfield, Carl G. Barth, F. O. Hoagland, John Airey.

The original reason for the reduction of the number of teeth of a cutter was chip space. Soon afterward it was found that the power consumption was smaller and that, as a result, a given-size milling machine was capable of taking heavier roughing cuts with the wide-spaced cutter than with the older type. Other advantages showed up later on. Among these advantages are the fact that under many conditions a wide-spaced cutter will finish more pieces before it becomes necessary to resharpen it.

Not only does a wide-spaced cutter require less sharpenings, but it will stand many more sharpenings. Furthermore, it requires less time to sharpen a cutter with few teeth than one with many. It should be understood, however, that Mr. De Leeuw does not recommend the widest possible spacing for all imaginable cases of milling.

Besides the reasons mentioned, there are other reasons which may prevent us from taking the heaviest possible chips. In many cases it is not possible to clamp the work down in a sufficiently rigid manner to withstand the pressures accompanying heavy chips. In other cases, the piece of work may be of such a character as not to allow heavy cuts to be taken, either because it is too frail or because the heat generated will distort the piece, or both. In order to obtain the greatest possible economy in the milling operation, we must give the cutter the greatest possible number of revolutions and, after we have selected the smallest practical cutter, there is only one source of economy left and that is to increase the cutting speed. It was considerations like these that led up to the system of stream lubrication whereby unusually high speeds can be obtained with some intelligence and care. As stream lubrication not only prevents the cutter from heating unduly, but also keeps the work cool, it has a double effect on the economy of milling operations.

The foregoing considerations led the discussor to take exception to the statements contained in Par. 62. (As many teeth as possible.)

Fig. 3 shows the proportions of teeth as recommended by Messrs. Airey and Oxford, and also those recommended for wide-spaced cutters. The sketch shows a $3^1/_2$-in. cutter enlarged four times. The left-hand side shows the teeth as formed by the formula given in the paper and with twenty teeth in the cutter. The right-hand side shows the teeth, in black, as they are actually made; and in broken line as they would be made according to the formula given in the paper. It will be seen that there is but little difference between these two shapes—the actual shape being slightly the stronger. The main difference, however, lies in the fact that the broken-line shape requires a specially made cutter for generating the backs of the teeth, whereas the black shape can be formed by any cutter. When the land, as originally furnished, becomes too wide, it is a simple matter to grind the backs of the teeth with a cup wheel and to repeat this action as often as is necessary. So long as the size of the land is not reduced beyond the original size, the strength of the tooth will not be impaired. It is this practical reason which makes me advocate the shape as shown on the right hand side of the sketch.

Earle Buckingham,[1] who orally discussed the paper, was very much interested in the results obtained when using a spiral cutter, and offered the following explanation why these should show less effective results, namely, that the area of the surface of the cutter in contact with the chips becomes greater as the rake angle is increased thus creating more friction. This might explain the results obtained from using lubrication. The chips from some materials curl up more than those from other materials. If the chip clung closely to the face of the cutting edge, the lubricant might cause the chip to wring to the face in much the same manner as two gage blocks are wrung together, thus greatly increasing the friction. An analysis of the character and shape of the chips produced from different materials with the use of cutters of varying rake angles might shed some light on this.

The authors state that "the fine-tooth cutter will wear longer between grindings, due to the decrease in cutting speed." Too much emphasis cannot be given to the fact that a decreased cutting speed greatly increases the life of a cutter between grindings. The proportional increase in life is much greater than the proportional increase in speed. The speaker is acquainted with some very interesting tests made some five years ago to determine the effect of cutting speed on the life of a cutter. Tests were made at speeds of 70 and 80 ft. per min. with high-speed steel cutters on small nickel-steel forgings. The results were very consistent and showed that when running at 70 ft. the cutter would mill over twice as many pieces as when running at 80 ft. Thus two cutters of the same diameter, taking the same feed per tooth so that each would remove the same amount of material in the same time, etc., but with 21 teeth in one, for example, and 24 teeth in the second, would show a great difference in their life between grindings. If the conditions were identical to those mentioned above, the 24-tooth cutter would mill twice as many pieces. Thus should make apparent the importance of tooth-numbers in milling cutter design.

Frank B. Gilbreth[2] called attention to the fact that there was a field open to the makers of machine tools today which had not been utilized in the least, namely: The photographic record of the behavior of a tool and of the chip. It was now possible to take 2500 pictures per second stereoscopically with a penetrating screen.

Professor Airey, in closing the discussion, said that stereoscopic recording suggested by Major Gilbreth was the logical next step. They had done some slow-speed work in that field. They had taken ten or fifteen minutes to take out one chip, and had made records taking it in instalments.

Regarding Mr. De Leeuw's remarks on rigidity he was in accord with those. That was a fundamental, regardless of the particular cutting tool. As for the sharpness of the tool, not being capable of being absolutely definite, the test of that was in the machine

---

[2] Pres., Frank B. Gilbreth, Inc., Montclair, N. J. Mem.Am.Soc.M.E.

belt. The author had realized that that was a possible source of trouble. They took from fifty to one hundred tests, and found they had to take a great number of chips, but there was no change in the energy, which was proof that the sharpness remained unimpaired. The chip thickness was zero at times, but it was known that the cutter could not get under the surface all at once. Just when it did get under we do not know, probably the photographing would clear that up.

Railway Session

The problem of eliminating waste in locomotive and car design and operation was given intensive treatment at the Railway Session on Tuesday morning. Two of the papers which were presented at this session had appeared previously in Mechanical Engineering. These are Avoidable Waste in Locomotives by James Partington, in the November issue, and Avoidable Waste in Car Operation, by Walter C. Sanders, in the December issue. The remaining paper, on Avoidable Waste in Operation of Locomotives and Cars, by William Elmer, will appear in the February issue with an abstract of the entire discussion at this sesions.

Gas Power Session

The Gas Power Session was the first to be held by the reorganized Gas Power Division of the Society. With B. P. Flint, a member of the Executive Committee of the Gas Power Division, in the chair, two papers were presented, one by Louis Illmer, on the Porting and Charging of Two-Stroke Oil Engines, and the second by Elmer A. Sperry, on Compounding the Combustion Engine. There was practically no discussion on Mr. Illmer's paper and the meeting accordingly took up Mr. Sperry's paper, which appears elsewhere in this issue of Mechanical Engineering.

In the opening discussion George A. Orrok[1] called particular attention to the transfer valve between the high- and low-pressure cylinders, which in Mr. Sperry's engine is the solution of a particularly severe problem. Mr. Orrok also emphasized the importance of mechanical atomization of fuel which has proven so successful when using fuel oil under boilers. He pointed out that the engine described by Mr. Sperry followed canons of steam-engine design.

Francis Hodgkinson[2] pointed out as important the increase of the size of compression space, which leads to detonation and is a remarkable aid to good combustion. A number of questions were asked as to the efficiency that could be obtained in this engine, and in closing the discussion Mr. Sperry stated that its thermal efficiency approaches the theoretical air-cycle efficiency, while the mechanical efficiency in the engines thus far constructed has been about 93 per cent. Mr. Sperry also outlined the possibilities of increasing the sizes of the compound engine and stated that with a 29 in. cylinder and a piston speed of from 800 to 900 ft. per min. there would be no difficulty in getting an 8000-hp. engine.

MANAGEMENT SESSION

The MANAGEMENT Session at the Annual Meeting was presided over by Mr. L. P. Alford, Vice-President of the Society and former chairman of the Management Division.

As a basis for discussion of the central theme of waste elimination by efficient management, three papers were presented: Making Work Fascinating as the First Step Forward Reduction in Waste, by Walter N. Polakov; Process Charts, by Frank B. and L. M. Gilbreth; The Rochester Shoe Wage Arbitration, by Sanford E. Thompson, and two reports: Report of the Sub-Committee of the Management Division in Management Terminology, and Report of the Sub-Committee in Measuring Managerial Ability.

Mr. Polakov's paper was published in the December issue of Mechanical Engineering; that by Mr. and Mrs. Gilbreth appears in this number, and Mr. Thompson's will be published later.

Written Discussion is Voluminous

Mr. Gompers wrote that the human element in production is the most important one, and labor realizes that upon management devolves the responsibility of developing the technique necessary to provide the methods whereby the creative ability we seek to conserve shall be released through opportunity to use brain, skill and human power in production.

Some of the written discussions of Mr. Polakov's paper were papers in themselves. For instance Mr. A. L. De Leeuw contributed a discussion of 3600 words, ascribing the entire causes of unrest to the demoralization of the world, and criticizing most palliative systems as failing to touch the underlying foundations.

Like Mr. De Leeuw, most of the discussors agreed with the author and their contributions were therefore more of the nature of supplements to the paper. However, L. W. Wallace, while praising the paper highly, could not concur in the statement concerning time studies. He wrote that he had not realized that there was any conscious effort being made towards decentralization of planning, nor of reuniting, instructing and inspecting functions of foremanship nor of substituting time-study with direct interchange of workers' skill and intelligence. It seemed to him that conscious effort in this direction would be a backward step and not absolutely necessary in removing the element of monotony.

Ralph L. Paddock wrote that the paper was filled with many opportunities for differences of opinions. However, he granted that by keeping well within the bounds of well-known facts the author proved his point.

Flattering the individual worker by calling him a "super-animal" and making his job more interesting, Reynold A. Spaeth agreed was essential for successful production, but he thought he saw signs of a deeper dissatisfaction—the monotonous grind of working perpetually for the interests of others, never for oneself.

Dr. H. S. Person[1] said he could not speak too strongly of his agreement with the central idea of the paper, but he told Mr. Polakov he intended to emphasize the points of disagreement. He thought the author used unnecessary philosophy, that he weakened his argument by a one-sided industrial history, that he explained the Taylor philosophy and system of management incorrectly, and that he did not concede to the personel manager sufficient credit in solving the problem of management.

Process Charts, by F. B. and L. M. Gilbreth

Characterizing Mr. Polakov's paper as being concerned with the "why," Mr. Karl G. Kaisten wrote that Mr. and Mrs. Gilbreth's paper dealt with the "how." Mr. Polakov promised mankind a social system, while Mr. Gilbreth's paper "disclosed marvelous powers of dissecting human motion and activity." One paper was a "telescope" and the other a "microscope" and argument between them would be absurd.

Fred. Colvin[2] wrote that the authors' methods overcame the one great trouble with most records which are usually so delayed that they become merely post-mortems after the job is finished, and are not even always of value for the next job. It is not easy for either executives or workers to change their methods and habits, and an understanding of this phase of human nature is the first step toward efficient management.

M. L. Cooke[3] asked for information regarding the relation between the process chart and the route and instruction chart, and Mr. Gilbreth replied that the process chart is a definite scheme of visualizing the thing to be done. After the process chart comes the route chart and thirdly the instruction chart.

Elimination of Waste Through Wage Adjustment

Mr. Sanford E. Thompson[4] was introduced as an arbitrator selected by the United Shoe Workers of America, in the Rochester Shoe Wage arbitration. His paper, which will appear later, described the events leading up to this arbitration and says "In the arbitration proceedings which resulted, there was presented by the workers as a substitute for wage reduction, a plan designed to lead up to the elimination of waste in manufacture through scientific methods, and the adjustment of wages on a scientific

[4] 136 Fedral St., Boston, Mass. Mem.Am.Soc.M.E.

basis involving job analysis and time study." Then follows the award, a description of the Arbitration Board, and a brief treatment of the proceedings.

Mr. Thompson then discussed the two broad questions of: (1) Must wages come down, and if so how much, and when? Shall it be a flat charge or a real adjustment? (2) How should the workers themselves share in wage determination; illustrating his points with examples for the Rochester case.

As bearing in the problem of elimination of waste, Mr. Thompson quoted in extenso the proposal of the Arbitration Board for the permanent solution of both the wage and production problems:

"(1) That no wage reductions be recommended by the Board

"(2) That the existing piece-work and wage rates be placed on a strictly scientific basis as rapidly as the organization of joint administrative and technical machinery to this end will permit.

"In order to accomplish the purpose outlined in this proposal, the Shoe Workers request that joint administrative and technical machinery be established, based on the early recommendations of three technically qualified individuals, one selected by the manufacturers, one by the shoe workers and the third by the Arbitration Board. The duties of this committee are to be:

(*a*) To make a rapid survey of the Rochester Boot and Shoe Industry, *from the point of wastes and inefficiencies* and industrial relations.

(*b*) To determine the type and detailed organization of the coöperative administrative and technical machinery which the manufacturers should adopt for the purpose of establishing production standards.

(*c*) To suggest ways and means for *permanently remedying existing wastes and inefficiencies* in the local shoe industry.

(*d*) Pending the establishment of the scientifically correct production standards, and the elimination of wastes and efficiencies, existing piece work and wage rates shall not be lowered.

Reports of Subcommittees Presented

Mr. F. E. Town,[1] in presenting the progress report of the Joint Committee on Management Terminology, defined the scope of this work:

(*a*) to define management, and list and define the terms and phases of management

(*b*) to extend the Dewey decimal classification to cover management literature.

He described the organization of the committee—with six societies participating, each with two representatives and an alternate, and then outlined the work that had been done to date.

Four sub-committees were appointed, on Society Coöperation, on Ways and Means, on Finance and on Program.

The committee has succeeded in making a master alphabetic list of management terms, also a list classified under four groups for convenience, and these lists have been sent out to some 230 colleges which have promised to coöperate in supplying definitions of these terms and doing the necessary research work.

A vote of thanks was extended to the committee for their progress so far.

The second report presented was a prelimary report by the Sub-Committee in Standardization of Graphics. Mr. J. J. Swan[2] presented this subject, stating that the purpose of this committee was to standardize the "short-hand methods of presenting business, industrial and technical data."

The work of the committee was only just started, and the members would be very glad to receive suggestions from anyone in the Society.

The third report, on a Study of the Units and Methods of Measurement of the Managerial Function, was presented by Mr. A. L. De Leeuw.

The functions of management consist of three items: Promotion (and Extension), Production and Sales. In order to confine itself to that part of the investigation which would offer the best promise of results in the near future, the Committee had worked only on the managerial function concerned with Production. This in turn is manifest in three directions: Organization, Preparation and Direction.

Under the heading of Organization we have the Evaluation Chart, prepared by the Waste Committee, under Preparation, we have such items as Time Study, Motion Study, Basis of Wages; and under Direction, we find control charts.

The report recommends the consideration of ways and methods to obtain the necessary data required for:

Organization
  Balance of Responsibility and Authority
Preparation
  Effectiveness of purchasing
  Adherence to standards
  Basis of wages in Industry
  Balance of sales and production
Direction
  Labor stability—factor and data
  Labor attendance—factor and data
  Continuity of working conditions—factor and data
  Material turnover period—factor and data.

At the close of the discussion of this report the following motion was passed:

That a vote of appreciation be accorded the committee, and that they be asked to continue the study and present their conclusions to the Management Division, and thirdly,

That the Executive Committee of the Management Division consider the advisability of asking the American Engineering Council to undertake an investigation of a basis for wages in industry.

Forest Products Session

The problem of conservation of forest products was given careful consideration at the meeting of the Forest Products Division. The principal speaker was David L. Goodwillie of Chicago, Ill., who told of the work being done by the United States Chamber of Commerce in their appointment of a Commission on Conservation and Reforestation. This Commission of twelve has traveled through thirty-seven states and has met with the men in the different branches of the lumber industry who are interested in a national policy for forest conservation. The effect of taxation on conservation, the importance of waste utilization, the control of competition and the restriction in timber cutting were all discussed. Mr. Goodwillie told in detail of the project at Bogalusa, where every portion of the lumber and waste is being utilized in factories where the handling is done entirely by machinery. The plans are laid with remarkable vision and the regrowth of timber in a comparatively short time is actually being accomplished.

Dr. Hugh P. Baker, of the American Paper and Pulp Association, told of the various methods of reforestation that will permit of a greater utilization of waste timber land. Discussion was contributed at this meeting by Joseph H. Wallace, George M. Hunt, Paul Porter, and Dr. Cruikshank on various methods of increasing the utilization of forest-products waste. Mr. Goodwillie's talk and the consequent discussion will be given more complete treatment in a later issue of Mechanical Engineering.

Fuel Session

The Fuel Session was held Thursday with Professor L. P. Breckenridge, Chairman of the Fuels Division, acting as presiding officer. The program of excellent papers filled the auditorium and elicited a great deal of interesting discussion. Abstracts of the papers have appeared in Mechanical Engineering. The paper by Victor J. Azbe on Boiler Plant Efficiency appeared in the November issue as did the papers by Joseph Harrington on Fuel Saving in Relation to Capital Necessary and by W. B. Chapman on Gas Producers and Industrial Furnaces. The masterly contribution by Dr. D. S. Jacobus appeared in December Mechanical Engineering. An account of the discussion will be brought out in the February issue.

Elimination of Waste Through Efficient Materials Handling

THE Materials Handling Division of the Society, comprising 1400 members, staged a session on Thursday afternoon of the Annual Meeting, devoted to Materials Handling an Important

---

[1] 250 Eleventh Ave., New York, N. Y., Mem.Am.Soc.M.E.

[2] 30 Church St., New York, N. Y., Mem.Am.Soc.M.E.

Factor in the Elimination of Industrial Waste. Mr. Robert M. Gates, the active chairman of the Division, presided, and Mr. H. V. Coes, a member of the Division's Executive Committee, presented the one paper of the afternoon, which was discussed at great length. This paper was published in the December issue of Mechanical Engineering.

In presenting the paper, Mr. Coes stated that there was a great lack of information as to the best materials-handling equipment for a given purpose. He thought professional engineers could perform a great service if they could show the means available for handling materials.

Mr. Coes illustrated his remarks with a series of lantern slides, showing the evolution of such familiar apparatus as the portable belt conveyor, the stevedore truck, etc., and including practically all of the present methods of mechanical handling.

Mr. Coes predicted that mechanical handling of materials would be extended considerably within the next few years, and that problems now outstanding would be solved. It is the duty of engineers who lay out plants to insist at the start that designs provide for proper handling of materials.

Discussion

Mr. J. A. Shepard[1] agreed with the author's statement that "modern civilization is the direct result of the application of the principles of the sub-division of labor." He pointed out, however, that each sub-division of labor introduces an intermediate materials-handling problem which, if not properly solved, partially neutralizes the undoubted advantages of the sub-division. "Handling 168 tons of materials per ton of finished castings" summarizes the problem as it affects the foundrymen, but this statement gives no indication of the further problem of handling the casting through sub-divided finishing processes to wholesaler, retailer and finally consumer—rolling up a grand total of materials handling. Yet this is the situation concerning practically every commodity before it reaches the ultimate consumer. Mr. Shepard enunciated the following principle:

At the Materials Handling Session

Left to right, back row: W. N. Dickinson, M. F. Lawrence, R. H. McLean, H. E. Whitaker; front row: F. A. Wardenberg, H. V. Coes, R. M. Gates, N. C. Johnson, K. Dodge.

> "Owing to the great number of relatively simple handling operations entailed by the sub-division of labor, efficient handling, together with a low capital cost for handling equipment, is likely only through the choice of a type of handling machinery capable of the greatest possible flexibility and mobility, thus enabling each unit of handling machinery to perform the maximum number and variety of handling operations.
>
> "Moreover, the extent to which any type of handling equipment will occupy building or yard room which would otherwise be available for production processes, must necessarily become an important factor in making a choice."

Sam L. Libby,[2] following Mr. Shepard, criticized the manufacturers of materials-handling equipment whose attitude, he said, had been to sell as much of their machinery as possible. He thought one of the best things the Materials Handling Division could do would be to bring all the manufacturers to agree in a broad viewpoint of the problem.

H. M. Lane[1] emphasized, first, the need for coöperation, between the material handling people of radically different classes so as to get the right equipment for a given set of conditions; and second, the importance of the coöperation of the architect, without whom the plans of the materials handling man could easily be set at naught.

W. N. Dickinson, R. H. McLean, J. G. Hadfield, M. F. Lawrence, Wm. F. Hunt, and W. C. Brinton, also contributed to the discussion, and all agreed that the problem upon which Mr. Coes had concentrated attention was worthy of further consideration and detailed study by the Materials Handling Division of the Society.

Students Conduct Important Session

Under the auspices of the Committee on Relations with Colleges and under the direct supervision of Dr. H. G. Tyler of this committee, the members of the Student Branches of the Society conducted a session on Thursday morning. An innovation in the meeting activities of the Society and in its relations with students, this session considered two technical papers and a statement of the problems of Student Branch operation in a manner equal to if not better than some of the sessions conducted by mature members of the Society.

Before the session opened, prominent members of the Society and the profession mingled with the students and explained the ideals of the Society and its scope of activities.

Dr. W. H. Kenerson, newly elected chairman of the Committee on Relations with Colleges, presided at the formal presentation of the following papers: Draft-Tube Design with Reference to the Hydraucone by W. K. Ramsay of M. I. T.; and Flow of Water in Hydraulic-Turbine Draft Tubes by George E. Lyon of R. P. I. Both papers were presented by the authors. They will appear in a later issue of Mechanical engineering with the pertinent discussion.

The balance of the three hours devoted to this session was given over to a discussion of the problems of Student Branch organization and operations. J. M. Spitzglass of Chicago told of the successful methods used at the Armour Institute Student Branch.

Over two hundred students attended and while the representation of New York schools was high, there were still a great many from outside, some coming from Atlanta, New Orleans, Pasadena and Cincinnati.

Conference on Research

A better interchange of scientific and research information through the agency of the Engineering Division of the National Research Council is within reach if the ideas developed at the Research Conference of the Annual Meeting and transmitted to Mr. A. D. Flinn, vice-chairman of the Division, who was present, are carried out.

This conference, held Thursday, December 8, was conducted by Prof. A. M. Greene, Jr., chairman of the Society's Research Committee, and the attendance of over forty included many authorities on engineering research. Two sessions were held, culminating in the organization of an Advisory Committee to help the National Research Council in the correlation of research data as well as to make suggestions to hasten the completion of the Council's scheme.

It was generally conceded that publicity would be the most effective method of eliminating waste in research, caused chiefly by duplication of effort, by lack of a coördinated and coöperative research program and by failure to adequately define the research problem before inaugurating experimental work.

To circumscribe the discussion somewhat and to confine it to the Annual Meeting topic—elimination of waste—four items were scheduled on the program, two being technical papers and two reports of committees. The papers were Elimination of Waste in Industry through Research, by F. A. Wardenburg,[2] and Research in Leather Manufacture, by Arthur W. Thomas;[3] the re-

---

[1] Pres., Lane & Bodley Co., Cincinnati, Ohio. Mem.Am.Soc.M.E.

[2] Asst. Ch. Engr., E. I. duPont de Nemours & Co., Wilmington, Del.

[3] Professor Food Chemistry, Columbia University, New York, N. Y.

ports were those of the Sub-Committee on Lubrication and of the Sub-Committee on Steam Table Research. Messrs. Wardenburg and Thomas presented their papers in person. The lubrication report was presented by Mr. Albert Kingsbury, Kingsbury Machine Works, Philadelphia, chairman of the committee, and the steam table report by Mr. George A. Orrok, consulting engineer, New York, and by Dr. H. N. Davis, Harvard Engineering School, who is conducting a portion of the steam-table research.

Mr. Wardenburg detailed the possibilities of research work in the reduction of manufacturing costs, citing several examples in the war which had resulted in the saving of millions of dollars. He then described a plan for conducting commercial research work under the commercial incentive, and secondly a suggested coöperative plan for conducting general research work. As an element of the latter he suggested the collection of a large fund for research to be placed under the jurisdiction of some central body, like the Research Committee of this Society, which would plan and carry out the research program.

Mr. Thomas then presented his paper on research in leather manufacture, concluding with the significant statement that though leather had been in use for many centuries, we are only just beginning to find out the elementary chemistry of the reactions involved in its manufacture. He quoted this as an example of the magnitude of the general research problem in the industries.

The question of duplication of research was discussed considerably at the meeting; but when the ideas of all the speakers were brought out, the impression was left that though almost every problem is being investigated by more than one agency, the phases are all different and each investigation practically constitutes a separate piece of work. Mr. Flinn described how the "card-index" of the National Research Council would furnish an excellent means of posting everyone on what everyone else was doing.

In presenting the progress report of the Sub-Committee on Lubrication, Mr. Kingsbury pointed out the inherent difficulties in undertaking any measurements in a film of lubricant within a few thousandths of an inch of space. He described the experimental work of the committee in the field of increase of pressure on lubricants. He illustrated his remarks by means of curves prepared by Mr. Mayo D. Hersey, professor at Massachusetts Institute of Technology, Department of Physics, who was doing the experimental work.

In connection with the steam-table research Dr. Davis said that he felt "very hopeful" that his organization would soon be able to get something on the Joule-Thomson effect, which was his assignment in this research. Dr. S. W. Stratton, director of the U. S. Bureau of Standards, supplemented Dr. Davis by telling just where the Bureau stood in its part of the investigation, and Mr. Orrok closed by reporting how the money was coming in, stating that the prospects were very bright for the collection of the seventy or eighty thousand dollars necessary, and for the completion within three years of this very necessary extension of the upper limit of the steam tables.

Among other prominent speakers at the session were Prof. H. F. Moore, of the University of Illinois, who is in charge of the important research on Fatigue of Metals being conducted with the assistance of Engineering Foundation; Dean Anderson, in charge of the research program of the American Society of Heating and Ventilating Engineers; H. C. Dickinson, research director of the Society of Automotive Engineers; and Prof. P. C. Walker, dean of the Engineering School of the University of Kansas.

Professional Engineering Education for the Industries

The Society for the Promotion of Engineering Education joined Thursday afternoon with the A.S.M.E. in a session of three papers on the relations between engineering education and the industries as follow:

Professional Engineering Education for the Industries, F. C. Pratt,
A National Policy on Engineering Education, A. G. Christie,
College Education as Related to Industry, J. E. Otterson,

Professor Charles F. Scott, President of the S.P.E.E. presided. The three papers with the ensuing discussion opened by Dean Dexter S. Kimball are published on the first pages of this issue.

Credit is due Professor Dugald C. Jackson who arranged the program which attracted large attendance and developed exceedingly interesting discussion.

Stresses in Flat Cylinder Heads

The able paper by Major Gilbert Dudley Fish on Stresses and Deformation in Flat Circular Cylinder Heads was presented on Thursday afternoon at the first General Session of the Annual Meeting. Professor Robert H. Fernald presided.

Major Fish's paper was a mathematical analysis of form and loading of elastic disks where the thickness is uniform and where all strains are within the limits of true elasticity. Although of great value, the paper was highly specialized in its contents and the discussion could be entered into only by those who had actually attacked similar problems. An abstract of the paper with a résumé of the discussion presented will appear in a later issue of Mechanical Engineering.

Motion Pictures of Combustion

On Thursday afternoon R. Sanford Riley of Worcester, Mass., presented moving pictures showing actual conditions in a stoker-fired furnace. The great interest aroused in this exhibition made its repetition necessary. There was universal comment as to the value that these pictures will render in the development of a science of furnace combustion and in a later issue of Mechanical Engineering there will appear an account of the preliminary work done by Mr. Riley in determining the successful methods of preparing the motion pictures.

Motion Pictures of Handling Materials

Following out the custom inaugurated at the Spring Meeting the Materials Handling Division enjoyed an exhibition of motion pictures which showed the development of apparatus for handling coal and lime stone by machinery. These pictures, displayed by the Robbins Conveying Belt Company, were shown in place of the usual excursion.

Second General Session

The Second General Session of the meeting was held Friday morning with Dr. D. S. Jacobus in the chair. Of the three papers presented, one by Paul A. Bancel on Steam Condensing Plants appeared in the November issue of Mechanical Engineering. The paper by F. W. Dean on Testing Emergency Fleet Boilers using oil fuel will appear in the February issue of Mechanical Engineering and the paper on the Vertical Triple Expansion Pumping Engine by L. A. Quayle and E. H. Brown will appear in the March issue. The discussions pertaining to each of these two papers will appear with them. The present account will therefore only include the discussion on Mr. Bancel's paper.

In a written discussion, Professor A. G. Christie complimented the author on the presentation of new ideas on condenser operation and design, especially of the air cooler. He asked for additional information about the causes and nature of tube corrosion and for data on water velocity, on pressure loss through a single-pass condenser with high water velocity, and on methods of obtaining higher heat transfer through the tube surface.

D. K. Dean,[1] in a written discussion, combatted Mr. Bancel's statements regarding the tube layouts in which steam lanes are used to assist steam distribution, on the ground that there was lack of test evidence in the paper. He stated that the Bancel design is deficient in that it is difficult to distribute the steam equably to the ends of the condenser. Mr. Dean also made a detailed comparison of water temperature distribution in a double-pass condenser with the distribution in the single-pass condenser advocated by Mr. Bancel. He showed that the single-pass condenser gives a poor division of work along the tube length. He further pointed out that the ratio of cooling surface to the amount of steam condensed is well established and requires the use of two passes to utilize commercial tube sizes.

---

[1] 88 Broad St., Boston, Mass.

Mr. John F. Grace[1] criticized Mr. Bancel's use of a small tube, single-pass condenser with a high water velocity through the tubes on the grounds that small tubes clog and require high-power circulating pumps. He deemed it wise to use a moderate velocity and to clean the tubes occasionally. He stated that it was his experience that tube losses increase as the tube surface is decreased.

A written discussion by Mr. P. E. Reynolds[2] reviewed developments in condenser design which have followed a seemingly aimless path. He stated his belief that the design of Mr. Bancel permitted heat transfer in an atmosphere of pure steam. He regretted the lack of data about this feature. Mr. Reynolds touched on the relative merits of single- and double-pass condensers and pointed out that the double-pass type gives equal distribution of condensation over the tubes.

Mr. E. B. Ricketts[3] decried the lack of test data on the heat transfer in this type of condenser.

At the end of the discussion, Mr. Bancel promised to answer the questions in a written closure.

Aeronautic Session

Joseph A. Steinmetz, Chairman of the Aeronautic Division, opened the Aeronautic Session on Friday morning with an optimistic word for the future of aviation and for the future of the work of the Division in assisting the development of aviation especially for commerce. He then turned the meeting over to Professor E. P. Warner, Chairman of the Aeronautic Papers Committee who took the chair. In his opening remarks, Professor Warner explained the principal purpose of the Aeronautic Division to be the dissemination of facts regarding aerial transport.

The titles and authors of the papers presented at this session were as follows: Commercial Operations of Airplanes, by L. B. Lent, Air Lines and Some of Their Problems, by R. B. C. Noorduyn, Study of the Elastic Properties of Small-Size Wire Cable, by R. R. Moore, Tests of Plywood Webs With Lightening Holes Arranged as in Airplane Ribs, by D. T. Brown and R. J. Diefenbach.

The paper by Major Lent appears in another column of this issue. The other papers will appear in a later issue accompanied by the discussion relating to them.

Major Lent's paper presents data of great value to the problems of commercial aviation and with Mr. Noorduyn's paper, it incited discussion that indicated great possibilities in commercial aviation in the immediate future. In closing the discussion, Major Lent emphasized the seemingly important point that the aeroplane offered greater commercial possibilities as a freight express or mail carrier than in transportation of passengers.

Lieutenant E. E. Aldrin, Secretary of the Division, newly arrived from a trip abroad was at the meeting and he gave some interesting first-hand information relative to commercial flying in Europe.

Textile Waste Session

Mr. Charles T. Plunkett, Chairman of the Textile Division presided over this Session on Friday morning at which the Textile Division presented a program dealing with wastes in the textile industry. The papers on Hidden Wastes in Textile Plants by T. P. Gates and Economy in Textile Drying by B. R. Andrews will appear with their discussion in the March issue of Mechanical Engineering.

Charles T. Main opened the meeting with a report of the World Cotton Conference held in England last summer which he attended as a delegate of the Textile Division of the A.S.M.E. Mr. Main emphasized the fact that the British cotton manufacturers have joined in contributing about one million dollars for cotton research work. They have planned a large laboratory and they expect to take up the problems bearing on the manufacturing and finishing of cotton. Mr. Main spoke also of the movement on foot in this country to unite all bodies engaged in textile-research work in coöperation with the International Cotton Research Committee. The Cotton Conference itself impressed Mr. Main by the opportunity it offered for men from widely separated parts of the world to come together and partake of the wealth of information offered at the formal meetings of the conference and informally in the social gatherings.

Ordnance Session

The first session of the Ordnance Division held at an Annual Meeting of the Society was called to order on Friday morning by Waldo H. Marshall, Chairman of the Division. General Guy E. Tripp, Chairman of the Board of the Westinghouse Electric and Manufacturing Company, made the opening address in which he emphasized the responsibilities of the Ordnance Division and all those who have had experience in the production of ordnance material in the development of an organization to supplement the permanent staff of the Ordnance Department.

The principal paper of the session was delivered by Colonel J. W. Joyes, Chief of the Technical Staff, Ordnance Department, U. S. A. Colonel Joyes discussed the conditions in the past in the Ordnance Department and present indications of an effort to practice economy and save money. He discussed the limitations of tolerance in ordnance material which were somewhat troublesome during the war and indicated that the present effort is to study carefully the producability of the various articles of ordnance. The coöperative work between the army and navy in matters of design of ordnance was briefly reviewed. The showing was very satisfactory and duplications and wastes of effort in design are generally being avoided. The development of the Ordnance Department organization to prevent waste in overlapping was also explained by the speaker. He closed his address with an explanation of the policy of the Ordnance Department in investigating the possibilities of commercial articles before taking the design for strictly military uses.

Chairmen of the Sub-Committees of the Annual Meeting

Left to right, back row: G. R. Tuska, *President's Reception;* J. I. Lyle, *Informal Get-Together;* L. B. McMillan, *General Chairman;* W. S. Bowen, *Information;* H. D. Edwards, *Excursions;* Mrs. F. T. Chapman, *Ladies' Tea;* Mrs. Nixon Lee, *Ladies Acquaintanship;* Miss Burtie Haar, *Ladies Excursions;* E. Van Winkle, *Dinner Dance.*

Discussion at the session was contributed by Frank B. Gilbreth, Carl G. Barth, Fred J. Miller, F. G. Spencer, Captain Kimberly, R. D. Coleman, H. C. Spaulding and E. L. Sherwood who contributed problems relating to the design, specifications and manufacture of ordnance material.

Heat Balance of the Connors Creek Plant of The Detroit Edison Company

By C. HAROLD BERRY,[1] and F. E. MORETON,[2] DETROIT, MICH.

THE term "heat balance" is currently used in two different senses. At times we speak of the heat balance when we mean a physical condition in the plant whereby there is a balance of certain heat-absorbing and heat-developing capacities. Again, by heat balance we mean a thermal balance sheet which records the ultimate disposition of all the heat developed from the fuel used.

This paper discusses the heat balance in both senses for the Connors Creek Plant of The Detroit Edison Company. We shall first describe briefly the apparatus in the plant, following this by a discussion of the ideal operating conditions, and finally presenting actual results. The plant is considered just as it stands, without reference to changes now under consideration or construction.

Description of Equipment

The main turbo-generators are six in number—three[3] of 20,000 kw. capacity, one of 30,000 kw. capacity, and two of 45,000 kw. capacity, giving a total installed capacity of 180,000 kw.[4] The turbines are served by fourteen boilers, each of 2365 boiler hp. builder's nominal rating.

The boiler-feed pumps are steam-turbine-driven, with the exception of one which is motor-driven. One general-service water pump is steam-turbine-driven. All other plant auxiliaries are motor-driven, some by alternating-current motors, some by direct-current motors, the choice depending upon the nature of the driven unit. As it works out, those auxiliaries whose uninterrupted running is essential to plant operation are all driven by direct-current motors, while auxiliaries whose stoppage does not immediately affect the rest of the plant are driven by alternating-current motors. This division is not due to any belief in the superior reliability of direct-current motors, but is due to the fact that most, if not all, of the essential auxiliaries are of such character as to require or benefit from widely variable speed. Such are stokers, blowers, hot-well pumps, dry-vacuum pumps, circulating pumps,[5] etc.

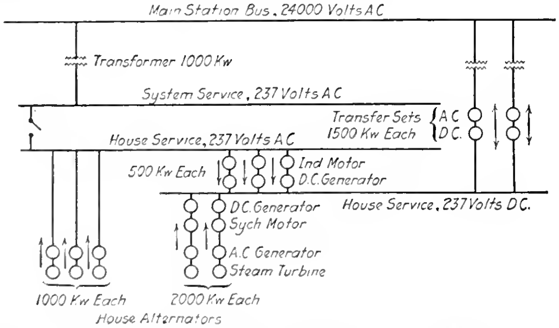

Fig. 1 Arrangement of Auxiliary Electrical System, Connors Creek Plant

The arrangement of the auxiliary electrical system is shown in Fig. 1. Alternating current for auxiliaries is available from either of two buses: (*a*) The "system service" bus, which is fed through a transformer from the main station bus, or (*b*) the "house service" bus, which is fed by three 1000-kw. turbo-generators. A tie switch is provided whereby these two buses can be connected. When this tie switch is closed, such of the 1000-kw. house alternators as are running must perforce operate in parallel with the main units. When this is done (and it is common practice at Connors Creek), the governors of the small units are set for a speed slightly above system frequency, and the house units are operated on the hand throttle, with constant steam flow and virtually constant load.

Direct current is available from a single bus (actually constructed as a ring). Owing to the importance of continuous service from the motors connected to this bus, it is fed from four sources:

a Two 1500-kw. steam-driven direct-current generators. Each of these consists of a turbo-alternator permanently connected (by bolted links) to a synchronous motor-direct-current generator set, so that the combination is merely a steam-driven direct-current generator with an electrical speed reduction instead of gears.

b Three 500-kw. motor-generator sets (induction motors) driven from the house-service alternating-current bus.

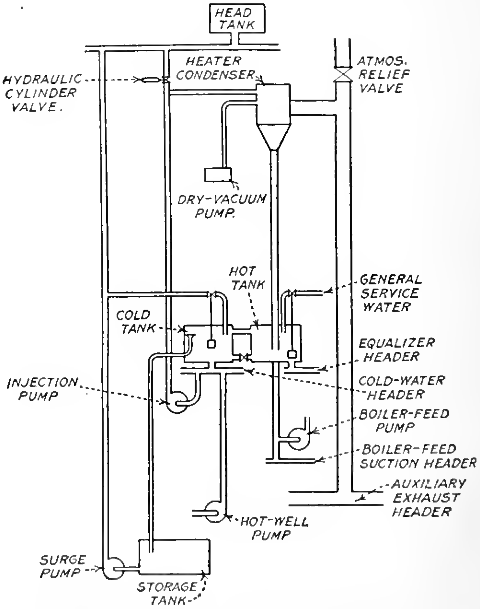

Fig. 2 Arrangement of Auxiliary Exhaust-Steam and Feedwater Heating Apparatus, Connors Creek Plant

c Two 1500-kw. motor-generator sets (synchronous motors) driven from the main station bus. These sets have characteristics and controls such that they may deliver power in either direction, wherefore they are known as "transfer sets."

d A storage battery of 1500 amp-hr. capacity.

An important characteristic of a system of this sort is that the load on the auxiliary steam turbines is independent of the auxiliary power demand of the station. With the tie switch closed between the system service and house-service buses, and with the transfer sets operating between the main system and the house-service direct-current bus, the house-turbine loads may be adjusted at will, within limits set by the capacities of the apparatus.

The function of the house turbines is twofold:

a To furnish a standby source of power for station auxiliaries in the event of a system failure, and

b To furnish exhaust steam for boiler-feedwater heating.

Fig. 2 shows the arrangement of the auxiliary exhaust-steam

[2] The Detroit Edison Company.

[3] At the present writing one of these is in the manufacturer's plant in the course of rebuilding. A 10,000-kw. unit stands in its place.

[4] For the time being 170,000 kw.

[5] At the time of writing, the older of these pumps still have induction motors, which are to be displaced by direct-current motors.

Abstract of the fourth of a group of papers presented at the Power Waste Session of the Annual Meeting, New York, December, 1921, of The American Society of Mechanical Engineers. The other three papers appeared in the December, 1921, issue of Mechanical Engineering, pp. 790–795.

and feedwater-heating apparatus. The auxiliary exhaust heater receives the exhaust steam from five house turbines, from six boiler-feed-pump turbines, and from one general-service-pump turbine, as well as the vapor formed in the boiler-feed make-up evaporators. This steam passes upward into five barometric-condenser heads, where it meets condensate from the main condensers. The resulting hot water is discharged into the hot boiler-feed tanks, whence it is pumped into the boilers. The cold condensate piping and tanks are designed to care for variations in the volume of water in the boilers at times of variable plant load, and to safeguard the boiler-feed pumps against failure of the supply. Inasmuch as these barometric condensers serve as condensers for the auxiliary system and as feedwater heaters for the main system, they are known as "heater condensers."

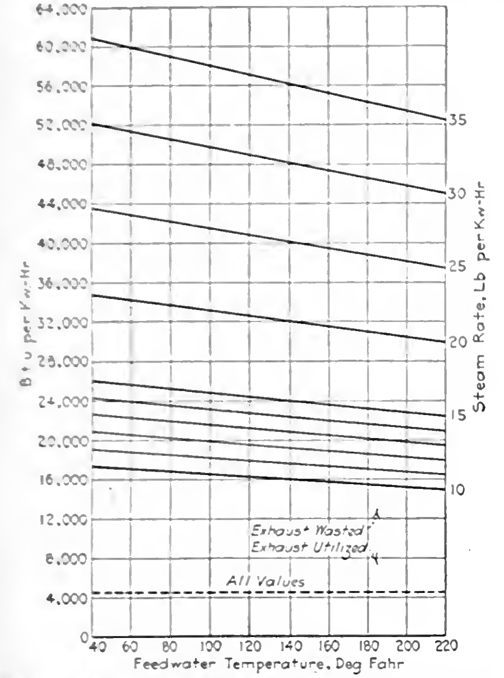

Fig. 3 Computed Cost of Power for Variable Turbine Steam Consumption and Boiler-Feed Temperature, with Fixed Initial Steam Conditions

(Steam pressure, 240 lb. per. sq. in. abs.; superheat, 200 deg. fahr.; boiler-room efficiency, 0.75.)

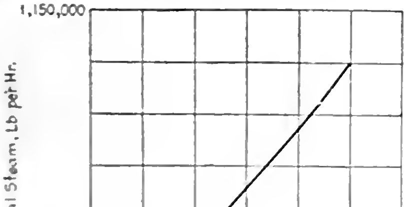

Fig. 4 Total-Steam Curve of Main Unit

Theory of Operation

There are two viewpoints from which to state the gain in station economy due to the operation of a system of this kind:

a A simple but approximate view—the substitution of cheap power for costly power

b A complicated but exact computation—a saving due to increased feedwater temperature, offset by an increased station steam consumption.

The matter will be discussed from each of these two points of view.

In the chart shown in Fig. 3 the full lines show the computed cost of power for variable turbine steam consumption and boiler-feed temperature, with fixed initial steam conditions. If we assume that all losses in the turbine appear as heat available from the exhaust steam, that is, if we neglect radiation losses, and if we recover usefully and credit to the turbine all of the heat available from the exhaust steam, then the cost of power is constant for all conditions, and is equal to the heat equivalent of a kilowatt-hour (3415 B.t.u.) corrected only for boiler-room losses. For the assumed boiler-room efficiency of 0.75, this gives us a cost of power of 4550 B.t.u. per kw-hr., and this is shown plotted in Fig. 3 as a dashed line.

In the case of a plant like Connors Creek, the main units have a steam consumption of, let us say, 12 lb. per kw-hr., wherefore power generated by them costs from 18,000 to 21,000 B.t.u. per kw-hr. The house turbine, whose exhaust heat we may assume to be fully utilized, produces power at a cost of 4550 B.t.u. per kw-hr. Clearly, the displacement of a portion of the power generated by the main units at high cost by power generated by the house turbine at much lower cost will result in a gain in station economy. From this it would appear that the maximum house-turbine output is to be striven for. But the matter is not so simple, for here we meet the outstanding feature of the system—the auxiliary exhaust pressure may be adjusted to any value between the lowest attainable absolute pressure and atmospheric pressure. If we operate at a very low pressure, the auxiliary exhaust steam, and therefore the boiler feedwater, are at low temperature, with a resulting high cost of power from the main units. Further, with a small temperature rise of the boiler feedwater, very little exhaust steam can be condensed, wherefore the output of the house turbine is small. As the auxiliary exhaust pressure rises, the boiler-feed temperature rises, lowering the cost of power from the main units, and at the same time the heat absorption of the boiler feedwater increases, condensing more auxiliary exhaust steam and permitting the generation of more cheap power by the house turbine. As the auxiliary exhaust pressure continues to rise, however, another influence enters: the steam consumption of the house turbine increases, that is, the power output of a given steam flow will be less. This reduces the proportion of cheap power generated, and eventually a point is reached at which an increase of auxiliary exhaust pressure will decrease the station economy. Our problem is to locate this point of maximum station economy. It will be worked out in the more exact analysis which follows.

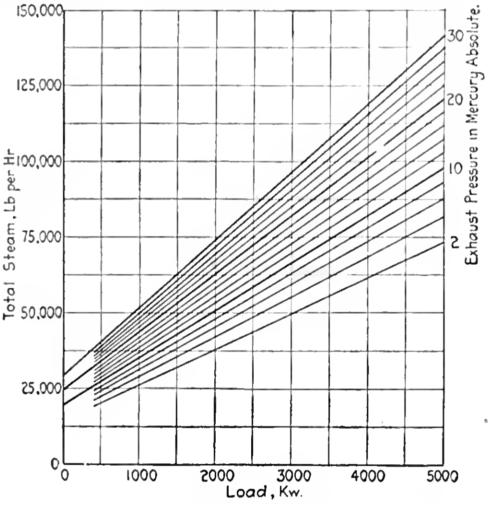

Fig. 5 Total-Steam Curves of House Turbine

As is pointed out below, in discussing the results of this study, a complete analysis of this problem requires a large fund of infor-

mation, which unfortunately is not yet available for the Connors Creek plant. We shall therefore carry out this study for an assumed plant with characteristics consistent with the performance of Connors Creek. The results obtained will serve to define the problem rather than to present a solution for the actual plant. The following data are assumed:

Total station load, including auxiliary power demands, constant and equal to 100,000 kw.
Main unit steam consumption assumed to conform to the total-steam curve of Fig. 4
A house turbine of 5000-kw. capacity, whose performance is shown by the total-steam curves of Fig. 5[1]
Initial specific total heat of steam at 225 lb. per sq. in. gage and 200 deg. superheat = 1313 B.t.u. per lb.
Temperature of condensate leaving main unit condensers = 70 deg. fahr.
Boiler feedwater leaves the heater condensers at a temperature 10 deg. fahr. below the boiling point corresponding to the auxiliary exhaust pressure
Boiler-room efficiency equal to 0.75
Radiation neglected.

Our first step is to develop a very interesting relation which applies to any steam prime mover whose exhaust is wholly used for heating water. If the water is heated from a constant initial temperature to a constant number of degrees below the boiling point corresponding to the exhaust pressure, then a curve plotted between the turbine load and the quantity of water capable of being heated will have the same shape as the curve plotted between turbine load and total steam. Proof of this fact is given in one of the appendices of the complete paper, where the relations involved for the conditions assumed above are developed. For these conditions the curves of Fig. 6 have been prepared.

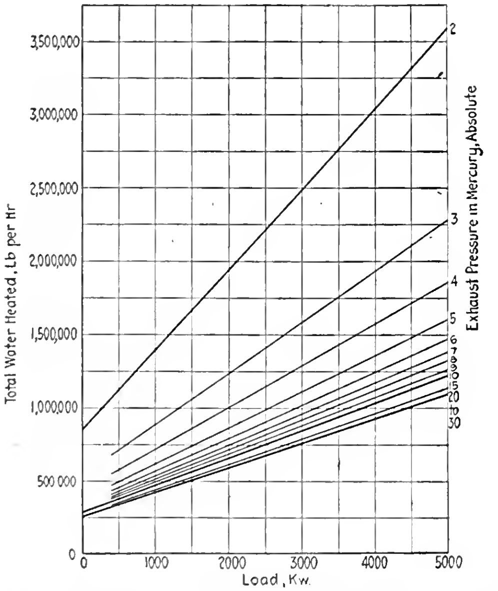

Fig. 6 Water Heatable by Exhaust Steam from House Turbine

We are now in a position to determine the cost of power for variable house-turbine load. Another appendix of the complete paper indicates the method and gives the computations in detail. The principal results are shown in Figs. 7 and 8. From the curves it is clear that the best station economy is obtained with a house-turbine load of 4500 kw. and a boiler-feed temperature of 160 deg. fahr. In Fig. 7 the small circles at zero house-turbine load indicate conditions with the house turbine shut down.

In interpreting these results, attention must be directed to the fact that the curve of cost of power is rather flat. Operation at a condition somewhat removed from the best point results in only a small increase in the cost of power. However, modern power-plant operation is largely concerned with small increments, and a gain of even 100 B.t.u. per kw-hr. is not to be neglected.

Attention must further be called to the fact that the computations here given are based on one set of assumed conditions. To carry out this study in general would require much detailed information. We should need the total-steam curve for the main units running in various combinations over the entire range of plant load. We should also need the total-steam curves for all house turbines (at Connors Creek, five house alternators, six boiler-feed pumps, one general-service pump—twelve turbines in all) over their entire range of load and exhaust pressure. We should then have to develop combined curves for various load distributions among these auxiliaries, and for each of these we should have to compute results for various plant loads and main unit distributions, for various values of the condensate temperature and for various values of the interval *d* by which the boiler-feed temperature is below the boiling point corresponding to the auxiliary exhaust pressure. This is obviously a large undertaking, and one for which we have not yet secured adequate data.

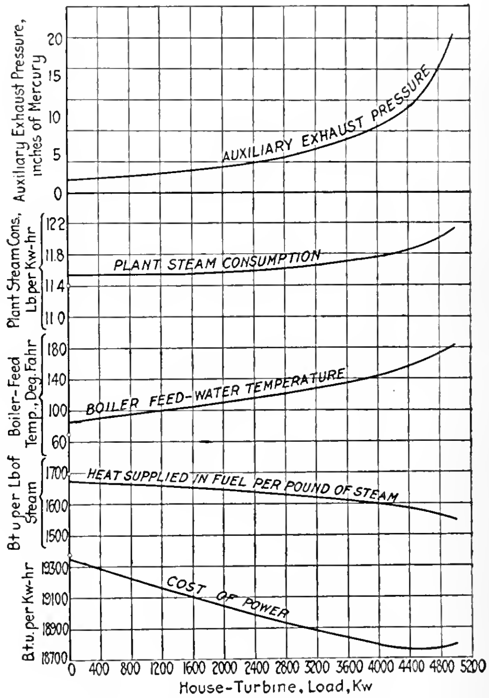

Fig. 7 Cost of Power for Variable House-Turbine Load

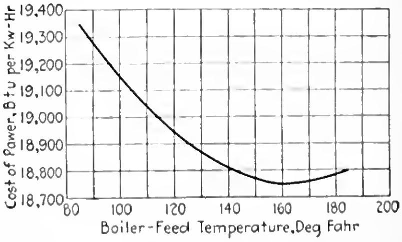

Fig. 8 Variation of Cost of Power with Boiler-Feed Temperature

The main facts, however, are clear. For a system of this type there is a best point, and it is just as wasteful to heat the feedwater to a higher temperature as to a lower. We believe that for the Connors Creek plant the best economy is obtained with a boiler-

---

[1] These curves are based on an actual test of a 1000-kw. set, and probably indicate a higher steam consumption than is normal for a 5000-kw. unit.

TABLE 1 THERMAL BALANCE SHEET FOR APRIL 1921, THE DETROIT EDISON CO., CONNORS CREEK POWER HOUSE

The month of April, 1921, represents neither the best nor the current plant performance. At that time the plant was still operating with crippled units and with much equipment still in progress of recovery from post-war conditions.

feed temperature lying between 160 and 180 deg. fahr., and in this range we try to operate.

Balance Sheet

The preparation of the accompanying balance sheet, Table 1, calls for the exercise of considerable judgment in selecting data, and even for some "directed guessing." The major items are, of course, taken from direct observations, but such things as radiation and drip losses are not susceptible of measurement by practical means, and must be estimated on the basis of other observed data or simply on general considerations.

DISCUSSION OF THE POWER WASTE SESSION

The Power Division held a session on Tuesday morning, December 6, devoted to the subject of power waste. Prof. A. G. Christie, Johns Hopkins University, presided at the meeting. Papers were presented as follows: Auxiliary System and Heat Balance at the Delaware Station of the Philadelphia Electric Company, by E. L. Hopping; Heat Balance of Colfax Station, by C. W. E. Clarke; Heat Balance System for Hell Gate Station, by J. H. Lawrence and W. M. Keenan; and Heat Balance of the Connors Creek Plant.

of the Detroit Edison Company, by D. Harold Berry and F. E. Moreton. The meeting was then thrown open to a discussion of the general subject of heat balance.

Prof. Arthur M. Greene, Jr.,[1] read a written discussion by John A. Stevens[2] in which he criticised the four plants discussed in the papers for operating at such low pressures and temperatures. He called attention to the recommendation in the report of the Superpower Survey of a pressure at the throttle of 300 lb. per sq. in. and a superheat of 230 deg. fahr., and submitted figures of the pressures and temperatures of important steam plants of this country, England and Europe. He expressed a belief that American engineers were following rather than leading English and French engineers in the development and use of high-pressure steam.

J. R. McDermet[3] read a written discussion of Mr. Hopping's paper with special reference to the proposed air extractors mentioned by the author. Mr. McDermet divided systems of driving central-station auxiliary apparatus into three groups, (1) by steam, (2), by house turbine with electric distribution and (3), by extraction heating. He said that it was possible by rather complicated mathematics to show that with an infinite number of extraction heaters following the turbine expansion, the power-station cycle reduces from the Rankin to the Carnot. While from practical considerations this infinite number of heaters is impossible, the extraction heater method has certain advantages which, he pointed out, made it an attractive method of obtaining heat balance.

The value which Mr. Hopping gave to vent loss from the heater appeared to Mr. McDermet to be roughly correct although possibly too low. The installation of air extractors as proposed in the Delaware Station has three advantages: first, elimination of vent loss heat in the operation of the heater which in the proposed installation should be reduced to approximately 0.5 per cent instead of 5 per cent; second, the loss of water through the heater vent in the form of steam will also be eliminated; and third, the reduction of temperature of feed from 210 to 140 deg. will give an added economizer effect and probably increase the boiler efficiency about one per cent. The air extractor which should be used operates upon the Elliot system of explosive boiling.

James M. Taggart,[4] in commenting on Mr. Hopping's paper, said it would be of interest to know the amount of increase in heat return realized by lowering the feedwater temperature to 140 deg. He also commended Mr. Berry's emphasis of the importance of speed control of auxiliaries. He considered that only a doubtful increase in reliability was being obtained at the Colfax Station by the use of turbine drive for forced draft fans and boiler feed pumps and that the sacrifice in economy was considerable.

John Anderson[5] asked why banking coal losses had not been included in Fig. 3 of Mr. Hopping's paper. He thought Mr. Hopping had used too high an economizer efficiency in view of the feedwater temperature of 210 deg. If pulverized coal had been used in the Delaware Plant a figure of 16,900 B.t.u. per net kw-hr. might have been obtained instead of the 17,982 B.t.u. actually obtained.

N. E. Funk[6] suggested that the Society standardize heat balance as it had standardized boiler testing, pointing out that in the papers presented three different methods had been used in presenting heat balances so that comparisons were difficult. He did not wish the impression carried away that the Philadelphia Electric Company was averse to electric drive for auxiliaries. He thought that automatic control appratus which could be started and stopped by push buttons was entirely satisfactory and would relieve operators of any except the most simple duties.

Mr. Funk was not in accord with the trend toward higher temperatures and pressures unless they were necessary in reducing the actual cost of producing current. The cost involved in operating under high boiler pressures and temperatures must be figured when any theoretical saving due to these changes is proposed.

Leo Loeb[7] spoke of the considerations involved in selecting drive for station auxiliaries and presented a summarized heat balance covering a week's operation at the Delaware Station.

Francis Hodgkinson[8] spoke of the delusion under which engineers had formerly labored that so long as steam from auxiliaries was condensed in the feedwater heater the water rate of these auxiliaries did not matter. Nine or ten years ago he had devised a series of valves for accomplishing heat balance which provided for bleeding the main turbine at a time of least efficiency in heating feedwater and supplying steam to the turbine when the reverse condition existed. One reason for leaning toward the electric drive was the elimination of undesirable conditions in the basement containing steam-driven auxiliaries. He thought that engineers generally were favoring the house turbine heat-balance scheme.

H. R. Summerhayes[9] also spoke of the necessity of having steam-driven auxiliaries of the highest economy if economy of the main unit is desired.

R. J. S. Pigott[10] pointed out the fact that the heat consumption of a plant varies with the load and that in order to determine the most economical combination of auxiliaries it is necessary to study more than one load. One system for obtaining heat balance might be the best for a given load while another system might be the best for a variety of loads.

L. P. Breckenridge[11] said that he was impressed with the desirability of serving industrial areas by power plants in which the heat energy of the coal could be converted into electric energy in the most economical way and called attention to the report of the Superpower Survey.[12]

T. E. Keating[13] spoke of the most economical boiler feed temperature which, he said, should be between 160 and 170 deg. if economizers are used.

Joseph Pope[14] said that the duplex drive offered difficulties in shifting load from the steam to the electric ends. He also spoke of the lack of speed control on large turbines at the auxiliary steam inlet connection which might result in overspeeding in case of a very light load on the turbines and a large supply of low pressure steam.

J. B. Scott[15] asked if the authors of the papers would install the systems of heat balance described by them in case the stations were to be redesigned.

George A. Orrok[16] spoke of the possibility of approaching the Carnot cycle in the power plant. He believed that the load factor at which the station was to run was the determining factor in choosing the auxiliaries to be used in working out a heat balance.

Closure

E. L. Hopping, in closing the discussion on his paper, and in answer to a question which had been asked about burning oil, said that the furnaces at the Delaware Station were designed so that, with few alterations, oil or pulverized fuel might be used in place of stoker-fired coal. In answer to Mr. Anderson, he pointed out that the figures given in the paper included the standby losses. He called Mr. Hodgkinson's attention to the cleanliness of the auxiliary basement at the Delaware Station where steam-driven auxiliaries are installed. As Mr. Piggott had advised, a complete study of economics at all loads was entered into in deciding upon the auxiliaries for this station. In designing a new station, the speaker said, he would use all of the experience gained at the present and other stations in making a choice of auxiliaries.

C. W. E. Clarke, in referring to Mr. Stevens' suggestion of using

Compounding the Combustion Engine

By ELMER A. SPERRY,[1] NEW YORK, N. Y.

To engineers versed in the problems of selecting and designing prime movers, the advantages of the compound combustion engine are readily apparent. It is light compared with the normal Diesel, being in special cases, according to the author, less than one-tenth, and in some instances less than one-twentieth, the weight for the same output. Its mechanical efficiency is extremely high, and a distinct gain in overall efficiency from fuel to shaft is said to have been made, as well as a very definite gain in simplicity, direct performance and smoothness of the crankshaft diagram. This has been achieved while adhering to the best practice, namely, four-cycle operation.

This paper presents the results of research by the author extending over a series of years, during which it is claimed that not only has the high-pressure principle been thoroughly established, but all the important requirements have been worked out, and finally an engine embodying practically all the advantages has been subjected to long continuous runs.

THE high-compression or Diesel cycle in combustion engines has worked nothing short of a revolution, having brought to the prime mover its choicest heritage, the highest thermodynamic efficiency known. The fuel economies of these engines have forced them to the front. They have become extremely reliable and easy to operate; instances are becoming common of long runs without overhaul—long-continued performance without shutdown or forced stop of any kind.

As experience is gained with these engines, however, there have developed some objectionable features which are serious. Though they occupy somewhat less space than boilers and engines, the weights of Diesels are on a par with, if not somewhat in excess of, those of reciprocating engines with their boilers and decidedly in excess of those of water-tube boilers and turbines. The standard product of the largest builder of Diesel engines for the merchant service weighs about 450 lb. per shaft horsepower and is large and bulky. A substantial increase in tonnage of freight carried is only one of the gains that would be secured, could these engines be made much lighter and smaller for the same power.

The weight is not the only difficulty with these large engines, however, for they cost more than steam equipment of equal power. One instance of $200,000 excess for a 3500-s.hp. ship is cited. In another ship for the same service and of the same power the weight was 60 per cent in excess of the turbine equipment and the cost 212 per cent, amounting to $306,000 excess. Notwithstanding this extra capital charge, the first ship at three-fourths capacity in the Far East trade can earn nearly double net (83 per cent) over its turbine competitor of the same power and construction and with its machinery weighing a third more than steam equipment.[2]

Again, it has been found that almost without exception a grade of fuel oil known as Diesel oil must be employed. This is a partially refined product costing upon the present market considerably more than bunker oil burned under the boilers.

The fuel-oil problem in itself renders some advance absolutely imperative. Conservation of our oil should be backed by Government enforcement to stop the prodigal waste which results from bulk or furnace firing of enormous quantities of these highly concentrated fuels, destroying three to five times the quantity, power for power, required by steam, especially now since the cheapest petroleum can yield to the full its wonderful store of energy in the most direct way possible by being burned drop by drop directly in the cylinder and practically at the point where the work is to be done.

COMPOUNDING AS A REMEDY FOR INHERENT DIFFICULTIES WITH DIESELS—THE AUTHOR'S EARLY WORK

In a report made by a group of engineers in 1900, it was stated that if the combustion engine could be successfully compounded, a most important gain would be made in its weight and size. The fact that compounding presents other advantages has been known to engineers for a number of years, but the difficulties have been looked upon as insurmountable.

A year ago Professor Watkinson, director of the important engineering laboratories of Liverpool University, in discussing an epoch-making paper by Engineer-Commander Hawkes on the Admiralty's extensive research on Diesels, stated, in substance, that we must recognize that the combustion engine in its present state was very crude and in compounding only lies the line along which the next great step in progress would be made. And he also stated that much greater results are bound to follow the compounding of combustion engines than were ever realized by compounding steam engines; first, because of the very much greater range of pressures available, and secondly, because the great enemy to compounding in steam, viz., condensation, is not present.

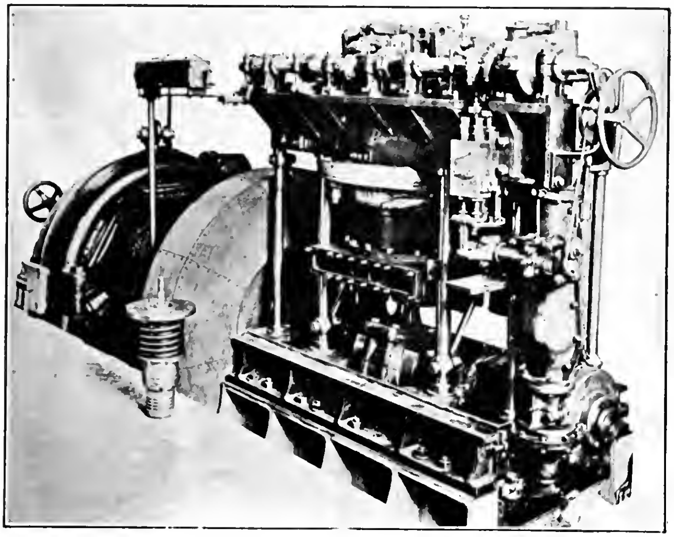

FIG. 1 10 : 1 MARINE-TYPE COMPOUND OIL ENGINE BUILT FOR HEAVY DUTY

Activity in this field is now prodigious and workers in various parts of the world are commencing to realize that a great advance step is imminent. In America, a group headed by the author has been engaged on this problem for upward of thirty years. Starting in 1890, his first compound was running before the World's Fair. The patent records give evidence of this early work under date of December 10, 1892. A number of engines have steadily followed each other, each involving improvements resulting from previous experience, until the essential problems have been conquered. Not only has the principle been thoroughly established, but all the important refinements have been worked out, and finally an engine embodying practically all the advances has been subjected to long continuous runs. Data almost invaluable to the art have been secured, together with a series of indicator cards and diagrams that exceed a thousand in number.

The outcome has been that the various prophecies of thoughtful engineers in the past have been more than fulfilled and there is every evidence that the heavy-duty compound combustion engine is everything that was hoped for. It is light compared with the normal Diesel, being in special cases less than one-tenth, and in some instances less than one-twentieth, in weight for the same out-

Abstract of a paper presented at the Annual Meeting, New York, December 5 to 9, 1921, of THE AMERICAN SOCIETY OF MECHANICAL ENGINEERS. All papers are subject to revision.

put. Its mechanical efficiency is extremely high and a distinct gain in overall efficiency from fuel to shaft has been made, as well as a very definite gain in simplicity, direct performance and smoothness of the crankshaft diagram. This has been achieved while adhering to the best practice, namely, four-cycle operation.

COMPOUNDS LIGHTER AND CHEAPER—MUCH LARGER UNITS POSSIBLE

The lightness and simplicity of the compound solves the capital-charge factor automatically. Engines of this type weighing only a fraction of the weight of the present Diesel will inevitably be found to be much less in first cost as well as in cost of upkeep.

Much higher powers than are now available are thought to be of extreme importance and much interest is centered upon the question; in fact, the more advanced among the Diesel builders are today concentrating upon ways and means to attain still higher powers from a single cylinder working on its present cycle. Of course this will increase instead of decrease the weight per horsepower. It is to the compound that we must look for a solution of this problem, for the reason that within present cylinder and cylinder-wall limitations, powers in excess of 10,000 hp. per engine are entirely practicable and are accompanied by all of the proportionate savings in weight, space and capital charge that have been pointed out.

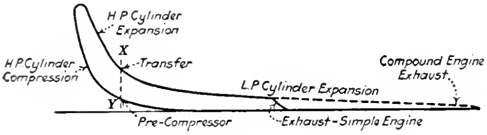

Fig. 2 Indicator Card of Diesel Engine

Our own Government has watched the progress of this work for a number of years, inspected the development in its various stages, and has come forward with orders for an initial engine which, together with orders from other sources, is now under construction. To illustrate to what low figures the compound principle can be relied upon to bring the heavy-oil engine, it should be stated that among these orders is one now under construction to weigh about five pounds to the brake horsepower. This may be looked upon as extreme, but the designed weights and finished parts as they now stand are below this figure. This brings us within striking distance of aviation engines, where the fire risk through the presence of gasoline and the electric ignition system constitutes one of the greatest menaces to aviation progress. The remarkably high mean effective pressures of the heavy-oil compound will give us the aviation engine and entirely eliminate both these sources of fire risk.

The reason for the great weight in all classes of Diesel engines is apparent when it is understood that they are designed around an extremely small quantity of air and oxygen at each stroke, an amount so minute as to be quite surprising when compared to the ponderous engine itself. The volume of the power gases available to do work is limited to the size of the combustion space, and when it is remembered that this is confined to a small crevice in the end of the cylinder of the order of one-twentieth of the travel of the piston, the limitation is at once seen. Attempts to make it larger produce both compression and ignition temperatures that are too low and we have semi-Diesel and surface-ignition engines confined to smaller sizes with tendencies to a lower grade of performance. Such engines are difficult to start and represent no gain in weight.

Two of these volumes are sometimes combined as in the opposed-piston Junkers engine. The size of the combustion space, though still minute, is known to give some small advantages over the regular engine which has only one-half of this space, but has the disadvantage in common with all two-cycle engines of the fractional piston-ring support practically without lubrication on the hot bridges as the exhaust port is uncovered by the piston.

SEPARATE CYLINDERS SUITED TO PRESSURE RANGES—TWO-STAGE COMPRESSION SECURES LARGE WORKING VOLUMES

Take, for instance, the Diesel indicator card, Fig. 2. Draw the vertical line XY and it is easy to see that the expansion pressures to the left are high and should do their work in a high-pressure cylinder, whereas those to the right, especially following the dotted extension line of expansion, are definitely low pressures and should do their work in a low-pressure cylinder suitable for the purpose. This is practically all that is attempted in compounding combustion engines. The vertical line XY also divides the compression curve into two stages, low and high, the latter taking place in the combustion cylinder proper as a second stage. No compressor delivering 500 or more pounds per square inch will undertake to do so in a single stage; there would be at least two stages. The old single-stage compression is discarded in the compound and this modern method of two-stage compression is adopted.

Supercharging or compressing in two stages gives the controlling advantage in that a very much larger unit volume of gases may be handled. The clearance spaces may be many times the size of those in the Diesel, and yet it is perfectly simple to bring these large volumes up to the requisite pressure and incandescent temperatures at the instant of fuel injection.

The large volume of power gases in the combustion chamber of the compound at once solves a number of important problems, makes the light engine easy of accomplishment, and overcomes a number of other difficulties at the same time. No longer is the chilled perimeter per unit volume of gas the controlling factor, as it is in the Diesel. The chilled walls are retired into the background as the large volume asserts itself, as compared with the small crevice indicating the total volume available in the normal Diesel (shown at C in Fig. 9), where the chilled areas exposed are very large and the volume very small. At a glance it will be seen that all this is reversed completely in the large dome-shaped clearance space D in Fig. 9, where the volume has increased very much more rapidly than the perimeter. This is again vastly increased in the low-pressure cylinder, where an extremely large volume exists with still smaller ratio of chilled perimeter. Taking all of the chambers into consideration, it is found that while retaining all of the chilled walls that are necessary for proper handling of the lubrication, still a gain is made on the order of 60 per cent in the extent of these chilled walls in the compound as compared with the simple engine.

With the large clearance volume we no longer have difficulty with solid injection, nor do we have any difficulty in using a wide range of heavy fuels. It has been known for years that as soon as the oil spray encounters chilled or even red-hot walls, the efficiency drops.[1] Here the oil fog may penetrate the deep masses of hot compressed air with instantaneous effect in every direction from the spray nozzle without encountering chilled walls and instantaneous and very complete combustion results. In the compound engine the clearance volume is so large that the entire high-pressure piston displacement causes it to lose only a fraction of its pressure, thus bringing to the second stage, or low-pressure, both ample volume and pressure so that this piston (representing 6, 8 or even 10 times the area of the high-pressure) is driven to the end of its stroke with pressures still above the atmosphere.

MUCH GREATER EXPANSION, HIGHER EFFICIENCIES

In this way the engine yields an expansion ratio based on gage pressures, which instead of being 3 or 4 to 1, as in the case of the automobile engine, or about 12 to 1 as in the Diesel, can be made as high as 120 to 1, yielding a higher return and greater efficiency from the fuel because of the lower temperature of the exhaust. The great volume in the combustion space furthermore allows this space, without distortion, to extend easily out over the top of the low-pressure piston, making a most direct connection therewith through a short transfer port (see L, Fig. 9).

THE COMPOUND CYCLE

Fig. 3 shows the cycle card without fuel, taken from the high-pressure cylinder in a 10 : 1 compound. The first-stage compression enters the cylinder at point A on its out stroke with the pressure about 113 lb., giving a power stroke indicated by line A'. At point B the induction valve closes and on the in stroke the compression proper starts and rises on line B' to Diesel values at C. There being no fuel injection, the receding stroke brings the pressures down on practically the same line B' to point B (E in Figs. 5

---

[1] See Eng-Comdr. C. J. Hawkes' Admiralty paper: Some Experimental Work in Connection with Diesel Engines, November, 1920.

and 6). Here the transfer valve opens and the gases pass on the in stroke to the low-pressure cylinder on line *D*. This is the out stroke of the low-pressure, the pressures sinking to a trifle below atmosphere before the final exhaust valve opens and continues open nearly during the entire next stroke of the low-pressure piston, which is, however, never shown on this high-pressure card but on the low-pressure card, Fig. 8.

Fig. 4 is the air-pump card representing the first stage of the compression which delivers air to a small receiver, from which air is delivered during the induction stroke, on line *A′* of Fig. 3, which, it will be observed, is a power stroke with a high mean effective pressure, thus recovering some of the power of the pump.

Fig. 5 is the same as Fig. 3, except that fuel has been injected, and shows the regular slow Diesel burning common to all early cards of these compounds, where from point *C* a perfectly level line is often drawn to point *C′* which marks the point of "cut-off." The gases then expand on line *C″* to point *E*, where the transfer valve opens and the gases continue to do work on the large area of the low-pressure piston, indicated by line *D*. The exhaust valve opens with pressures only slightly above atmosphere at point *D′*. The ordinary slow Diesel burning has the objection of lower efficiencies and allowing the heat to be added to the gases out nearer the exhaust end of the stroke.

Utilizing the Detonation of Fuels

Through a research extending over a year and a half or more, conditions were discovered by means of which "detonation" of the fuels may invariably be secured. This extends to a large variety, including of course the heavy fuels. While automotive engineers have adopted extreme measures, even lowering compression, "doping" fuels, etc., etc., in order to avoid the detonation, we have been working in the opposite direction. We have found that the *thermodynamic efficiency is higher in case of high detonation diagrams* than with low. Our work has been toward realizing these high efficiencies by developing instead of suppressing this high-intensity combustion. We have therefore sought to harness and utilize to the full the detonation phenomenon for the reasons and with the results outlined herein.

Fig. 6 is a typical card taken under the same conditions and the same engine as Figs. 3 and 5, exhibiting "detonation" and showing the quick burning, piling the heat up at the beginning of the stroke and as far away as possible from the exhaust end, giving also a very much truer Carnot-cycle card. All recent running of the compound engines has been in accordance with this card. One of the achievements of high-intensity combustion is better thermal efficiency and a still further reduction in the exhaust temperatures. The engine with this type of card is lifted from the old constant-pressure to the superior constant-volume performance which frees the compound from all speed limitations. The detonation characteristics, e.g., the vertical rise on the diagram, persist even at very high speeds. This card also insures operation at lower fractional powers without indication of carbon deposits.

Fig. 7 is given as showing the range of control of the peak and shape of the card at will under the same operating conditions and with the same spray nozzle.

Elimination of Losses in Transfer

In early attempts at compounding, principally layouts, it was found that prohibitive losses would occur in the transfer, due to the falling pressures while filling the low-pressure clearances. A complete solution of this is found in a special adaptation of the process of "cushioning"—closing the exhaust valve at a predetermined point before the out-stroke end, trapping a little of the hot gases and cushioning them up to the transfer pressure so the transfer valve opens under conditions of equal pressure on each side. There are practically no losses sustained in cushioning; the power of compression is returned very completely on expansion. The additional advantage is secured of preventing all erosion due to high velocities of the hot gases over the transfer seats. These seats are amply jacketed and are found to remain smooth, bright and perfectly sealed over long periods. It is incidentally found that in cushioning, the adiabatic compression of the hot gases brings with it an equality of temperatures as well as pressures, so there is neither loss in pressure nor temperature at this critical point of transfer and the efficiencies are carried at high values throughout the cycle.

Fig. 8 shows the low-pressure card, indicating the same power-pressure line *D* as Figs. 3, 5 and 6. On this in stroke the exhaust valve opens at *D′* and closes again at point *G* on the out stroke, giving rise to the cushioning curve *H*, terminating at the same pressure and really the same temperature as at *E* in the high-pressure cylinder.

The Transfer-Valve Problem

The point *X* in Fig. 2 will be recognized as being the same as point *B* in Fig. 3 and point *E* in Figs. 5 and 6. The transfer valve considered as an exhaust valve is here called upon to handle much hotter gases than ever heretofore. It must be remembered, however, that compression in the compound is by the modern two-stage method. Air is admitted to the combustion chamber under comparatively high pressure and although it is warm, yet with each atmosphere of pressure its cooling powers are doubled. Air at 100 lb. thus has seven times the cooling power of atmospheric air, seven times the weight and seven times the molecules in contact for cooling. In forcing the high-pressure piston down on pressure line *A′* in the above figures, air must pass some port in entering. Now, as a matter of fact, this port is in line with the transfer port and the induction valve itself rides on the back of the transfer valve in the form of a hollow sleeve *I* (Fig. 9) seated directly on the top of the transfer valve *T*. The back of the transfer valve is provided with greatly enlarged radiating and cooling surfaces presented to this cooling air and powerful convection currents are constantly acting when sealed. Moreover, this air when entering is at high velocity and gushes down through and bathes the deeply serrated surfaces of the back of the transfer valve, licking up the heat very completely in its inward rush.

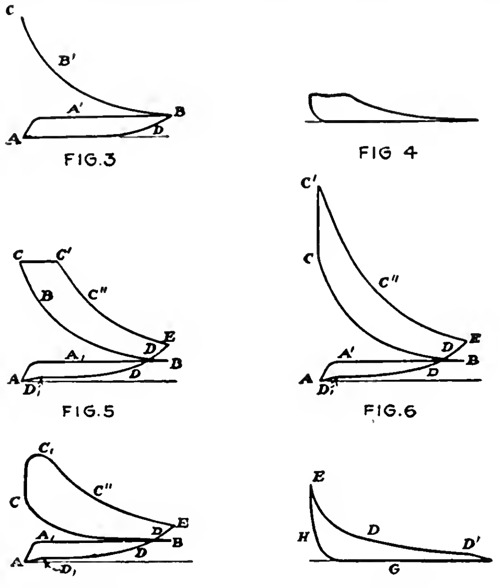

FIG. 3 FIG 4 FIG. 5 FIG. 6 FIG. 7 FIG. 8.

Figs. 3–8 Indicator Cards of Compound Cycle

Now in following out the cycle, it will be noticed that this is the very step that follows directly on the heels of the transfer of the hot gases (*D*, Fig. 3) and continues throughout the next quarter cycle (see *A′*, Fig. 3) and through the entire descent of the high-pressure piston, which in this way delivers a real power stroke to the crank with mean effectives in some instances greater than the mean effective pressures of the ordinary Diesel, thus returning some of the power taken to drive the supercharger or first-stage pump. If the transfer valve is intensely heated on its under surface (see *T*, Fig. 9) and is then instantly intensely cooled on a surface five times as great, it will certainly strike and maintain a heat balance which in practice is found to be extremely low, only about one-half the

temperature of the Liberty valves, nowhere nearly approaching red heat nor the temperature of normal Diesel exhaust valves under load conditions.

Again, the heat in these gases absorbed from the hot valve is useful inasmuch as it is the auto-ignition temperatures as well as pressures that are required at the end of the compression curve B'. Here a useful heat transfer and pure regenerative process is carried out. The seats give no trouble because they are backed by the ample water jackets and, in fact, the whole transfer valve gear operates continuously and successfully and is found to be in perfect condition after hundreds and even thousands of hours of operation.

How Lightness is Obtained in the Compound Engine

The question often asked is, To just what is due to smallness and lightness of the compound engine? It is this: In the four-cycle Diesel we have the tonnage of metal due to the presence of high pressures operating at a ridiculously low material efficiency because these high pressures persist only about $2\frac{1}{2}$ per cent of the total time. The Diesel card rises abruptly and immediately falls. All the rest of the time, over 95 per cent, either low pressures or no pressures at all are present, whereas in the compound the pressures *persist* and we are dealing with great blocks of power, as can be seen from the power curve C''. Although the pressures are not materially higher than in Diesel practice, they are made to persist practically clear across the card, producing a very large gross mean effective. This is instantly followed by another line clear across the card, again producing another large gross mean effective in the low-pressure cylinder when referred to the high-pressure area, all from a single fuel injection. Instead of 60 to 70 lb. net mean effective to the crank, delivering its power through a few degrees only of one stroke in four, in the compound we have two net mean effectives, each of 300 or 400 lb. per sq. in., succeeding each other and covering two strokes out of the four from a single fuel injection, giving very much better crank-effort distribution for power purposes. The point of paramount interest is that these two large blocks of power are secured *not by any material increase of pressures*, but by using large quantities of power gases, and "hanging on" to the pressures we have in those gases throughout practically two complete strokes, clear across the card twice, thus abstracting much more of the power they contain before exhausting. Suppose these to be 330 lb. per sq. in. each. Added they make 660, which is easily ten times 62 lb., a net mean effective not infrequently met with in ordinary Diesels. In an engine of simple construction giving ten times the net mean effective to its crankshaft and well distributed, there should be no good reason why it should weigh more than one-tenth the weight of the present Diesel.

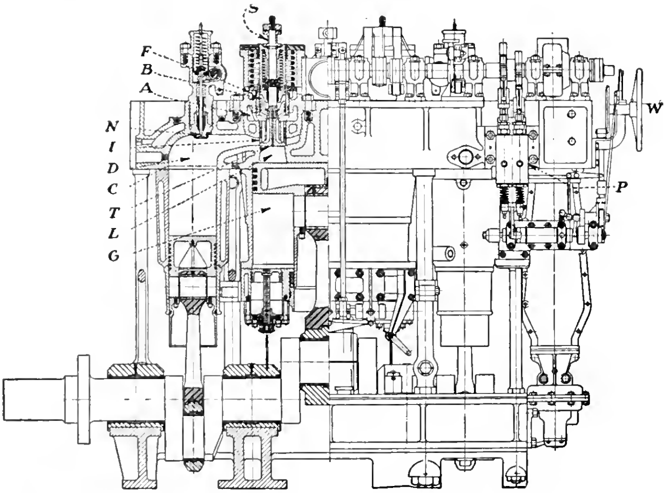

Fig. 9 Section and Elevation of Compound Oil Engine, Showing Construction

The power gases work in the Diesel about 120 deg. of arc and in the compound 315 deg., or 2.6 times as long; or, considering the points of "cut-off" in each, the true expansion curve is $3\frac{1}{3}$ times as long, which accounts for its large mean effectives and higher economies.

Proper Ratio for Compounds

As to the proper ratio for compounds, engines of 10 : 1 ratio of low-pressure to high-pressure cylinder areas, also 8 : 1 and 6 : 1 have been made, operated and studied, the smaller ratios being at present considered more desirable. The weight factor does not change materially with changes in ratio in this region. The low-pressure piston operates two-cycle. The power distribution and the weight of the reciprocating parts both equalize best at about 6 : 1. This makes a perfectly balanced unit, the end masses equaling and also moving oppositely to the central. The two full power impulses following each fuel injection are also about equal. Thus full *four-cylinder performance* is secured with only three cranks and two extra power impulses are delivered on the induction stroke (see line A', Fig. 3), making six power impulses for each cycle.

Another unusual advance should be noted, viz., complete reversibility and self air starting are secured without additional valves or cams over the simple, one-way engine without air starting, there being no difference in this regard. Again comparing the full-reversing, air-starting compound unit with a similar four-cylinder Diesel of any prominent make, delivering the same number of primary power impulses to the crank, the latter has 16 valves and 32 cams. The former operates the same cycle with two extra power impulses over the Diesel with 5 cams driving 7 valves.

Doing away with the three-stage air injection pump, its intercoolers and general complexity is another important simplification. One United States builder stated recently that an excess of 11 per cent of the entire power of the engine is absorbed for driving these pumps.

Marine Type of Compound Engine

Fig. 1 shows a 10 : 1 compound engine built for heavy duty. Although this is a small marine type with high-pressure cylinders 7 in. by 11 in. running at 400 r.p.m., yet the size of the crank-pitman end in the lower center of the engine reveals the ruggedness of these parts. The fuel pumps are also shown here and the connection to the governor. The camshaft is on a shelf at the top of the engine to one side and is driven by skew gears. The electric generator forming the full load of this engine is shown in the background and one of the transfer valves with its bonnet cover stands on the floor in front of the engine. The comparatively small size of the engine, although in the foreground, is notable and stands out in marked contrast with the engine of Fig. 10, the product of the largest Diesel builder. This is the standard marine engine for some seventy ships. The electric generator forming the full load of this engine (so marked) is also in the background, as in Fig. 1. The generators in the two cases of course being standard, give an unusually excellent basis of comparison. The compound works at a piston speed of about 700 feet per minute and its generator would be still smaller in comparison, should it be worked at the piston speed of about 900 feet per minute of the large engine. Incidentally, in the foreground of Fig. 10 there is also an excellent illustration of the three-stage, intercooled, high-compression air pump for spraying the fuel into the cylinders.

The large size and weight in the Diesels extends to all makes in somewhat different degrees. A line of Diesels made in the United States are reported to weigh 512 lb. per b.hp. The engine of Fig. 10 weighs 450 lb. per b.hp., while the compound in Fig. 1 weighs less than 30 lb. per b.hp.

Internal Construction of the Compound

Now as to the construction of the compound, Fig. 9 shows an elevation to the right of the center, and longitudinal section to the left, of the engine shown in Fig. 1. The two high-pressure or combustion pistons on their out stroke are at the ends and in the center the low-pressure at its extreme in stroke. The sturdy construction is indicated by the size of the crankshaft, about 50 per cent larger than in any other combustion engine of which the author has knowledge, approaching, as it does, the bore of the combustion cylinders

themselves. The fuel pumps *P* and the control and manipulating wheel *W* are shown in elevation to the right. To the left the large dome of clearance *D*, forming the combustion chamber of the compound, stands out in marked contrast to standard Diesel practice, which is shown by the little space *C* between the solid horizontal line at the base of the clearance and the dotted horizontal line just above. The dome is large and forms an upward extension of the combustion cylinder, extending also to the right in a large sweep surrounding the transfer valve *T* which seals the transfer port *L*. The sleeve-like induction valve *I* is shown seated on top of the transfer valve and is controlled by the cam-operated fork *F*. The transfer valve and sleeve are lifted by a fork not shown, located in thimble *S* near the top of the stem. The first-stage annular compression pump *G* surrounding the trunk piston below the low-pressure piston proper, delivers its air to a small receiver, which in turn discharges to the cored port *A* surrounding the induction sleeve *I*, the cooling action of which has been described. The little balancing cylinder *B* sustains a permanent connection with the low-pressure cylinder. The solid-fuel injection valve and nozzle *N* are placed approximately over the center of gravity of the large masses of air in the clearance dome *D*.

The comparison with the large dome constituting the clearance and combustion space in this compound with the small distance between the solid horizontal line at the base of the combustion space in Fig. 9 and the dotted line indicating the combustion space *C* in the normal Diesel, is simple to make and is significant.

It is understood that the two high-pressure cylinders are operating four-cycle, one 360 deg. back of the other, discharging alternately into the low-pressure, which therefore works two-cycle and delivers power on each down stroke. The cycle has been pointed out and the general operation will be apparent from this figure.

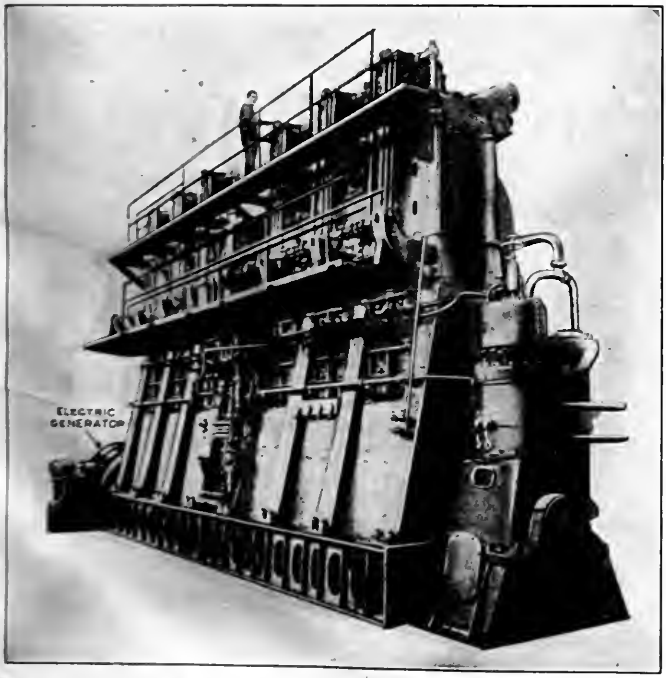

Fig. 10 Standard Marine-Type Diesel Engine

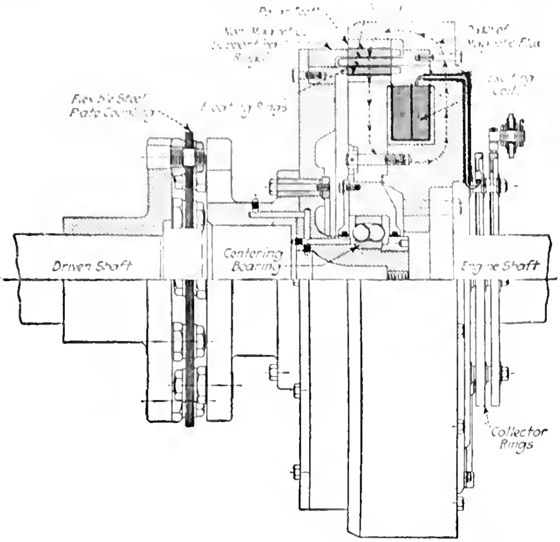

Fig. 11 Air-Gap Type of Electromagnetic Clutch

Field of Usefulness of the New Prime Mover

To engineers versed in the problems of selecting and designing prime movers, the advantages of the compound combustion engine are readily apparent. Its light weight for a given power with resulting low first cost and capital charge, the low costs for foundations, the high speeds with consequent low costs for connected generators, the small space required and the simplicity and economy of operation are important reasons for suggesting new fields for this prime mover, which has been proven of practical value in a long series of tests under working conditions. The compound engine is especially adapted for use for auxiliary or stand-by service in water-power stations or for carrying the peak loads in central stations where installations as large as 21,000 kva. have been contemplated. The important considerations are quick starting, non-deterioration of fuel reserve and flexibility of required fuel, amounting to almost complete independence of fuel quality. Other uses for the compound which readily suggest themselves are city water works and irrigation projects, either directly or by electrical distribution.

The possibilities of the compound-Diesel-electric locomotive should not be overlooked, as it presents all the well-recognized advantages of electric traction. At the same time it represents a component part of the central power station, with the advantage over the latter that it operates at the highest thermal efficiencies known—nearly three times the efficiency of even a very large power plant, i.e., three times the tractive effort is delivered to the rail from every pound of fuel burned. Also the capital charges for main feeders, substations, bonded rails and shunted switches and frogs, and the third rail or elaborate overhead construction are eliminated. The tracks are used exactly as they now stand.

Application to Ship Propulsion

We now come to the greatest present employment of oil engines, namely, their substitution for steam in ship propulsion. The advantages of motorships are rapidly being recognized, and they are now being built in practically every maritime country more rapidly than ever before. There were building last year 454,502 tons of Diesel-driven ships, or over 7 per cent of the world's total under construction. In the light of the past ten years' experience the Diesel engine has proved an efficient, reliable and thoroughly seaworthy prime mover, suitable for a large proportion of the total sea-borne tonnage.

Novel Electromagnetic Clutch Affords Elastic Drive

In connection with the development of the compound engine for marine purposes, and in order to provide any Diesel type of engine with speed flexibility equaling the reciprocating steam engine, there has been developed an electromagnetic clutch operating on an entirely new prnicple.

This new type of clutch transmits power entirely through air

gaps and has no mechanical contact whatever between the driver and driven, eliminating wear and deterioration. It is capable of remote control and can be operated at any speed from zero to full engine speed: the torque may be varied at will from maximum to minimum. The power required to operate the clutch at full load is but a small fraction of one per cent of the power transmitted. In one instance 525 hp. required 256 watts, or 0.065 per cent of the power transmitted. An outstanding feature of this clutch is that on direct drive or full speed it is magnetically locked, which insures perfect synchronism and no slip with an extreme increase in pull-out torque. At this and all times, in fact, the transmission has the "velvet touch" of an air drive and insures complete torquewise isolation of the mass moments lying on the two sides of the clutch. As seen in Fig. 11 the clutch forms a part of even a small-sized flywheel of either a Diesel or compound with little, if any, alteration of its mass moment.

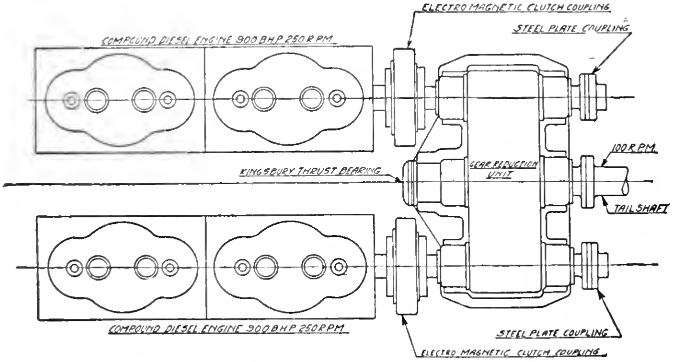

Fig. 12 Plan of Proposed Installation of Propelling Machinery

The clutch is characterized by two kinds of torque operating by opposite phenomena; the greater the differential or relative velocity between the driver and driven parts, the greater the torque available for starting and for bringing up to synchronism. This phenomenon also provides for slipping and continuous operation at all fractional speeds by means of the loaded secondary effect acting as an induction motor.

The air-gap clutch drives through magnetic flux comprising four ring elements, two of which are driving and two of which are driven. The flywheel proper accommodates an exciting coil producing the magnetic flux. At all fractional speeds or while this clutch is slipping, this magneto induction generates large currents in the driven elements which are now acting as short-circuited secondaries, producing heavy drag torques under perfect control by varying the amount of coil excitation. However, when the speed comes up in the vicinity of synchronism, locking occurs.

Proposed Installation of Propelling Machinery

Fig. 12 shows in plan view a proposed installation of the propelling machinery, securing the advantage to both engine and tail shaft of entire freedom of each to run at its own best speed. A propeller for a given ship has a speed at which it gives its most efficient performance; likewise a combustion engine can be built most economically and to give its best performance for a given size if the designer is given entire freedom to choose the best engine speed, a condition which is extremely desirable.

With this clutch and the engine combination shown in Fig. 1 several very important advantages are secured:

a There are available on a single propeller all the advantages and flexibility of a multiple engine equipment, where one engine may be shut down and completely disconnected for inspection, valve grinding, etc., and yet the ship be going forward at three-quarters its normal speed.

b Complete flexibility of the electric drive without the expense, weight and space of the electric generators and motors and the cumbersome electric control equipment for handling the heavy currents in maneuvering, and the double losses of generators and motors which are of substantial amount and a constant drag on plant and fuel economy.

c The simplest form of gear drive may be employed because the magnetic clutch allows the pinion to be a complete "floater." The pinion may thus accommodate itself to any want of precision and all sorts of idiosyncrasies of the main gear and teeth without shock. Any irregularities existing have to deal only with the small masses of the pinion itself and its stub shaft, being completely isolated from the large mass moments of the engine.

d The well-known irregularities in torque of any reciprocating engine and circumferential oscillation are entirely smoothed out by the air gap in the clutch and are not permitted to reach the pinion; its specific tooth operation is thus completely safeguarded. The crash and general irregularities of the engine torques thus never reach the pinion and therefore can have no effect on the complete smoothness of its performance.

e The torque, being under complete control, can be lowered so as to safeguard the equipment against overloading, especially when sailing in obstructed harbors, near derelicts, and where floating obstacles are likely to be encountered by the propeller blades, thus providing an important emergency disconnecting gear breaking away from the large engine masses and allowing the propeller to "stop in its tracks" through the self-interruptibility of the magnetic clutch when reduced to fractional underload condition. In this way many disasters to the propelling machinery and interruptions to the service may be avoided.

f Nearly all revolving machinery is subject to periods, sometimes running into severe "criticals." These criticals always develop from the irregularities in torque of the mass moments within the engine pitted against outside mass moments aft. This can occur only when these are solidly coupled with each other, but if instead they are isolated, as by the cushion or air gap of a magnetic clutch of proper design, these troublesome criticals with their excessive stresses are completely suppressed and can never develop.

g The combustion engine is reversible and runs equally well in either direction. The magnetic clutch solves completely all maneuvering problems, and in this way stands out in bold contrast to the difficult maneuvering and reversing conditions introduced by the non-reversible turbine.

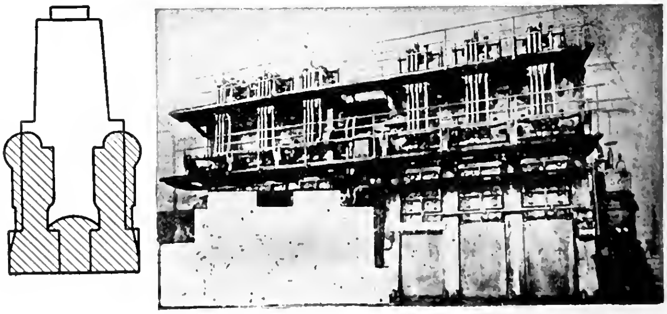

Fig. 13 Comparison between Compound Divided-Unit Geared Drive and Standard Diesel Engine Delivering to Tail Shaft the Same Power and Speed

As seen in Fig. 12, a Kingsbury or equivalent thrust bearing may be located forward of the main gear. The pinions flanking the gear on either side are not necessarily diametrically disposed. This gives an excellent distribution of the machinery, compact engine-room arrangement, and ample space for the small oil-engine generating sets for the ship, which incidentally also supply the clutches with the very trifling amount of energy and any other auxiliaries outboard of the engines. The engines are completely reversing and self-air starting, and either engine may be completely isolated at will. When either engine is running, the other may be gradually or quickly started up by means of the clutch instead of by air, if desired. The engines under this arrangement run with extreme smoothness and

(Continued on page 74)

Commercial Operation of Airplanes

By L. B. Lent,[1] New York, N. Y.

In order that those interested in the operation of airplanes for commercial use may have an idea of what may be expected of a properly organized and operated service, the author presents in this paper an analysis of the record of the Air Mail Service of the United States Post Office Department for the year ending Sept. 30, 1921. The operating record, the cost of operation, and the life and maintenance of planes and of engines furnish a basis upon which the author points out possible improvements, the most important in present practice being the use of efficient commercial planes equipped with a thoroughly reliable power plant. In regard to cost of operation, the author states that the total operating cost should not exceed 70 cents per plane-mile for single-engine planes of not over 400 hp.

It is the purpose of the author to present in this paper some information which may be found useful by those interested in the operation of airplanes as vehicles of transportation for profit.

Up to the present time there has been comparatively little such commercial service in this country and consequently there have been very few data developed which might be useful in an investigation and analysis of this important subject.

Commercial flying in Europe is developing very fast, but the conditions under which it is performed make it difficult to apply the information gained to operations in this country. A large part of the foreign service is devoted to carrying passengers and the operations are in many cases partly supported by government subsidies, and nearly all of the elements of cost are such as to make it difficult to apply the results to any proposed operation in the United States.

Fortunately, however, there has been a service in operation in the United States since May 15, 1918, which has rapidly developed into what may be properly characterized as the largest commercial operation of airplanes in the world; namely, the Air Mail Service operated by the Post Office Department of the United States Government.

This service is operated by a purely civilian personnel and is very similar in nearly all respects to that which would be effective in a purely commercial service. Moreover, the records of this service have been carefully kept during its entire existence, and if properly interpreted can be used as a basis for estimating the probable performance and costs of any commercial service of the immediate future.

Organization

The Transcontinental Air Mail Service operates daily in each direction between New York and San Francisco, an air-line distance of 2630 miles and a total daily mileage of 5260 miles. The various flying fields and the principal buildings located on each are as follows:

New York (Hazelhurst).	1 Hangar 1 Storage hangar 1 Office building
Bellefonte, Pa.	1 Hangar
Cleveland, Ohio	1 Hangar 1 Workshop 1 Office
Bryan, Ohio	1 Hangar
Chicago, Ill.	1 Large repair hangar 1 Storage hangar 1 Operating hangar 1 Office 1 Stock house 1 Test house with stands 1 Oil house
Iowa City, Ia.	1 Office; stock room and repair building 1 Tent hangar
Omaha, Neb.	1 Hangar
North Platte, Neb.	1 Hangar
Cheyenne, Wyo.	1 Hangar
Rock Springs, Wyo.	1 Tent hangar
Salt Lake City, Utah.	1 Hangar
Elko, Nev.	1 Tent hangar
Reno, Nev.	1 Hangar
San Francisco, Cal.	1 Hangar 1 Office

The airplane equipment now used in this service has been standardized and all machines are the De Haviland planes equipped with Liberty 12 engines turned over to the Mail Service by the War and Navy Departments. These machines are rebuilt to accommodate the mail load in the cockpit in front of the pilot and strengthened to meet the hard service required. A considerable amount of this equipment was turned over as indicated, and is stored in two buildings in Newark, N. J. This constitutes the major source of supplies for the entire service.

The total investment of the Air Mail Service is about $800,000, of which $133,000 is for buildings, trucks, tools, etc., the remainder being for airplanes and engines.

Equipment

It is obvious that the actual number of planes in serviceable condition and under repair may vary from day to day, but the following is a fair average figure for the year: In serviceable condition, 50; under repair, 18; awaiting repair, 30. During the year, 27 planes were damaged beyond repair and salvaged, while 48 new planes were placed in service and about 20 experimental types retired.

Engine equipment has always been in excess of actual need, because of the large number of Liberty engines turned over by the Army. The total number of Liberty 12A (Army high-compression) and Liberty 12N (Navy low-compression), developing about 400 and 350 hp., respectively, in use is about as follows: Engines in serviceable condition, in planes and as spares, 150; engines under and awaiting repair, 350. The foregoing figures do not represent the engine requirements for such a service.

An accurate estimate of the total engine requirements for this service can be based on the following: 22 engines are required for the 22 planes in daily service; at least 1 spare engine should be at each major station, making a total of 14; another supply of approximately 30 engines is necessary for those constantly in transit between the various fields and the overhaul stations, including the period of overhaul, making a total of 66 engines. If this service is properly organized a total of 75 engines is ample for successful operation of such a service.

Operating Record

The operating record for the past year is shown in Table 1. For a thorough understanding of these figures it is thought well to briefly outline the conditions under which the service was rendered.

The transcontinental course is divided into 13 legs of approximately 200 miles each with stations as given above. The route is divided into three major divisions—the eastern, extending from New York to Chicago, the central, from Chicago to Rock Springs, Wyo., and the western, from Rock Springs to San Francisco, Cal. It has been found that in the western trip the flight is hampered by prevailing westerly head winds, whereas the eastern trip is, of course, assisted by such conditions. Inasmuch as the supply of gas for each ship is approximately only four hours at cruising speed, it becomes necessary in many flights to stop at intermediate stations for service. Many times coming east, planes fly a major leg of approximately 400 miles. The number of such trips per month is somewhat varied, depending upon conditions.

While the available space in each plane accommodates 400 lb. of mail, the average amount carried per trip for the entire year was less than 150 lb. per plane per trip. These planes carry a pilot only, who flies a leg in one direction each day, returning to his home station the next day and laying off the third day. This schedule is, of course, subject to change, which occasionally results in a pilot doing more mileage than indicated.

The total flying time per day varies with the weather conditions, but the average speed for the entire year was 86.3 miles per hour; for the last 6 months (during better weather conditions) the average speed was 87.88 miles per hour. Up to the present time all flights have been made during the day. An indication of what is possible in a continuous trip, is the record established on Feb. 22 and 23, when the mail was carried from San Francisco to New York in elapsed time of 33 hr. 20 min., or a total flying time of 26 hr. 50 min. The fastest scheduled train time between these two

---

[1] Chief, Engineering and Survey Division, Aerial Transport Corp., Mem. Am.Soc.M.E.

Abstract of a paper presented at the Annual Meeting, New York, December, 1921, of The American Society of Mechanical Engineers. All papers are subject to revision.

points is 92 hr. The eastbound trip from Chicago to New York has been made in 5 hr. 30 min. The flight from Salt Lake City to San Francisco was made on Oct. 14, 1921, in 6 hr. 1 min. elapsed time, or a total flying time of 5 hr. 32 min. over a distance of 624 miles. The fastest train between these two points is scheduled for 24 hr. 15 min. It follows that, for the transcontinental distance, daylight flying only will cut train time about in half, and with night flying, the time is cut to about one third.

The operation record discloses one feature of special merit given under "Per Cent of Performance." It will be noted that the percentage of performance for the year was 88.33 per cent. For the last 6 months this average was 98 per cent, of which 96 per cent was actually completed on scheduled time. In view of the fact that the Pennsylvania Railroad in their printed timetables boasts of a train performance of 95.6 per cent on time, the foregoing record for the last 6 months is truly remarkable.

As to the effect of weather on the service, it will be noted that defaulted trips and the number of forced landings show a decided increase during the winter months. An interesting fact is that the number of forced landings from mechanical trouble also shows an increase, which would indicate the effect of cold weather on the quality of work done by mechanics.

During the year ten pilots and one mechanic were killed—four of the former during the last six months. This is equivalent to one pilot killed for each 169,756 miles flown.

TABLE 1 OPERATING RECORD OF THE U. S. AIR MAIL SERVICE. OCT., 1920—SEPT., 1921

Month	Trips Possible (Scheduled)	Trips Attempted	Trips Defaulted	Trips Uncompleted	Weather Encountered		Mileage Possible	Miles Traveled	Per Cent of Performance[1]	Mail Carried, Lb.	Forced Landings Due to

[1] For last 6 months, 98 per cent.

[2] May 31 — Last day's service on New York-Washington Route.

[3] June 30 — Last day's service on St. Louis-Twin Cities Division.

During the year 27 planes were so badly wrecked that they were salvaged instead of repaired, and there were 145 forced landings which resulted in damage to planes necessitating repair work; of these about 100 required major repairs. Obviously some were damaged more than once during the year. A further analysis of this as affecting the cost of operation is given later.

The large number of actual forced landings from mechanical trouble and other causes will no doubt attract attention as being excessive, and it should be noted that of the total number of forced landings only 172 resulted in damage to the planes. This is one plane damaged for every 10 forced landings.

It should, in fairness, be pointed out that all landings other than those regularly scheduled, even though made on an intermediate Air Mail field, are counted as forced landings.

Cost of Operation

The consolidated costs of operating this service for the yearly period chosen are shown in Table 2. It will be noted that there is no charge for interest on investment. This is of course a proper charge in any commercial service and should be added in any estimated costs. By making such a charge and adding it to the total costs shown in the table, it is thought that the figures resulting are safe and conservative for estimating the operating costs for any similar commercial line. In fact, the figures shown can be very much bettered if advantage is taken of the experience gained in the Mail Service.

An analysis and consolidation of the figures given in this table are shown in Table 3, which give the service and unit costs and the costs per mile for the year. In this table the total costs are divided into three general headings, namely, Overhead, Flying and Maintenance. Under the head of Overhead is included departmental overhead, office force and watchmen, motorcycles and trucks, rent, light, fuel, power, telephone, water and radio. Maintenance consists of miscellaneous, mechanics, helpers, repairs and accessories, and warehouse charges. Flying consists of gasoline, grease and oil, and pilots.

It will be noted that the mileages as shown in column 9, Table 1 and in column 3, Table 3, do not agree. The former figure is miles traveled in regular mail trips and the latter is "total miles" flown, which includes ferry trips, test flights and retrieving planes. The "total miles" is the proper basis for estimating costs per mile.

An examination of Table 2 will show that the largest items of cost are gasoline (15.0 per cent of the total), repairs and accessories (18.6 per cent), pilots (12.8 per cent) and mechanics and helpers (14.5 per cent). Considering these separately, it is seen that the gasoline cost cannot be materially reduced by the use of more economical engines, for even if engine economy is increased, say, 10 per cent (which is difficult), the total reduction would only be one tenth of 15 per cent, or 1.5 per cent of the total.

The largest item, repairs and accessories (column 4), is susceptible of considerable reduction. The elimination of forced landings and the damage resulting therefrom would largely reduce this charge. Fair wear and tear on places is relatively very small.

The basis on which pilots are paid, namely $2000 per annum, plus 5, 6, and 7 cents per mile flown, has proved to be very satisfactory, and more so than any other basis tried by the Mail Service. In all cases it supplies the men with a living wage and develops efficient service, which is rewarded by increased pay.

The pay for chief mechanics in the Mail Service averages $2000 per annum; other mechanics from $1400 to $1800 per annum; helpers from $1100 to $1400 per annum; and watchman and helpers from $900 to $1200 per annum.

An explanation of column 7 is essential. In most of the major fields the Mail Service was supplied with flying field, and in some cases with hangar facilities, by the cities in which they are located, without charge therefor. Rent for field and hangar facilities is paid at New York, Bellefonte, Pa., Cleveland, Ohio, Bryan, Ohio, Chicago, Illinois, and College Park, Maryland (training station). At all other cities west of Chicago no rent is paid.

This item of cost is therefore comparatively low and should be modified if used for estimating similar costs of a commercial line, unless similar arrangements could be made with various municipalities for use of municipal airdromes. If commercial companies have to purchase flying fields, as well as field equipment, it would of course, add largely to the capital costs, as well as the operating charges. It is believed, however, that very favorable arrangements can be made with most of the large cities in the United States for proper landing-field facilities.

The analysis shows that the average yearly operating cost per flying mile was 80.86 cents and for the last six months of the year, 71.83 cents.

As mentioned herein, if the cost is reduced to a ton-mile basis, the figures resulting will be unreliable; a fair basis of comparison is on a plane-mile basis, for it costs but little more to fly a plane loaded to its capacity than it does to fly it empty. It is a safe statement that under the conditions prevailing in the Mail Service, the cost per plane-mile will soon be reduced to the neighborhood of 60 cents.

With proper equipment and organization, a commercial service, using single-engine planes of not over 400 hp. each and flying only one round trip per day over a distance equivalent to that of the transcontinental service, can be accomplished for a total cost not exceeding 50 cents per flying mile. This is especially true if more than one round trip per day is flown.

TABLE 2 CONSOLIDATED COSTS OF OPERATING U. S. AIR MAIL SERVICE FOR YEAR ENDING OCT. 1, 1921

Month	Gasoline	Grease and oil	Repairs and accessories	Miscellaneous	Motorcycles and trucks	Rent, light, fuel, power, telephone and water	Office force and watchmen	Warehouse	Pilots	Mechanics and helpers	Radio	Departmental overhead charge	Total

LIFE AND MAINTENANCE OF PLANES

It may be noticed that in the foregoing no account is made of depreciation. In the present service no plane has remained intact long enough to wear out and so determine even approximately a rate of depreciation. Before a plane wears out most or all of the parts are replaced and charged up under that heading, or else it is so completely destroyed as to be retired from service, charged off entirely, with credit for such material as can be salvaged for use in repairing other planes. A fairly accurate idea of the rate of this destruction may be had from the following data:

During the year 27 planes were so badly damaged that repairs were not undertaken, these planes being salvaged. Of the many forced landings, 145 resulted in "crashes" necessitating repairs, of which about 100 necessitated major repair work. The number of "crashes" is thus about 10 per cent of the total number of forced landings. The average for the year is one "crash" for each 17,560 miles flown with mail; and for the last six months, 31,211 miles.

The number of planes required as original equipment to operate such a service as the Mail Service and the rate and cost of replacement may be estimated as follows:

1 plane for each of the 22 daily flights	22
1 spare plane for each daily flight, to be used in case of "last-minute" trouble with scheduled plane	22
1 spare plane at each of the 14 fields which may be in transit to and from repair shops and under repair........................	14
Total..	58

Mail-Service experience shows that after a plane has had about 450 hours in the air it is necessary to lay it up for a thorough inspection and reconditioning. This operation involves some labor and material (usually new wing covers, etc.) and costs an average of $600 per plane. The total time required for such an operation at present is about two months. Since the flying hours per year are 21,952, the total number of such overhauls is 21,952 ÷ 450 or 49. The record also shows that about 100 planes were so damaged as to require repairs. The average cost of these repairs was about $1000 each and the average time about two months per plane. The present rate of repair and overhaul for the entire Mail Service is about 11 to 12 planes per month.

It is thus seen that about 14 to 15 planes (about one for each 14 fields) must be constantly traveling to and from the repair shops and undergoing repairs. It should be stated that some plane repairs are made at many fields as well as at the main repair shop in Chicago.

An analysis of the above shows that:

- *a* The initial plane equipment is about one (1) plane for each 82 miles of scheduled flight
- *b* One (1) plane repair for each 16,975 scheduled miles flown
- *c* One (1) plane reconditioned for each 34,000 scheduled miles flown
- *d* One (1) complete "washout" for each 62,000 scheduled miles flown
- *e* The cost of conditioning 49 planes at $600 each = 1.8 cents per mile
- *f* The cost of repairing 100 planes at $1000 each = 6.0 cents per mile
- *g* The cost of "washouts" for 27 planes at $4000 each = 6.5 cents per mile
- *h* Total cost for repairs and replacements = 14.3 cents per mile.

This amounts to a total estimated cost of $238,000. Deducting this amount from the total in column 4 ($275,962), leaves $37,962, which it is fair to assume is the cost of engine overhauls and repairs, or about 2.25 cents per mile.

LIFE AND MAINTENANCE OF ENGINES

The record of engines actually replaced, repaired, salvaged, etc., is so involved in the records that it is difficult to discover the exact data. However, methods of maintenance, inspection and overhaul have been so developed and improved that it is more accurate to base an estimate on the present rate than to use total figures for the year.

Present methods of conditioning and caring for engines have resulted in an almost uniform service of 100 hours of running between each overhaul, unless an engine is damaged in some "crash." Since a total daily mileage with mail is about 5300 miles and the average speed is 86.3 miles per hour, the daily flying time is about 62 hours per day. To this must be added the time consumed in warming up engines (6 hours) and the time of engines on various test stands, so that the total daily time for the service is 80 engine-hours. This is equivalent to 0.8 engine replaced per day. Crashes, mechanical troubles and causes other than plain wear bring up the rate to just about 1.0 engine per flying day. While this may seem high, considering that only twenty-two planes fly regularly each day, it is not, for 100 flying hours per

engine between overhauls is a very high figure and can only be attained by the most efficient and systematic conditioning and repair methods in force in the Mail Service. While about 300 engines were used, the whole 300 were not actually overhauled, as many new engines were placed in service during this period. The yearly demand is, however, at about a rate of 300 engines per year.

This running time of 100 hours between overhauls is true even after the second and sometimes the third overhaul, the necessary replacements being made at each overhaul.

The average cost of an engine overhaul is as follows:

One mechanic and one helper, 10 days, 8 hours each	80 hours
Washing and valve grinding by other men	8 hours
Carburetor work, cleaning and adjusting	4 hours
Ignition work	4 hours
Block testing	6 hours
Total	102 hours

This total time may vary 50 per cent each way, but it is a fair average. The average labor cost is about $75 per engine. The average cost of the necessary material replacements, based on Government war prices, is $150. The average total cost is therefore $225 per engine. This cost may seem excessive, but is justified by the amount of careful and accurate work done, which is the real reason for 100 hours of further satisfactory service.

TABLE 3 ANALYSIS AND CONSOLIDATION OF FIGURES GIVEN IN TABLE 4 FOR PERIOD OCT. 1, 1920–SEPT. 30, 1921

	Service and Unit Cost					Cost Per Mile, Cents		
	Gasoline gal. (1)	Total Time, hr.-min. (2)	Total miles (3)	Cost per hour (4)	Cost per mile (5)	Overhead (6)	Flying (7)	Maintenance (8)

Average speed for the year $\frac{\text{Col. 3}}{\text{Col. 2}} = 86.3$ miles per hour

Average speed for the last 6 months = 87.88 miles per hour

Right here may be a proper place to point out the economy resulting from such methods. More frequent overhauls and a less satisfactory service record are a sure sequel to a lack of attention to the power plant, which is *the* important element. To illustrate, consider briefly the procedure employed in the Air Mail Service. Even a new engine is not assumed to be in proper condition. Nothing is "taken for granted." The method of conditioning of such an engine, and in general all engines after repair, may be briefly described as follows:

Even new motors are at least partly torn down to inspect the condition and fit of cylinders, pistons, piston rings, crankshaft and pin bearings, gears, etc. Crankshafts are especially checked for alignment, end play and proper condition of thrust bearings. Carburetors are carefully inspected and calibrated for both mechanical perfection and proper functioning, as are also generators, distributors, and other parts. The usual procedure is to put on every engine a set of carburetors, distributors, etc., which have already been inspected and calibrated in workrooms devoted to this special work. Such similar parts removed are turned into these departments for conditioning. All gaskets, especially those at carburetor and intake-manifold connections, are replaced with those whose condition is known to be good, thus preventing possible air leaks and improper carburation. Rubber-hose connections on gas, oil and water pipes are all replaced when necessary and it is usually necessary.

By using a timing disk, the correct timing of camshafts, valves and distributors is checked and the distributors for each bank of cylinders are synchronized both mechanically and electrically to within a quarter of a degree.

After a complete inspection and conditioning, the engine is run for about two hours at speeds varying from 300 to 1400 r.p.m. and also with wide-open throttle. After test, the engine is washed with kerosene and again inspected externally, and any faults which may have developed are corrected. All nuts are tightened, if necessary, all cotter pins are placed and securely fastened and the general condition made up to a *standard* and passed by the chief mechanic.

The foregoing constitutes a presentation of the mail record for the year, together with its analysis and certain deductions from this record, based on the author's experience in and knowledge of the Air Mail Service. It is assumed that some of the lessons learned in this service, and perhaps some of the opinions as to what improvements are possible, will be interesting, and they are accordingly set forth in the following paragraphs.

Improvements Possible

First and foremost, it must be apparent that the actual pay load (or mail load) carried is very small for planes powered with 400 hp., and if the cost of operation be reduced to a ton-mile basis, the results are not encouraging. However, it must also be evident that the costs really apply to a specific number of plane-miles, and not ton-miles, for it costs almost exactly as much to fly a plane empty as it does loaded. The mail planes carried an average load throughout the year of only about 133 lb. per trip attempted. As previously mentioned, the maximum mail load possible to put into the space available in the fuselage of these converted war machines was about 400 lb. These machines are now being remodeled to carry 850 lb. of mail. The important point, however, is that in a plane designed for commercial service, using the same Liberty 12, 400-hp. engine, and *costing no more to operate*, the *pay load should be all of 2000 lb.*

Another important point to bear in mind is that the mail planes make *one* trip each way per day. A commercial service operating several trips per day could do so without greatly increased overhead costs and at a considerably reduced unit cost of service. Just what the reduction would be, would depend, of course, on the number of trips made. Hence it may be fairly said that a most apparent improvement is a use of planes designed for commercial service, those which will carry a maximum load economically over a reasonable distance at high speed.

The cruising speed of such a plane should not be much, if any, less than 100 miles per hour. Head winds of 30 to 40 miles per hour are sometimes encountered, which slow down the actual ground speed by exactly that much, which means that the 100-miles-per-hour plane is traveling at (100–40) 60 miles, whereas a plane having an air speed of 130 miles per hour, or 30 per cent more, is doing (130–40) 90 miles per hour over the ground, or 50 per cent more than the 100-mile plane. Some carrying capacity should be sacrificed to speed in order to enable a plane to make time under adverse weather conditions. High speed also decreases the time required to fly a given distance and also decreases the total gas consumption, an important consideration, as will be seen.

Inasmuch as the fuel load is one of the factors in determining the size and weight of the plane, it is important that the fuel be used as efficiently as possible. The actual cost of the fuel burned is not so important as the reduction in the total fuel weight for a given flight, for this saving in weight may be put into added cargo; or, more important, it can be put into added power-plant weight, which will, in large measure, prevent forced landings. Overall

efficiency involves (*a*) reducing plane resistance, (*b*) increasing the loading per unit of wing area, (*c*) using a propeller of the highest possible efficiency, (*d*) running the engine, or engines, at nearly full power and (*e*) using engines of high specific economy. The effect of a proper combination of the above elements is to reduce first cost by using relatively small machines to do the work of large ones, which in turn decreases capital costs and further reduces the operating expense.

The question of reducing plane resistance, that is, increasing the ratio of the lift to drag (L/D), seems to have been given serious attention only in military or racing machines and has been ignored on commercial machines, especially of the multi-engined type. As the gross load which can be carried is equal to the thrust of the propeller multiplied by the ratio of the lift to drag (L/D) at a given speed, and as a low-resistance plane does not need to weigh more than one of higher resistance, it follows that the "usefulness" will be increased by increasing the lift-drag ratio, but in much greater proportion. For example, in an airplane making 100 miles per hour with a propeller efficiency of 80 per cent, the net available thrust is 3 lb. per engine hp. If the L/D ratio of such a plane is 6 at this speed, the total weight-carrying ability is 18 lb. per hp. If the weight empty is 10 lb. per hp., the net weight of the useful load is 8 lb. per hp. By increasing the lift-drag ratio to 9 instead of 6, the total weight-carrying ability will be 27 lb. per hp., and the net useful load 17 lb. per hp. instead of 8 lb. In other words, an increase of 50 per cent in the L/D ratio increases the useful load capacity 112 per cent, a gain by no means negligible and, in fact, not difficult to obtain.

Real airplane engine efficiency is not in fuel economy alone, although a low specific fuel consumption is essential. Contrary to more or less popular ideas, reliability is not a direct function of weight per horsepower only, for the mere addition of weight does not necessarily add reliability. As a matter of fact, the designers of recognized ability agree that airplane engines should be as light as possible. Lightness is an inherent quality of airplane-engine design and does not necessarily mean decreasing the factor of safety of important members below a safe figure. Making valves (for instance) much heavier would seriously interfere with their proper functioning as valves.

The best engines have a combined fuel and oil consumption of seldom less than 0.5 lb. per hp-hr. at full load, so that fuel and oil for a 5-hour flight is 2.5 lb. per hp., or more than the weight of a modern engine. It is therefore important that the fuel be consumed efficiently.

If the desire to "take off" quickly and climb rapidly is met, there must be much more power available than is required for economical cruising, and since all present types of engines have a higher *specific* fuel consumption when throttled, it follows that best results are to be obtained by some method which permits engine speed reduction with a nearly wide-open throttle. The variable-pitch propeller for single-engine machines is one solution of the problem.

Another solution is the multiple-unit power plant; that is, two or more power units driving a single propeller.

This brings us to a most important consideration in commercial operation, viz., the prevention of forced landings. Their elimination will practically insure 100 per cent service all of the time and materially reduce the amount of the largest single item of cost, viz., that of repairs of planes and engines. Until we can fly planes from one airdrome to another with certainty, even at reduced speed, we cannot obtain the best service records nor the lowest operating costs.

The author ventures to predict that the next most successful departure from a single-engine machine will be the multiple-unit plant using a single propeller. And further, that such a power plant will not consist of separate complete engines geared to one "stick," but perhaps of two, three, or even more, banks of cylinders on a common crankcase, which will also house the necessary shafts, gears and clutches in this rigid structure. All the units of such a power plant could be used in "taking off" and climbing to a safe altitude, after which one or more could be shut down and held in reserve to be put into service if required. Engine and propeller speeds in such a unit could be made such as to give maximum combined efficiency under normal operating conditions. The weight of fuel saved in such an efficient combination, over a reasonable length of flight, will compensate for the added weight of the "relay" units of such a power plant.

The experience of the Mail Service, as well as that of others, is that a landing chassis of ample strength saves many a "crash" in a forced landing, as well as in a hard landing on the flying field. If the landing gear stays together, much damage is averted, which otherwise might be serious. Large wheels and large tires have proved to be most useful, especially in rough and soft ground. In fact, the Mail Service uses Handley-Page bomber wheels on the DH4 machines as standard equipment and has operated them on soft fields, which would have been impossible with standard DH4 wheels and tires. Nor did these larger tires and wheels slow down speed to any noticeable extent. There seems to be almost no reasonable limit to the size of wheels which may advantageously be used.

In a large number of forced landings, where damage results, the front end of the machine only suffers, such as the propeller and the radiator and possibly the front end of the fuselage when the plane "noses over." This necessitates laying up the whole plane during the repair operation. To obviate this, some designers are using a separate quick-detachable nose, which carries the engine. The advantages of such construction are too obvious to warrant discussion.

It will no doubt be found desirable in commercial machines to use unit construction as much as possible, so that replacements may be quickly made and the damaged unit repaired at leisure.

Intelligent engineering attention to the many details of airplane design will be well repaid in more efficient operation and decreased cost. We do not need to seek for new or radical types with which to run a commercial service. The present types, properly engined, will deliver a most satisfactory service if handled by a properly organized and operated personnel.

Some idea of what a commercial plane, using a 400-hp. engine, can do, is given in the following data, which are based on accurate knowledge of proved performance. Such a plane having a lift-drift radio of 9, will not weigh over 5 lb. per sq. ft. of wing area. Besides fuel and oil for a 4-hour flight, together with a pilot and other accessories, such a plane will carry an actual pay load of 3000 lb. at a cruising speed of 100 miles per hour with the engine throttled down so as to be developing only two-thirds of its maximum 400 hp. Such a plane will cost no more to operate than the mail planes discussed herein.

CONCLUSIONS

While both the design and operating methods are susceptible of improvement, it is believed that the following are warranted from our present knowledge and experience:

- *a* The number of planes required for a given service is about one (1) for each 100 miles of scheduled flight
- *b* The number of spare engines required is about 50 per cent of the total number of planes
- *c* The total operating cost should not exceed 70 cents per plane-mile for single-engine planes of not over 400 hp.
- *d* Scheduled flights over reasonably long distances can be at least twice as fast as the fastest scheduled trains, flying in daylight only, and at least three times as fast if night flying is done
- *e* Night flying can be successfully accomplished with reliable power plants and a proper equipment of airdrome beacons and landing flares
- *f* The most important and desirable improvement in present practice are: the use of efficient commercial planes equipped with a thoroughly reliable power plant
- *g* The United States is admirably adapted to commercial airplane service because: (1) the large area permits long flying distances; (2) large centers of population well distributed over this area should supply ample business, and, (3) fast transportation of both goods and passengers is more in demand than in any other country in the world
- *h* The development of a large commercial service will furnish a reserve of planes, pilots, mechanics and other highly skilled men which would undoubtedly be the most valuable and effective part of our national defense.

Process Charts and Their Place in Management

By FRANK B. GILBRETH[1] and L. M. GILBRETH, MONTCLAIR, N. J.

The process chart is a device for visualizing a process as a means of improving it. Every detail of a process is more or less affected by every other detail; therefore the entire process must be presented in such form that it can be visualized all at once before any changes are made in any of its subdivisions. In any subdivision of the process under examination, any changes made without due consideration of all the decisions and all the motions that precede and follow that subdivision will often be found unsuited to the ultimate plan of operation.

In this paper the authors point out the place of the process chart in management and present established working data used successfully in numerous working installations for many years. They also point out its simplicity, field of application, its relation to standardization, etc., etc.

While the process-chart methods will be found helpful in any kind of work and under all forms of management, the best results can come, the authors state, only where there is a mechanism of management that will enforce and make repetitive the conditions of the standards.

The Process Chart is a device for visualizing a process as a means of improving it. Every detail of a process is more or less affected by every other detail; therefore the entire process must be presented in such form that it can be visualized all at once before any changes are made in any of its subdivisions. In any subdivision of the process under examination, any changes made without due consideration of *all* the decisions and all the motions that precede and follow that subdivision will often be found unsuited to the ultimate plan of operation.

The process chart is a record of present conditions. It presents, in simple, easily understood, compact form, data which must be collected and examined before any improvement in existing conditions and methods is undertaken. Even if existing conditions are apparently satisfactory, the chart is useful as presenting much information in condensed form.

The process chart serves as an indicator of profitable changes. It assists in preventing "inventing downward," and stimulates invention that is cumulative and of permanent value. It is not only the first step in visualizing the *one best way to do work*, but is useful in every stage of deriving it.

This paper presents established working data used successfully in numerous installations for many years.

Field of Application of the Process Chart

The process chart lends itself equally well to the routine of production, selling, accounting and finance. It presents both simple and complicated problems easily and successfully; it provides records that are comparable; it assists in solving problems of notification and interdepartmental discrepancies, and it makes possible the more efficient utilization of similarities in different kinds of work and in the transfer of skill.

During the stress of unexpected rush in production, it is often considered advisable to continue existing practice in present processes, even though inefficient. On the other hand, when production is normal or slow, it is more generally conceded that processes can profitably be bettered.

The use of this process-chart procedure permits recording the existing and proposed methods and changes without the slightest fear of disturbing or disrupting the actual work itself, and also regardless of whether business conditions are usual or unusual.

Those who are interested in improving their process of production should utilize times of industrial depression for that purpose. Many concerns are now taking such action; many more could undoubtedly enter upon such procedure of scrutinizing all their processes with the idea of putting them in the best possible condition, if they knew a simple procedure of such analysis.

Simplicity of the Process Chart

The aim of the process chart is to present information regarding existing and proposed processes in such simple form that such information can become available to and usable by the greatest possible number of people in an organization before any changes whatever are actually made, so that the special knowledge and suggestions of those in positions of minor importance can be fully utilized.

The time has passed—if it ever existed—when the engineer prided himself upon the abstruse material that he studied and presented. Today engineering ranks with the other sciences in conveying ideas in a form that is immediately usable. We avoid "translating," interpreting and adapting, thus eliminating waste.

The process chart has met the tests of a satisfactory teaching device from the psychological standpoint, as well as of a satisfactory working device from the engineering standpoint. It shows the planned process as well as the present process, and therefore gains the coöperation of those affected. In many instances recording industrial processes in process-chart form has resulted in astonishing improvements.

CHANGE ORDER No. 5

Fig. 1 Standard Change-Order Blank

Note that all blank forms should be thus numbered in each blank space to be filled out for describing clearly the One Best Way to Learn Work

Collecting the Information

Process-chart notes and information should be collected and set down in sketch form by a highly intelligent man, preferably with an engineering training and experience, but who need not necessarily have been previously familiar with the actual details of the processes. In fact, the unbiased eye of an intelligent and experienced process-chart maker usually brings better results than does the study of a less keen man with more special information regarding present practices of the processes. The mere act of investigating sufficiently to make the notes in good enough condition for the draftsman to copy invariably results in many ideas and suggestions for improvement, and all of these suggestions, good and bad, should be retained and filed together with the description of the process chart. These suggestions and proposed

---

[1] President, Frank B. Gilbreth, Inc., Mem.Am.Soc.M.E.

Abstract of a paper presented at the Annual Meeting, New York, December 5 to 9, 1921, of The American Society of Mechanical Engineers. All papers are subject to revision.

improvements must be later explained to others, such as boards of directors, managers and foremen, and for best results also to certain workmen and clerks who have special craft or process knowledge. To overcome the obstacles due to habit, worship of tradition and prejudice, the more intelligence shown by the process-chart recorder, the sooner hearty coöperation of all concerned will be secured. Any one can make this form of process chart with no previous experience in making such charts, but the more experience one has in making them, the more certain standard combinations of operations, inspection and transporting can be transferred bodily to advantage to the charts of proposed processes.

Utilizing Suggestions

A new viewpoint concerning old conditions invariably comes to those members of the organization who have become so accustomed to the traditional method that they cannot easily visualize a new method without prejudice until they actually see it in a new graphical form. After the rough notes of the process-chart maker have been redrawn and blueprinted, they are later exhibited in the executives' theater.

If discussions arise as to the correctness of the presentation of the existing facts, or as to further details of the operations being studied, as shown by the simple symbols of the process chart, the room can be darkened and inexpensive glass diapositives projected on the wall. In addition, those present may be supplied with a special pocket folding sterescope for use with the same glass diapositives.

As soon as the old or existing process is understood, a process chart of a better sequence and kind of operations which compose it is made. The procedure for this is the same for all cases as far as they are carried for the time being, but of course those processes which warrant the most study should be carried farthest in the process-chart procedure. The more people who see the process chart and the greater detail into which the regular process charts are divided, the more suggestions for improvement will come in.

Relation to Standardization

There is no process that warrants a process chart that does not warrant a "write-up" or "written system." The more care taken in making the written system, the more will develop the need for and appreciation of the value of clearly defined written standards. The better and the more detail in which the written system is developed, the better and easier will the standards and standing orders be developed.

Standards in writing should be made, even if there is not the managerial mechanism necessary to enforce and maintain them. Standards made even with enforcing mechanism absent will hasten the day when the enforcing and maintaining mechanism will be installed and continuously operated. The procedure of making the standards will invariably lead to the simplifying and improving of the various steps as shown on the process chart.

If it is desirable to study, improve and still further identify the subject-matter of each part of the process chart, it should be submitted to the regular routine process of standardization. A standard is a matter of degree. In its best form it is identified and defined with all the care and precision of the best practice for making the standing orders. The range, however, is dependent upon the degree of perfection with which provision has been made for enforcing and maintaining standards.

While on the subject of range, it is well to call attention to the remarkable attempts of Germany and Holland to provide national standards. These standards already cover a very wide field, from the style of the hand lettering and the rulings to be used on the paper on which the standards themselves are printed, to a metal seat for a harvester, tractor or tank. The range, in fact, already covers a surprisingly wide list of things which have not been properly standardized in America, and is intended eventually to cover everything that is manufactured in quantity, or that will for any other reason reduce costs or improve quality. Although there is much to criticise in these foreign standards, they are highly meritorious, worthy of continuous and careful attention, and a great credit to those who have devised them.

It must be remembered that the kind of standard adopted will affect the process almost invariably. Therefore standardization must be considered if the *one best way to do work* is to be derived.

Particular attention should be called to the fact that the creation of national standards of manufacture, even to the smallest components of the arts and trades, means also the stabilization of employment and business in general, because manufacturers without sufficient orders in their regular lines of business to keep going will find it more profitable, in many instances, to manufacture the

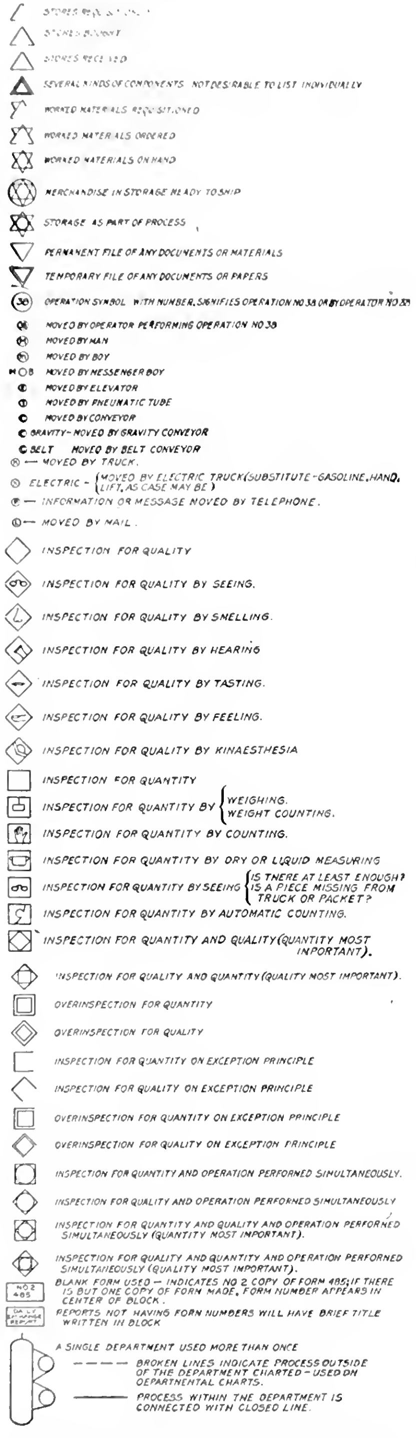

Fig. 2 Standard Symbols for Process Charts

national standards and thus to turn their stores inventories into money immediately, rather than let their specially trained and skilled men leave them, with all the disadvantages of a high labor turnover. Here is an endless spiral of benefit, for the more chances there are for a manufacturer to dispose of his inventory for cash and keep his organization together a little longer, even in times of general timidity, the more he will dare be a purchaser of raw material, for the process for such emergencies can be standardized and ready. The result is standardization, with stabilization of employment, a quick capital turnover and a low labor turnover.

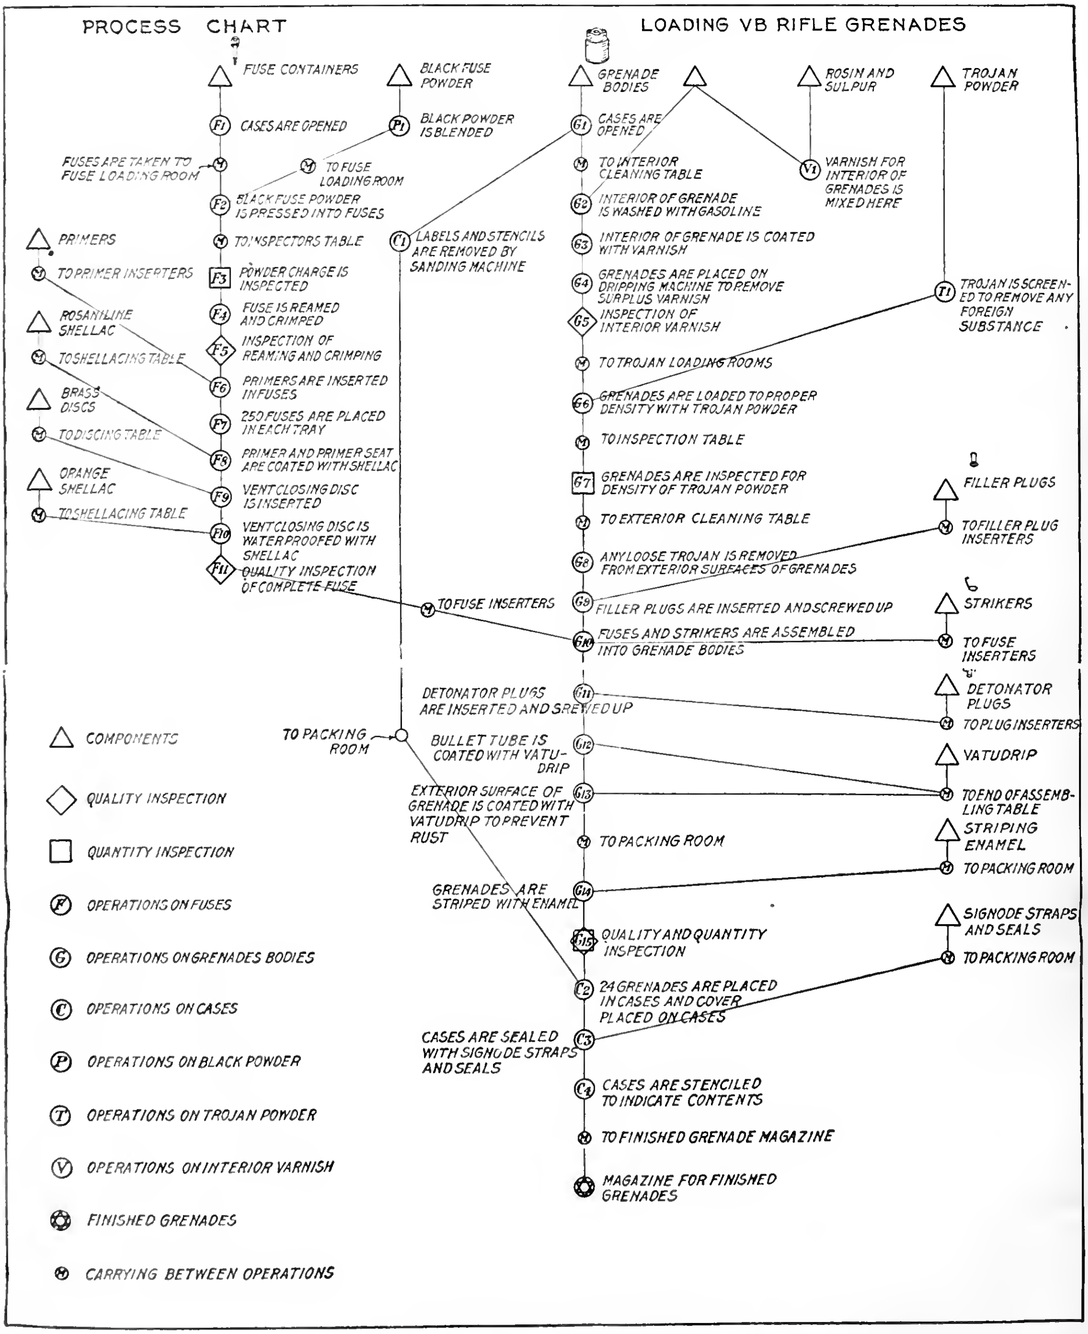

Fig. 3 Process Chart for Loading Rifle Grenades

Many fear standardization of the component elements of a process chart as something from which, once done, it will be difficult to escape. For the purpose of allaying such groundless fears, the standard change order, Fig. 1, has been provided. This, when signed by the authorized party, instantly changes, or for a certain instance, or a certain time, waives the existing standard whether it relates to a thing, a method, a procedure or a process. It will be noted that this change-order blank contains provisions for the notification of, and acknowledgment of receipt of notification of, all persons who are concerned with, or interested in, the change.

Note that in the lower right-hand corners of the various spaces in Fig. 1 there are small consecutive numbers. This is standardized to agree with write-ups and standing orders for using standard blank forms. It not only makes the writing of the standing order more simple, exact and clear, but it also shortens the time of the learning period for using these blank forms. This is a valuable feature at all times, but particularly useful during the transitory period of installing new methods of management.

Experience shows that if process charts are made use of, exceedingly few of the existing blank forms survive in their present form. The savings that can be made in any large organization resulting from submitting them to the test of this process will invariably prove it to be a good investment.

If all departments of the United States Government would adopt two features, namely:

- *a* Put small numbers in each space to be filled out on all of its blank forms, and
- *b* Make write-ups and standing orders of exactly how each blank form is to be filled out

and would then make a survey and criticism in accordance with the known laws of micromotion study, the resulting savings would be astounding.

We believe that, as a result, not one per cent of present blank forms would remain unchanged. All Government blank forms that we have seen violate all laws of motion study and learning methods of least waste.

The standing order is for enforcing standards and other standing orders. This has already been described in a paper before this Society.

The more detail in which the standing order is made, the better. The more the procedure is described by it, the greater will be the improvements and the greater the automaticity resulting.[1]

If any operation of the process shown in the process chart is one that will sufficiently affect similar work, then motion study should be made of each part of the process, and the degree to which the motion study should be carried depends upon the opportunities existing therein for savings.

If the operations are highly repetitive or consist of parts or subdivisions that can be transferred to the study of many other operations, then micromotion studies already made can be referred to; also new and further micromotion studies may be warranted in order that the details of method with the exact times of each of the individual subdivisions of the cycle of motions, or "therbligs," as they are called, that compose the one best way known, may be recorded for constant and cumulative improvement. Such motion study can be best visualized if seen in chart form, and similar process charts can be made of any or all of the large or small circles, squares and diamonds shown on the process charts. These subdivided motion charts can be made of each and all of the cycles in any given operation. Much benefit can often be derived, even if such motion charts are made roughly. For best results, and especially when complete records are required, such, for example, as when the process charts are of work that is highly repetitive, micromotion charts can be made which will give the maximum amount of analysis and visualization of component parts of the existing and proposed processes. These can be still further visualized by the chronocyclegraph process. Both the chronocyclegraph and the micromotion process have been described before the Society, and more recent development in these methods and devices for visualizing existing and proposed processes will be the subject of a later paper.

The records of the micromotion study and the chronocyclegraph methods and devices present permanently all the facts in such form that they can be used at any time. These photographic records can be studied as slowly as desired, regardless of how fast the motions of the process were actually made, and the marvels of the details of superskill, unknown and unrecognized even by those who possess it, can be studied at will, leisurely and intensively, by learners everywhere, far as well as near. If desired, these errorless records may be used only as far as to fill the need of present requirements, or they may be laid away until further needs demand further study, such records being in such perfect detail that they are practically as usable when old as when new. These permanent records of complete sequences of details of complete processes furnish the foundation of the best kind of trade and industrial education, namely, the dissemination of detailed instructions as to the synthesized processes of the best workers obtainable.

These synthesized records of details of processes in turn may be further combined and large units of standard practice become available for the synthesis of complete operations in process charts.

While the process-chart methods will be helpful in any kind of work and under all forms of management, the best results can come only where there is a mechanism of management that will enforce and make repetitive the conditions of the standards.

Mechanism of Making Process Charts

Summary

The procedure for making, examining and improving a process is, therefore, preferably as follows:

a Examine process and record with rough notes and stereoscopic diapositives the existing process in detail

b Have draftsman copy rough notes in form for blueprinting, photographic projection and exhibition to executives and others

c Show the diapositives with stereoscope and lantern slides of process charts in executives' theater to executives and workers

d Improve present methods by the use of —

1. Suggestion system
2. Written description of new methods or "write-ups," "manuals," "codes," "written systems," as they are variously called
3. Standards
4. Standing orders

DISCUSSION OF ENGINEERING EDUCATION

(Continued from page 7)

problems of the world had been accomplished without laboratories.

E. H. Sniffin[3] had always held the opinion that it might be a good thing if professors were to enter business life and later return to the schools. Probably ninety per cent of those graduated from engineering schools would be judged ten years later upon the basis of their qualities rather than their engineering knowledge.

Joseph W. Roe[4] said that it was utterly impossible for those who were trying to teach the specialist in an undergraduate course in any way to meet the full demands. The best that they could do was to send out men wellgrounded in the fundamentals, and in his opinion, more important than that, with a right attitude toward work and toward investigation.

H. B. Shaw[5] could see no reason why some engineering schools should not develop along the line of requiring the arts degree for entrance, and others develop graduate courses in engineering. There was really no need to have all of the engineering schools teaching engineering in exactly the same way.

K. G. Matheson[6] felt that the so-called collateral studies should more largely predominate as being essential to the highest type of the engineer; but unless something like adequate compensation could be offered so as to attract the very highest type of intellectual ability and training, that the standards of engineering colleges would certainly become more mediocre.

D. C. Jackson[7] wished to emphasize the fact that while Mr. Otterson suggested in his paper that the test in the engineering school seemed to be of a character that solely selected the encyclopedic mind, the truth was that the tests are, as a rule, intended to select men from the standpoint of the powers of analysis and synthesis. These powers were in fact those which led to a final balanced judgment and the accomplishment of the object was one that could not be left solely to the engineering school to bring about the best results. It was necessary to have the advice of the industrialists to arrive at the highest type of professional engineers. Professor Jackson's own definition of it, some years back, was that the highest type of professional engineer is one that can conceive exact ideas in important engineering works or in engineering affairs.

J. P. Jackson[8] defined an engineer as a man who should be in charge of all phases of industry except financial investigation. Most of the men who had discussed the subject spoke of the importance of character and he felt that stressing this before an engineering faculty every few days would do a great deal of good.

C. A. Adams[9] said that he had not heard anything so encouraging from the standpoint of teachers of engineering for many years as the two papers presented by the industrialists. It showed a great advance in the attitude of industry toward engineering education, and the emphasis of the two papers, could be summed up in a very few words, namely, more emphasis on fundamentals, the ability to think rather than a superficial knowledge of the practical side of the subject, the amount of cramming necessary. Our engineering education was for the most part brutally superficial. The men did not get the fundamentals. He would guarantee to take 100 picked graduates of electrical engineering schools of this country and show that 90 per cent of them had no grasp whatever of the fundamentals of maximum and minimum; that is, a sound grasp, a visualizing of phenomena and seeing through the mathematical equation into the physics beyond, so understanding the physics that they could express it directly in mathematical form. That was the difficulty with our engineering education. What was wanted in every engineer and every student was the habit of honest thought, the habit of demanding a sound foundation for his analysis in whatever field he is, and of building soundly on that foundation, and not the habit of thinking he knows something and throwing from his memory the things which he ought to know.

L. W. Wallace[10] said that the world, in general, had come to learn that the engineering type of mind, the engineering type of approach, was the correct type of mind and type of approach to apply to many of the perplexing problems that were confronting society and the world today. It should be instilled into young engineers that they were in not only a learned profession, but in one of great potential possibilities, and that it was not only their duty to do their technical work well but to make their ability and training and analytical minds felt in dealing with the social problems of the day.

W. H. Carrier[11] agreed with Professor Adams in his statement that ninety out of one hundred students did not understand the fundamentals of engineering. In many cases he had personally found it necessary to learn a great many of these fundamentals after he had left college. He was not a particularly backward student, but there were too many things to do, and not enough time in which to emphasize the fundamentals. The tendency of all education had been to place too much emphasis on quantity rather than quality. Students had not been taught to reason. They had been pushed along too fast.

R. L. Sackett[12] said that one thing characteristic of the curriculum of Pennsylvania State College that could not be blamed on the industries, was a lack of elasticity. All students who entered, say, the electrical course was not made in the same mold. They might be of equal mental capacity, they might have good minds, but it was quite impossible at the present time, in the present state of the art that vocationally they should be the same to any extent at the beginning of their college course.

Frank B. Gilbreth[13] said that in training the individual for accomplishment, judgment should not be developed until after all facilities for measurements had been exhausted. He was not prepared, however, to criticise the product of professors who had done such wonderful work for such inadequate rates of compensation. Something would have to be done whereby the graduates from the colleges, when they came to the industries, would be prepared to do something to teach the worker.

Sidney Ash[14] wished to emphasize a point that Mr. Pratt had brought out in his paper, namely, that there had been a considerable improvement in several all-around capacity of the average technical student turned out in recent years. He came in contact with a great many men taken in by his company as college graduates, and thought that this improvement was about 30 per cent in the types that were coming through today.

PREVENTION OF WASTES IN INDUSTRY

(Continued from page 10)

trol of the movement of material through the works from one operation to another and from one department to another; inadequate, or entire absence of provision for teaching or training operators, and minor executives; absence of effective means of recording attainments of workers, foremen, etc., so that their standing does not so much depend on actual performance as upon other things, some of them little if at all related to the work, such as nationality, religion, membership in secret organizations or fraternities, and sometimes plain graft.

When we set out to discuss an acknowledged fault our picture is necessarily rather a dark one. There is, of course, a bright side. We must work to make that bright side still brighter.

The greatest and most effective incentive for the prevention of industrial wastes is disarmament, so to speak; the cultivation of friendly relations between all those concerned in industrial enterprises; and the maintenance of such a system as will enable every man, from the highest to the lowest, to know what he is responsible for, to whom he is responsible, and that he personally will be credited and rewarded in proportion to service rendered.

Radio Ship Control

Details of the Mechanical Changes Made in the U. S. S. "Iowa," by Means of Which the Vessel Was Operated and Maneuvered From a Distant Control Ship

By REAR-ADMIRAL R. S. GRIFFIN,[1] U. S. N., RETIRED

Rear-Admiral R. S. Griffin

THE bombing tests which were carried out last summer against the old battleship *Iowa* (now designated Coast Battleship No. 4), during which that ship was operated and maneuvered under her own power without the presence on board of any of her officers or crew, created so much public interest that it has been suggested that a description of the mechanical changes that were made in her power equipment would be of interest to the members of The American Society of Mechanical Engineers.

The *Iowa* is a ship 360 ft. long on the water line, of 72.2 ft. beam, and at a draft of water of 24 ft. has a displacement of 11,346 tons. She has twin-screw vertical triple-expansion engines of 11,800 indicated horsepower which are capable of giving her a speed of 17-knots. They are, of course, condensing.

The problem presented was so to modify her power plant that the ship would be susceptible of control by radio energy from another ship, both as to speed and direction, without any person being on board; that under this condition she should be capable of steaming for at least two hours at a speed of about 10 knots; and that means should be provided for automatically stopping the engines and shutting off the oil supply to the boilers after fifteen minutes of operation following a failure of the radio control.

The first part of the problem obviously pointed to an oil equipment as the only one that could be considered, and as the *Iowa* was a coal-burning ship it became necessary to transform some of her boilers to oil-burning. The speed requirement of 10 knots necessitated the development of but a small fraction of full power, and therefore it was necessary to convert only one-half her boilers for steaming at a very moderate rate of combustion.

The boilers are of the Scotch or return fire-tube type, and therefore are not so well adapted to oil burning as are water-tube boilers. However, for the power that had to be developed, this presented no difficulty. The lining with firebrick of the combustion chambers and the front end of the furnaces, and the protection of the joint of furnace and combustion-chamber sheet were the only alterations that were necessary to the fire side of the boilers. Alterations to the furnace fronts were, of course, necessary to accommodate the oil burners. All these alterations are indicated in Fig. 1.

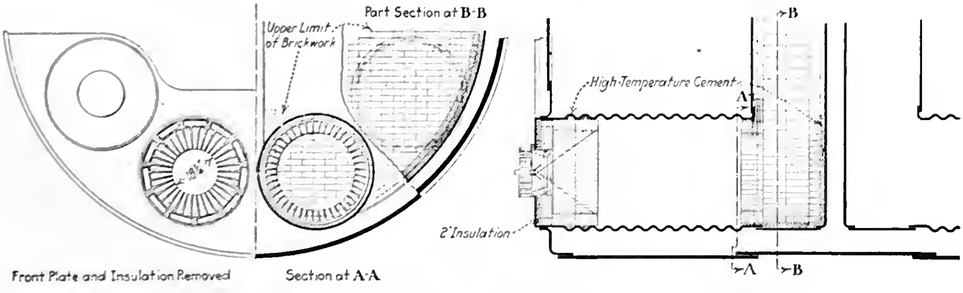

Fig. 1 Alterations in Scotch Marine Boiler to Adapt It to Oil Burning

Fuel-oil pumps were installed and were equipped with stop valves in their steam lines such that these valves could be instantly closed by radio signal if it were desired to stop the engines, or automatically in case of low water in the boilers.

In order to maintain a uniform water level, it was necessary to install feedwater regulators, which controlled the speed of the feed pumps in the usual manner.

The storage of fuel necessary to provide the continuous steaming laid down in the problem was easily effected by utilizing a few of the double-bottom compartments.

The only alterations that were necessary to the engines were certain modifications of the throttles to permit of radio control. The type of engines made it necessary to design for the condition in which the engines would be just turning over before the crew abandoned the ship, the function of the radio control then being to open the throttle to the extent necessary to secure the desired speed—which had been determined by test—and also to stop the engines should it be necessary so to do. The control was so effective that no difficulty whatever was experienced in controlling the speed, slowing down being accomplished in twenty seconds and increase to full speed in three minutes.

Such auxiliaries as air pumps, circulating pumps and bilge pumps, the operation of which at normal speed would have no material influence on either the speed of the engines or the boiler conditions, were unaffected by the conditions of the problem and were untouched after once having been set at the proper speed of operation.

The points that have thus far been mentioned pertain solely to the propulsion of the ship. In order to maneuver her, which was one of the most important considerations in connection with the bombing tests, it was necessary that the steam steering engine be under as complete radio control as the main engines. Ordinarily this is accomplished through wire-rope transmission from the steering wheel on the bridge to the shaft which operates the engine-control valve. For this test a small motor was installed and connected by chain drive to the control-valve shaft. It was provided with an automatic reversing contactor controller which was operated through the radio-control panel or automatically through the gyro clutch. It proved to be an admirable substitute for the hand steering wheel.

Naturally, considerable electric energy would be necessary to operate the various radio circuits and apparatus, but as operation of the ship's electric plant during the test would unnecessarily complicate the problem without supplying any useful information respecting the results which it was desired to accomplish, it was decided to provide storage batteries and control panels for the several circuits.

In preparation for radio control the oil-fuel pumps, the air and circulating pumps, the feed pumps, an air compressor and a bilge pump are put in operation, and the steering engine warmed up and operated by hand control. When normal conditions are

---

[1] Washington, D. C. Hon. Mem.Am.Soc.M.E.

established, the main engines are started and kept running at dead-slow speed, the bridge control of steering engine thrown out, all batteries connected to bus bars, and switches to radio-control instruments and gyro compass, and steering-engine motor thrown in. Everything is now in readiness for radio control and the signal given to "abandon ship." As soon as the boats that take off the crew are clear of the ship, she is immediately put under radio control by the control ship, which in this case was the battleship *Ohio*, which during the past two years has rendered excellent service in radio experimental work under the Bureau of Engineering of the Navy Department.

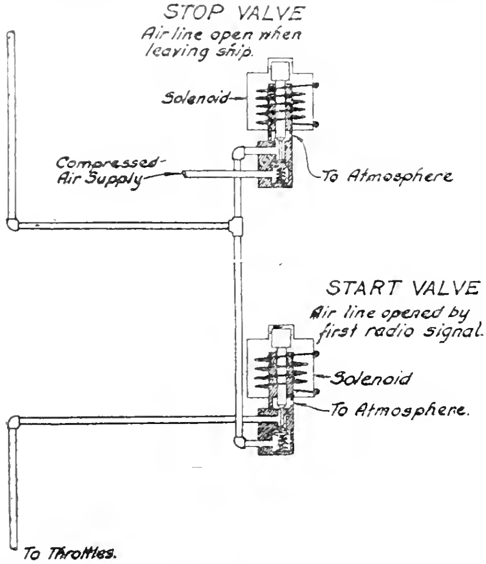

FIG. 2 RADIO-CONTROL VALVES FOR OPENING AND CLOSING THROTTLE-CONTROL VALVE, FIG. 3

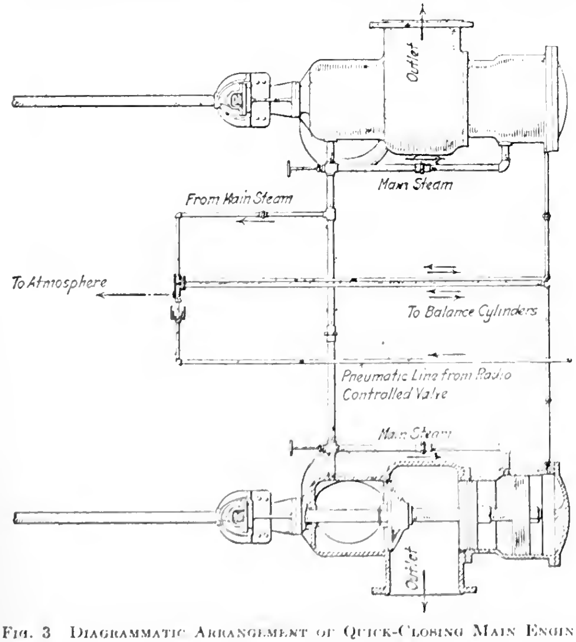

FIG. 3 DIAGRAMMATIC ARRANGEMENT OF QUICK-CLOSING MAIN ENGINE THROTTLE VALVES AND CONTROL VALVE

The method of control will be understood from the following:

When the air compressor is started, pressure is brought up to the "stop valve," Fig. 2, which may be called the master radio-control valve. This valve is then energized from the ship's control room, by which action air is admitted to the balance cylinder of a quick-closing valve in the steam line to the fuel-oil pump and up to the "start valve," as indicated in the sketch. The first signal from the control ship energizes the "start valve," Fig. 2, which admits air to the piston of the throttle-control valve shown in Fig. 3. This throws the piston to the left, shuts off steam from the upper balance pistons, and the throttles open to the extent necessary for the desired speed, the lower balance piston being smaller in diameter than the upper one.

The opening by the control ship of the radio circuit to "start valve" closes the valve to air pressure under the action of the spring, and the pressure in the line to throttle-control valve is released. When this occurs, the piston valve is thrown far enough to the right to uncover the port to the steam pipes leading to the upper chambers of the balance cylinders and the throttles close under the action of the steam pressure.

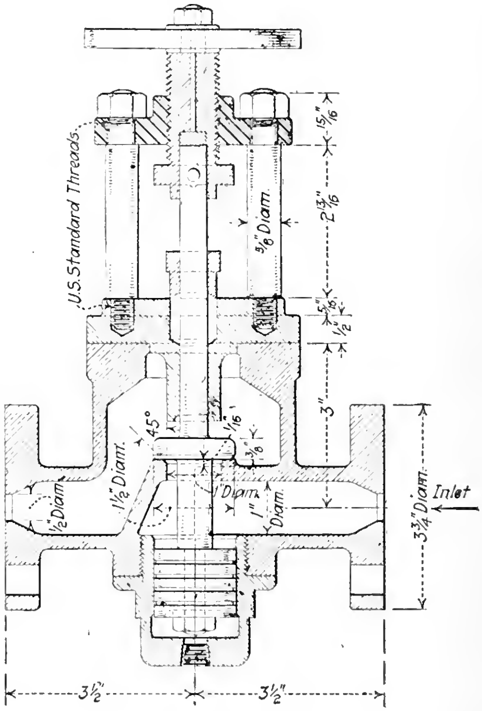

FIG. 4 TYPE OF VALVE USED IN CONTROLLING FUEL-OIL PUMP

Similar action takes place when it is desired to stop the fuel-oil pump. The proper opening of the steam valve to this pump having been previously determined and air pressure being on its balance piston, a radio signal releases the air pressure, whereupon the valve closes automatically under the influence of steam pressure on the other side of the balance piston. The throttles close at the same time. Fig. 4 shows the type of valve used.

The requirement that the engines and the fuel-oil pumps should stop automatically after a certain lapse of time in case radio control failed was accomplished by the introduction of a "time limit clock" in the "stop valve" circuit. After the lapse of time for which it had been set, the clock opened this circuit, and the steam valves to the oil pumps and the engine throttles closed in the manner previously described.

The low-water alarm was of the usual type except that, instead of blowing a whistle, the steam was used to operate a piston that opened the "stop valve" circuit.

The principal radio-control apparatus is covered by patents of John Hays Hammond, Jr., who permitted the free use of it for this test. It was constructed by the General Electric Company under the supervision of Mr. Hammond and the Bureau of Engi-

(*Continued on page 70*)

Code for Displacement Compressors and Blowers

Preliminary Draft of the Fifth in the Series of Nineteen Codes in Course of Preparation by the A.S.M.E. Committee on Power Test Codes

In 1918 the Power Test Committee of the A.S.M.E. was reorganized to revise and enlarge the Power Test Codes of the Society, published in 1915. The Committee is a large one, consisting of a Main Committee of 25 under the chairmanship of Fred R. Low, and 19 Individual Committees of specialists who are drafting codes for the different classes of apparatus comprised in power-plant equipment. Below is reproduced the fifth of these codes to be completed, namely, the Test Code for Displacement Compressors and Blowers.

The Individual Committee which developed this Code is headed by Mr. Paul Diserens as Chairman, and consists of the following men: Hugh V. Conrad, John F. G. Miller, Snowden B. Redfield,[1] Carl G. Sprado, Charles Prentice Turner, and John T. Wilkin. This Committee will welcome suggestions for corrections or additions to this draft of its Code and especially desires constructive comment on Pars. 10 and 10a. These should be addressed to the Chairman, care of The American Society of Mechanical Engineers.

Introduction

1 The code for displacement compressors and blowers is intended as a guide for testing reciprocating piston compressors and blowers, as well as rotary compressors and blowers of the positive displacement type. The tables for data and results apply to complete units, including compressor element and driving element, but the code itself constitutes a set of rules for the test of the compressor element only. For the driving element the codes for steam engines, steam turbines, internal-combustion engines, water wheels, etc., depending upon the method of drive, should be consulted and followed.

Object

2 In accordance with the "General Instructions," the object of the test should be determined and recorded. If the object relates to the fulfilment of a contract guarantee, an agreement should be made between the interested parties concerning all matters about which dispute may arise, as noted in Par. 2 of the "General Instructions," and the points agreed upon should be stated in the report of the test.

Measurements

3 The measurements to be made in any test of a compressor or blower have for their purpose the determination of the following essential quantities:

(*a*) The quantity of air or gas compressed and delivered expressed in cubic feet in terms of gas or air under intake conditions of temperature and pressure
(*b*) The average intake and discharge pressures
(*c*) The power required to compress and deliver the measured amount of air or gas handled
(*d*) The amount of steam, electrical energy or fuel, depending upon the method of drive, consumed by the driving element during the test.

In order to arrive at these quantities and as a means of interpreting them, the following measurements are necessary:

(*e*) Diameter and stroke of compressor cylinders, or equivalent dimensions for positive rotary blower
(*f*) Diameter of piston rods
(*g*) Number and dimensions of intercoolers and aftercoolers
(*h*) Principal dimensions of driving element (See appropriate code)
(*i*) Speed in r.p.m. and total number of revolutions
(*j*) Indicated horsepower in compressor and driving cylinders (steam engine, internal-combustion engine, etc.)
(*k*) Discharge pressure
(*l*) Intake pressure
(*m*) Intercooler pressure
(*n*) Barometric pressure
(*o*) Temperature of air or gas before and after each stage
(*p*) Temperature of cooling water at inlet and outlet of each jacket and cooler
(*q*) Quantity of jacket and cooling water
(*r*) Temperatures, pressures, etc., steam, gas or oil as applied to driving element (See appropriate code).

Instruments and Apparatus

4 The instruments and apparatus necessary for the measurement of the quantities enumerated in Par. 3 are:

(*a*) Gaging tank and nozzle or orifice for measuring air or gas compressed
(*b*) Tanks and platform scales of suitable capacity for measuring the quantity of condensed steam when a steam engine constitutes the driving element or for measuring fuel oil when an oil engine constitutes the driving element
(*c*) Water meters or calibrated tanks, or tanks and platform scales for measuring jacket and intercooler circulating water
(*d*) Pressure gages, vacuum gages, water and mercury manometers, and thermometers
(*e*) Barometer
(*f*) Steam calorimeter (for steam-engine-driven compressor)
(*g*) Voltmeter, ammeter, wattmeter and power-factor meter for measuring electrical input for motor-driven compressors
(*h*) Revolution counter
(*i*) Indicators
(*j*) A planimeter
(*k*) A deadweight gage tester

Directions for the use and calibration of instruments and apparatus enumerated above are given in Pars. Nos. —— of the code on "Instruments and Apparatus."

4a The measurement of the quantity of air compressed shall be by the following method:

(*a*) In the case of a compressor or blower: Flow into the atmosphere through nozzle or orifice from a gaging tank on the discharge side of the compressor or blower
(*b*) In the case of a vacuum pump: Flow from atmosphere through a nozzle or orifice into a gaging tank on the intake side of the vacuum pump.

4b Where the foregoing prescribed method is impracticable, as for example in the case of a compressor handling inflammable gas or gas which cannot be wasted, one of the following instruments may be used. These alternatives are listed in order of preference.

(*c*) Venturi meter
(*d*) Nozzle or orifice in discharge line
(*e*) Receiver tanks of known capacity into which the discharge from the compressor may be delievered, to be used only for compressors working at a discharge pressure of 1000 lb. per sq. in. or greater.

If method (*c*) or (*d*) is used, the instrument should be applied in a pipe through which the gas is permitted to flow under a pressure considerably less than the compressor discharge pressure. The reduction in pressure can be brought about by throttling and will result in eliminating, or at least minimizing, the pulsations in flow induced by the compressor.

4c The kind and size of gaging tank and nozzle or orifice selected will depend upon the particular method chosen for measuring the quantity of air or gas compressed. Whenever possible a low-pressure nozzle or orifice shall be used. A low-pressure nozzle is one through which the drop in pressure is small, that is, one in which the upstream absolute pressure is less than twice the downstream absolute pressure. Its use for high- or moderate-pressure compressors involves throttling the gas before it is admitted into the gaging tank to such an extent that all, or nearly all, pulsation is eliminated. If a high-pressure nozzle is selected, that is, one through which the drop in pressure is relatively large ($P_1 > 2P_2$), care should be exercised to select an orifice of a size sufficient to insure as much throttling between the discharge receiver and the gaging tank as possible.

4d The measurement of the intake and discharge pressures shall be by gage attached at the desired point, the fluctuations of which are reduced as far as may be by choking the gage cock. When extreme accuracy is desired or when the fluctuations are large, the average pressure may be found by working up pipe diagrams taken at or near the same point, thereby determining the mean pressure for the entire stroke.

---

[1] Mr. Redfield approves the draft of the Code as here printed with the exception of Par. 10a. *He* believes that the amount of moisture removed in the separator should be weighed and that this weight should enter into the calculations.

PREPARATION

5 Before proceeding with a test of a compressor or blower, Pars. 4 to 8 of the "General Instructions" should be carefully read. The dimensions and physical conditions not only of the compressor but of all the associated parts of the plant essential to the object of the tests should be determined and carefully recorded.

5a *Dimensions.* The dimensions of the compressor cylinders should be determined by actually measuring the machine itself without reference to the drawings. If the cylinders are much worn the average diameter should be taken, but proper record of the fact should be noted.

5b The method for measuring clearance will depend upon the particular design of the compressor in question. In a reciprocating displacement compressor with valves of the automatic type, the most satisfactory method will be to calculate the clearance from the measured dimensions of the cylinder, its several ports, and passages. If detailed drawings are available it will be found convenient to check each dimension of the parts involved by actual measurement and from this information compute the clearance volume. If mechanically operated valves are used, or if the construction of the valves of the automatic type is such as to permit blocking them in their closed position, the clearance may be obtained by the water-measurement method. This should only be attempted, however, when extreme accuracy is necessary or desirable. To carry out this method, refer to Par. 5a of the Code for Steam Engines.

5c The area of the compressor cylinder-jacket surface is that part of the cylinder wall or cylinder-head wall in contact with the water circulation and should be measured on the dry side of the metal.

5d The intercooler and aftercooler surface should be measured on the dry side of the cooling surface. Surface in contact with the air to be cooled on the one side and atmospheric air on the other side should not be included as cooling surface. If a record of its amount is made it should be listed as a separate item.

OPERATING CONDITIONS

6 As pointed out in the "General Instructions," Par. 19, in all tests in which the object is to determine the performance under conditions of maximum efficiency, or where it is desired to ascertain the effect of predetermined conditions of operation, all such conditions which have an appreciable effect upon the efficiency should be maintained as nearly uniform during the trial as the limitations of practical work will permit.

Tests to determine the performance under working conditions in which no attempt at uniformity is made are not advised, since the only available method of air measurement involves the determination of the rate of flow and total quantities of gas or air must be computed from the observed rate. Unless all conditions of operation are kept uniform or nearly uniform, the results obtained will not be of any value.

STARTING AND STOPPING

7 The compressor should be operated under test conditions for a considerable period before a record of its performance is made. This period should be of a duration sufficient to bring about a steady condition of pressure, temperature and speed. In this connection Pars. 16 and 18 of the "General Instructions" should be carefully noted

DURATION

8 The duration of compressor tests will generally be governed by the requirements in so far as the driving element is concerned, and for direction as to the necessary period reference to the appropriate code governing the driving element should be made. In the case of a motor-driven unit accurate results can be obtained from very short tests, the controlling factor being the time required to record enough sets of observations to demonstrate the uniformity of running conditions during the test.

RECORD

9 The general data should be recorded as pointed out in Pars. 20 to 30 of the "General Instructions." Instruments should be read and indicator cards taken from each end of each cylinder at least quarter-hourly when the conditions are uniform, and oftener when there is much variation. For short tests referred to in Par. 8, readings and cards should be taken much more often. If there are wide fluctuations in readings they should be shown by recording instruments. Each indicator card should be marked with the number, date, time, scale of spring, and end of cylinder, and on one card of each set the readings of the pressure gages should be recorded. The log should contain the record of the readings of discharge, intercooler and intake gages, thermometers, revolution counter, speed indicator, gaging-tank pressures and temperatures, and all other instruments, and these readings should be obtained at practically the same time the indicator cards are taken. The areas, lengths, and mean effective pressures shown by the indicator cards should also be entered in the log. If complete test data are required, representative pipe diagrams should be taken with an indicator applied near the cylinder port and operated by connection to a reducing motion driven from the engine or compressor crosshead.

9a A set of specimen indicator diagrams should be carefully selected from the whole number taken, and these should be embodied in the record. The specimen cards selected should be such as to show the average conditions of pressure. If pipe or port diagrams are obtained, specimens of these should also be placed in the record.

CALCULATION OF RESULTS

10 *Volume of Air or Gas Compressed.* The measurement of the amount of air or gas through a nozzle, orifice, or venturi tube results in a determination expressed in pounds per unit of time. (See Code for Instruments and Apparatus, Par. —.) The results obtained must therefore be reduced to terms of volume at the temperature and pressure obtaining at the compressor or blower intake. For this purpose the required specific weight at intake conditions may be calculated from the following formula:

$$\text{Specific weight} = \frac{P \times 144}{RT} \text{ in lb. per cu. ft.}$$

where P = absolute intake pressure, lb. per sq. in.
T = absolute intake temperature, deg. fahr.
R = constant (=53.3 for air).

This assumes that the fluid compressed is ideal gas, an assumption quite satisfactory for air. The weight of air or gas per minute as shown by nozzle measurement divided by the specific weight at intake conditions is equal to the volume of free gas or air compressed per minute.

When natural gas is compressed the value for R is not nearly enough constant under all conditions to satisfy engineering requirements and a correction must be made, depending in amount on the ratio of compression and the nature of the gas. (See Code for Instruments and Apparatus, Par. —.)

10a[1] *Correction for Moisture.* In the case of a compressor handling moist air, if some of the moisture is condensed during the process of intercooling and aftercooling, the air under discharge pressure will be saturated. In order to correct the rate of flow as shown by the orifice results it will only be necessary to figure the capacity of the compressor in terms of a total pressure equal to the sum of the partial pressure of air under intake conditions plus the partial pressure of the moisture in moist air having a relative humidity less than that observed in the intake by an amount representing the moisture removed in the cylinders, intercoolers, and aftercoolers. To determine this equivalent pressure to be used in calculating the specific volume, the following formula may be used:

$$P = P_d + P_m$$

where P_d = partial pressure for air in intake
P_m = partial pressure of moisture corrected for water of condensation removed from compressor and coolers.

To arrive at the value for P_m, proceed as follows: In the steam tables find the density of steam corresponding to the observed temperature in the discharge receiver. Multiply this first by the ratio of the observed absolute intake pressure to the observed absolute discharge pressure and then by the ratio of the absolute temperature in the discharge receiver to the absolute temperature

---

[1] See footnote on preceding page.

in the intake. The value thus obtained will be a hypothetical density, opposite which in the pressure column of the steam table will be found the desired partial pressure P_w.

It should be noted that the correction for moisture may be properly made only if moisture in the form of condensate is actually removed from the coolers. Care should be taken to make sure that the discharge temperature and pressure used is taken at or near the outlet of the cooler. If no aftercooler is installed the discharge temperature and pressure at or near the outlet of the intercooler should be used in the calculation outlined above.

11 *Indicated Horsepower.* The indicated horsepower for each end of the cylinder is found by using the formula:

$$\text{I.hp.} = \frac{PLAN}{33,000}$$

where P represents the mean effective pressure in pounds per square inch, L the length of the stroke in feet, A the area in square inches of the piston less the area of the piston rod, if any, and N the number of revolutions per minute. The total horsepower of the cylinder is the sum of the horsepower developed in the two ends.

11a *The Mean Effective Pressure* should be found by dividing the area of the indicator diagram in square inches as determined with a planimeter by the length of the diagram in inches, and multiplying the quotient by the average scale of the indicator spring. If a planimeter is not available, the approximate mean effective pressure may be determined by finding the average height of the diagram in inches as obtained by averaging a suitable number or ordinates, at least twenty, measured between the lines of the forward and return strokes, and then multiplying this average by the scale of the spring. The length of the indicator diagram is the measured distance along the atmospheric-pressure line between ordinates erected perpendicular to it and passing through the ends of the indicator diagram.

12 *The horsepower required to compress isothermally* the measured quantity of air at average speed of the compressor is found by multiplying the volume compressed per minute in cubic feet corrected to intake pressure and temperature by the absolute intake pressure in pounds per square foot and by the hyperbolic logarithm of the ratio of the absolute discharge pressure to the absolute intake pressure and dividing the product by 33,000.

13 *The Gross Horsepower* is the indicated horsepower in the steam or power cylinders in the case of a steam or internal-combustion-engine-driven compressor; the electrical horsepower multiplied by the motor efficiency in the case of a motor-driven compressor; and the brake horsepower delivered to the compressor shaft in the case of a belt-driven compressor. In the case of a compressor driven through belt, gear, etc., the power absorbed by the belt, gear, etc., must be taken into account.

14 *Electrical Horsepower.* The electrical horsepower of a motor is found by dividing the input at the terminals expressed in kilowatts by the constant 0.746. In the case of an alternating-current motor, the input determined, whether expressed in electrical horsepower or kilowatts, should be the total input. When the power for excitation or ventilation is taken directly from the compressor shaft, the total input is that indicated at the a.c. motor terminals; but if the motor efficiency as given does not account for the exciter input and exciter loss, the total electrical horsepower used in calculating the gross horsepower (Par. 13) is that indicated at the motor terminals less an equivalent current required to run the exciter.

15 *Volumetric Efficiency.* The volumetric efficiency is the ratio of the capacity of the compressor to displacement. The capacity is the actual amount of air or gas compressed and delivered, expressed in cubic feet per minute at intake temperature and pressure.

16 *Mechanical Efficiency.* The mechanical efficiency is the ratio of the air indicated horsepower to the indicated horsepower in the power cylinders in the case of a steam-driven or internal-combustion-engine-driven compressor, and to the brake horsepower delivered to the shaft in the case of a power-driven machine.

17 *Compression Efficiency.* The compression efficiency is the ratio of the work required to compress isothermally all the air or gas delivered by the compressor to the work done within the compressor cylinder, as shown by the indicator cards. The two factors involved in this ratio are defined in Pars. 12 and 11, respectively.

18 *Overall Efficiency.* The overall efficiency is the product of the compression efficiency and the mechanical efficiency.

THE DATA AND RESULTS

19 The data and results should be reported in accordance with the tables given herewith, adding lines for data not provided for or omitting those not required, as may conform to the purposes of the test. Unless otherwise indicated, the items should be the averages of all observations.

Table 1 constitutes the data and results applying to the compressing element and Tables 2, 3 and 4 the data and results applying to the driving element for motor, steam-engine and internal-combustion-engine drive, respectively. In reporting a test Table 1 should be combined with its appropriate driving-element table, the two being thrown together to form one complete table. The items of Tables 1, 2, 3 and 4 are so numbered as to indicate how this may be done most conveniently.

TABLE 1 DATA AND RESULTS OF TEST ON POWER-DRIVEN DISPLACEMENT AIR COMPRESSOR

COMPRESSING ELEMENT

(*A.S.M.E. Code of 1923*)

GENERAL INFORMATION

(1) Date of test..

(2) Location..

(3) Owner..

(4) Builder..

(5) Test conducted by..

(6) Object of test..

DESCRIPTION, DIMENSIONS, ETC., OF COMPRESSOR

(7) Type of compressor (single or multiple stage, and kind of gas)........

(8) Type of compressor valves..

(9) Method of driving compressor..

(10) Method of volume control..

(11) Rated discharge pressure..........................lb. per sq. in

(12) Rated speed..r.p.m.

(13) Rated displacement..............................cu. ft. per min.

(14) Rated output expressed in volume (air or gas at intake pressure and temperature).................................cu. ft. per min.

(15) Type of intercoolers and aftercooler..................................

		1st inter-cooler	2nd inter-cooler	3rd inter-cooler
(16)	Area of water-cooled surface, sq. ft...... See Par. 5	......	......	......
		1st stage	2nd stage	3rd stage
(17)	Diameter of compressor cylinders, in..	......	......	......
(18)	Stroke of pistons, ft..................	......	......	......
(19)	Diameter of piston rods or tail rods, in...	......	......	......
(20)	Clearance in terms of piston displacement, per cent...........	1st stage	2nd stage	3rd stage
	(a) Clearance, head end.......	....	....	....
	(b) Clearance, crank end......	....	....	....
	(c) Clearance, average........	....	....	....
(21)	Air cylinder ratio based on piston displacement:			
	(a) 1st stage to 2nd stage......	....	....	....
	(b) 2nd stage to 3rd stage......	....	....	....
	(c) Total (1st stage to final stage)....................	....	....	....
(22)	Horsepower constant, air cylinder:	1st stage	2nd stage	3rd stage
	(a) Head end (stroke × net piston area ÷ 33,000)........	....	....	....
	(b) Crank end (stroke × net piston area ÷ 33,000)........	....	....	....
(23)	Area of compressor cylinder jacketed surface..................	1st stage sq. ft.	2nd stage sq. ft.	3rd stage sq. ft.
(24)	Length and cross-sectional area, intake pipe..................	ft.	ft.	ft.
(25)	Diameter of final discharge pipe ..	in.	in.	in.

DESCRIPTION, DIMENSIONS, ETC., OF COMPRESSOR DRIVING ELEMENT

(See Tables 2, 3 or 4)

TEST DATA AND RESULTS

(40) Duration of test..hr.

Average Pressures

(41) Barometric pressure................................in. of mercury

(a) Corresponding absolute pressure...............lb. per sq. in.

(42) Pressure by gage at intake near cylinder..............lb. per sq. in.

(a) Corresponding absolute pressure...............lb. per sq. in.

(b) Maximum pressure above or below atmosphere by intake-pipe diagram .... lb. per sq. in.
(c) Minimum pressure above or below atmosphere by intake-pipe diagram near cylinders. (See Par. 4d) .... lb. per sq. in.

(43) Pressure above atmosphere in discharge pipe near high-pressure cylinder by gage .... lb. per sq. in.
(a) Corresponding absolute pressure .... lb. per sq. in.
(b) Maximum pressure above atmosphere, discharge pipe diagram near high-pressure cylinder .... lb. per sq. in.
(c) Minimum pressure above atmosphere, discharge pipe diagram near high-pressure cylinder. (See Par. 4d .... lb. per sq. in.

(44) Pressure in 1st intercooler by gage .... lb. per sq. in. (See Par. 4d)

(45) Pressure in 2nd intercooler by gage .... lb. per sq. in. (See Par. 4d)

Average Temperatures

(50) Engine-room temperature .... deg. fahr.
(51) Temperature of air or gas near intake, dry-bulb .... deg. fahr.
(52) Temperature of air or gas near intake, wet-bulb .... deg. fahr.

		1st cyl.	2d cyl.	3d cyl.
(53)	Temperature of air or gas in suction port, deg. fahr.	....	....	....
(54)	Temperature of air or gas in discharge port, deg. fahr.	....	....	....
(55)	Temperature of jacket cooling-water inlet, deg. fahr.	....	....	....
(56)	Temperature of jacket cooling-water outlet, deg. fahr.	....	....	....

		1st cooler	2d cooler	inter-cooler
(57)	Temperature of cooler circulating water inlet, deg. fahr.	....	....	....
(58)	Temperature of cooler circulating water outlet, deg. fahr.	....	....	....

(59) Temperature of air or gas in gaging tank at upstream side of orifice .... deg. fahr.

Total Quantities

(65) Relative humidity of air or gas at intake of compressor (use Smithsonian Tables) .... per cent.
(66) Air compressed and delivered to line .... lb. (See Pars. 4a and 4b)
(67) Air or gas compressed and delivered to line expressed in cu. ft. at intake pressure and temperature .... cu. ft. (See Pars. 10 and 10a)

		1st cyl.	2d cyl.	3d cyl.
(68)	Cooling water supplied jackets, lb.	....	....	....

		1st stage	2d stage	after cooler
(69)	Cooling water supplied coolers, lb.	....	....	....

Unit Quantities

(76) Volume of air or gas at intake pressure and temperature compressed and delivered per minute [Item 67 ÷ (60 × Item 40)] .... cu. ft.

		1st cyl.	2d cyl.	3d cyl.
(77)	Cooling water supplied jackets, lb. or gal. per min. [Item 68 ÷ (60 × Item 40)]	....	....	....

		1st stage	2d stage	after coolor
(78)	Cooling water supplied intercoolers, lb. or gal. per min. [Item 69 ÷ (60 × Item 40)]	....	....	....

Speed

(82) Total number of revolutions as shown by compressor counter ....
(83) Revolutions per minute [Item 82 ÷ (60 × Item 40)] .... r.p.m.
(84) Average piston speed .... ft. per min.

Power

(85) Indicated horsepower of compressor cylinders, whole compressor .... i.hp.
(86) Low-pressure compressor cylinder, horsepower:
Crank end .... i.hp.
Head end .... i.hp.
(87) Intermediate-pressure compressor cylinder horsepower:
Crank end .... i.hp.
Head end .... i.hp.
(88) High-pressure compressor cylinder horsepower:
Crank end .... i.hp.
Head end .... i.hp.
(89) Friction horsepower [Item 101 (Table 2) or 90 (Table 3)—Item 85] .... i.hp.

Power Input

(See Tables 2, 3 or 4)

Economy Results

(102) Gross horsepower per cu. ft. of air or gas delivered per min. at intake pressure and temperature (See Par. 13) .... hp.
(103) Electrical horsepower per cu. ft. of air of gas delivered per min. at intake pressure and temperature (See Par. 14) .... hp.
(104) Indicated horsepower in compressor cylinder per cu. ft. of air or gas delivered per min. at intake pressure and temperature (Item 85 ÷ Item 76) .... hp.

Efficiency Results

(109) Horsepower required to compress isothermally measured quantity of air or gas at average speed of compressor during test (See Par. 12) .... hp.
(110) Volumetric efficiency (See Par. 15) .... per cent
(111) Compression efficiency (See Par. 17) .... per cent
(112) Mechanical efficiency (See Par. 16) .... per cent
(113) Overall efficiency (See Par. 18) .... per cent

TABLE 2 ADDITIONAL ITEMS APPLYING ONLY WHEN THE DRIVING ELEMENT IS AN ELECTRIC MOTOR

SURVEY OF ENGINEERING PROGRESS

A Review of Attainment in Mechanical Engineering and Related Fields

Experiences on Evaporators with Heat Pumps

By E. Wirth

THE theoretical bases of evaporation with the heat pump are now fairly well known, but the process itself is still in the early stages of development, notwithstanding the fact that a good many plants have been in operation for a number of years. Up to quite recently data were available only on installations handling liquids with a low boiling point, but today we have other data on the heavier liquids.

The power consumption in the vapor-compression process is determined by the pressure ratio between the vapor-compression chamber and the heating chamber of the evaporator. A part of this pressure difference is consumed by what might be called "dead" temperature head, determined by the rise of the boiling point of the liquid because of the presence of dissolved matter therein. This has been pointed out already by Josse, Fluegel and Schreber.

Schreber considers it sufficiently precise to calculate the rise of the boiling point from the content of dissolved matter in the liquid. The writer, however, holds experimental determination to be more reliable, especially as once in his own practice he was unable to obtain proper performance in an evaporator which he built, because the liquid, with constant specific gravity, showed a variation in boiling point as high as 2 deg. cent. This has been confirmed by tests extending over a considerable period of time and without apparent errors in measurement.

The data obtained by direct measurement (Fig. 1) do not show any irregular variations, but produce, in accordance with the specific gravity of the solutions, points lying along two parallel lines, which would indicate the upper and lower limits of boiling. In the case of the glycerine solution, the greatest variation of the boiling point is 2 deg. cent., equivalent to 40 per cent with a total temperature head of 5 deg. cent. This is sufficient to cut in half the performance of the evaporator and shift the compressor into the unstable region of "pumping."

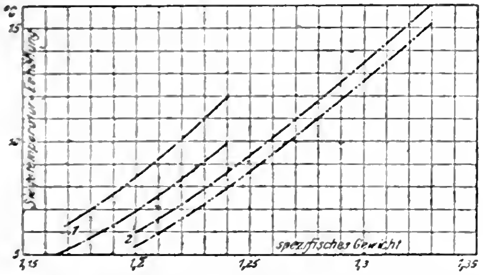

FIG. 1 BOILING-POINT CURVES OF VARIOUS LYES

(*Siedetemperatur-Erhoehung* = rise of boiling point; *Spezifisches Gewicht* = specific gravity.)

Fig. 1 shows not only the variability of the boiling point but also its location as compared with that of pure water. As shown by the curves, the mother liquids can have boiling points 10 deg. cent. (18 deg. fahr.) or more in excess of water, which may make entirely impossible the application of the process. This also shows that evaporator performances of 40 to 85 kg. (88 to 187 lb.) per hp-hr. which have been attained occasionally can be secured only under exceptionally favorable conditions and must not be considered as being possible in general practice.

Useful Temperature Head

In order to show more clearly the movement of the heat the author recommends replacing in the equation for the coefficient of heat transmission $\frac{1}{k} = \frac{1}{\alpha_1} + \frac{1}{\alpha_2} + \frac{\delta}{\lambda}$ the coefficients of heat flow and heat transfer by their reciprocal resistances—

$\frac{1}{k}$ = w = resistance of 1 sq. m. of area of heating element per deg. cent. difference of temperature per hour

$\frac{1}{\alpha_1}$ = w_1 = partial resistance on the condensation side

$\frac{1}{\alpha_2}$ = w_2 = partial resistance on the evaporator side

$\frac{\delta}{\lambda}$ = w_3 = partial resistance of the heater wall.

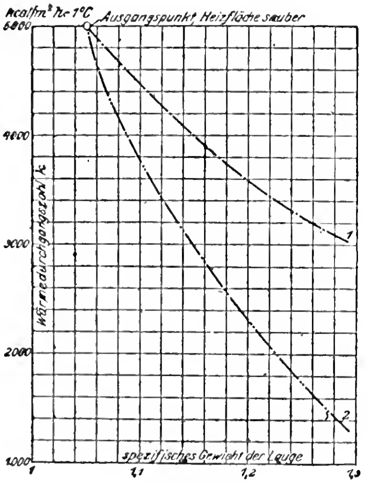

FIG. 2 SULPHITE LYE

(*Ausgangspunkt, Heizflaeche sauber* = starting point, surface of heating elements clean; *Waermedurchgangszahl* = coefficient of heat transmission; *spezifisches Gewicht der Lauge* = specific gravity of the salt solution.)

With this done the total resistance is $w = w_1 + w_2 + w_3$, and the total heat flow is expressed by the equation $Q = \Delta t/w$, similar to the formula for current, $i = e/w$, in electrical engineering.

The partial resistance on the evaporator side may be materially increased by the formation of solid deposits separating out of the mother liquid.

In a certain test there were used in an evaporator first chemically pure non-corrosive sulphite lye and then unpurified lye of similar material, with specific gravities up to 1.3. The heat-transfer values are shown in Fig. 2. From this it would appear that with increasing concentration the heat transfer in the case of pure salt lye decreases, but that the difference in heat transfer is very much greater with unpurified lyes because of an increasing formation of a crust over the heating elements. Notwithstanding the fact that the sediment formation at the end of a 10-hr. run appeared

still to be comparatively light and attacked only a part of the heating element. At the end of the test the coefficient of heat transmission was 3000 for the pure salt solution and 1250 for the impure lye. That the formation of deposits produces unfavorable results in so far as the effectiveness of evaporators is concerned, has been, of course, known for a long time, but it is always assumed that this would apply to very long periods of operation and that cleaning of the tubes would afford a relief for a considerable length of time. The present tests would indicate that this is not always so.

In addition to the maintenance of the walls of the evaporator in a clean condition, the lively movement of liquid in the proximity of the heater walls has also a great influence on partial resistance to heat flow.

The partial resistance on the side where condensation takes place is materially dependent on the presence of non-condensable gases in the steam. For example, the author found by measurement on a vacuum evaporator which was not quite tight that even 3.5 parts per thousand by weight of air in the steam on the condenser outlet side reduces the coefficients of heat transfer from 2140 to 1410. Josse found in the case of a surface condenser that $^1/_2$ of one per cent by weight of air in steam cut the heat transfer as compared with air-free steam in half. It is therefore important to keep the heating chambers as free from air as possible. In the vapor-compressor even a small admixture of air reduces evaporation very rapidly. That not only air but also other gases can affect the heat transfer materially is shown by Fig. 3. The vapor compressor there is operating with the liquid which gives up particles which are, however, soluble in water. Notwithstanding a uniform concentration, uniformly clean surfaces of the heating elements and absence of air, the performance varies to an extraordinary extent, which indicates an unstable condition on the condensation side. Apparently the gas produces an insulating layer on the walls of the heating elements on the condensation side, and this insulating layer upsets all calculations as regards performance.

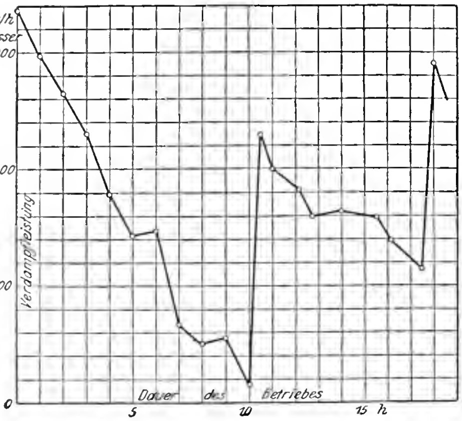

Fig. 3 Curves Showing the Irregularity of Operation of an Evaporator Due to Disturbance
(Other than the presence of air arising on the condensation side)
(*Wasser* = water; *Verdampfleistung* = evaporation output; *Dauer des Betriebes* = duration of run.)

The partial resistance of the metal walls is the element which admits of the most reliable calculation. It is of importance only in cast-iron evaporators or in evaporators where the resistances w_1 and w_2 are very small. Where chemical influences do not make the employment of other materials imperative, iron is usually suitable for heating elements. If, however, the resistances w_1 and w_2 can be maintained very small, it is of benefit to employ a metal wall of good heat conductivity.

In general, in computing the temperature fall across the heater element, it is better not to assume rigid coefficients of heat transmission, but to consider the character of heat flow in each case and the previous experience available in this connection.

Superheating of Heating Steam

This has acquired a considerable importance since the employment of compressors which produce superheated steam without any extra cooling. The first experience with compressors proved to be quite difficult, because of the presence of steam superheating, which was generally considered as being harmful to proper heat transfer. On the other hand, however, Classen has pointed out that the heat transfer in an evaporator with superheated steam is, all other conditions being equal, greater than with saturated steam. The experience of the writer would indicate that this is entirely possible, and, on the whole, the influence of superheating of steam need not be always quite as unfavorable as would seem to be indicated by some previous experiments (Ombeck).

Foaming of the liquid, which increases with rise of temperature, may cause trouble, and such means of combating foaming as are known are apt to cause increased pressure losses in the suction piping.

Since a high level of liquid over the heating surface is undesirable from the point of view of evaporating output because it increases the boiling temperature, attempts have been frequently made to combat its influences by the employment of spray devices. This cannot, however, be applied when the liquid is of such character as to form solid deposits. The Piccard process, in which the heating and evaporation are carried out separately and which has been applied as early as 1878 in Switzerland, is fundamentally simple and good, but increases the pressure conditions in the compressor.

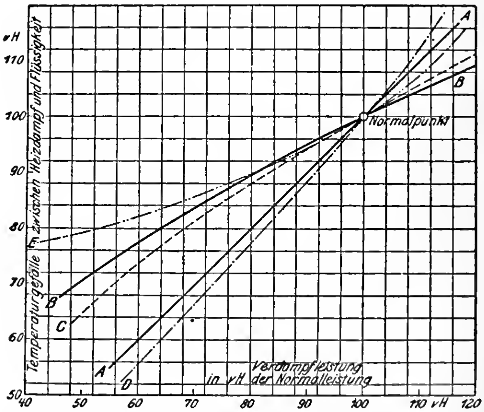

Fig. 4 Characteristic Curves of Various Evaporators
(Ordinates: Temperature head between heating steam and liquid; *vH* = per cent; Abscissae: Evaporation output in per cent of normal output; *Normalpunkt* = point of normal performance.)

The Characteristic Curve of the Evaporator

Even with clean surfaces the heat transfer in an evaporator is not of constant magnitude but depends on the type of evaporator, pressure conditions, character of the liquid, and other influences. In the design of the apparatus it is therefore a good plan to plot first the characteristic curve for the evaporator by plotting the evaporator output against the corresponding temperature differences. In order to obtain a general basis for purposes of comparison, there have been used in the curves of Fig. 4 not the actual values but comparative values based on an output of 100 per cent at a temperature difference of 100 per cent.

For purposes of comparison two theoretical characteristic curves have been plotted: *A*, with an entirely uniform rate of heat transfer under which condition the output varies according to a straight-line law with the temperature differences; and *B*, with a rate of transfer which varies in proportion to the temperature fall under which condition the characteristic curve appears as a parabola. Curves *C*, *D* and *E* have been derived from tests on large evaporators and the curve *C* was taken from an evaporator of conventional design with vertical tubes in the heat chamber. It approaches a parabola and the rate of heat transfer appears,

therefore, to be approximately proportional to the temperature fall. Curve *D* is taken from tests by Professor Stodola on a Kummler and Matter compressor, and curve *E* on an evaporator operating with after-evaporation, and therefore one in which the output depends very strongly on the temperature head.

The Compressor

For larger outputs on one hand and for higher vacua on the other, only centrifugal compressors can be commercially used owing to the large amounts of steam that have to be handled. Such compressors have a lower efficiency than reciprocating compressors, but they have smaller dimensions and the further advantage that they give oil-free condensate and have and can be coupled to the driving machinery more conveniently.

The centrifugal compressor has a characteristic curve showing that with decrease of volume of steam handled the rise of pressure increases until it reaches a maximum, and then, if the volume of steam continues to decrease, begins to fall off, the compressor gradually passing into the unstable region of "pumping." The compressor operation can be expressed in a percentage curve similar to that used in the case of the evaporator, in which case instead of rise of pressure may be used rise of temperature referred to saturated steam. Fig. 5 gives such a characteristic curve for constant speed in revolutions and constant pressure in the case of a standard Zoelly centrifugal steam condenser having an output of about 1700 cu. m. (60,000 cu. ft.) per hr. and a pressure rise from 1 to 1.7 atmos, abs. The curve *v1* is the characteristic curve obtained without cooling by water injection and curve *v2* with cooling in stages by water injection. Although with cooling by water injection the saturated-steam temperature was about 10 per cent higher, in this particular case cooling did not lead to higher output but only to greater power consumption. Curves *v3* and *v4* give the steam in kilograms per kilowatt-hour of the energy supplied to the driving motor. With decrease of output the evaporation per kilowatt-hour falls off materially, and should this fall below the critical volume it would become necessary to resort to throttling, which would make the efficiency still lower. It would appear, therefore, that for vapor compressors the problem is to arrange matters so as to work always with the compressor at its normal output. (*Zeitschrift des Vereines deutscher Ingenieure*, vol. 65, no. 46, Nov. 12, 1921, pp. 1183-1186, *pe*)

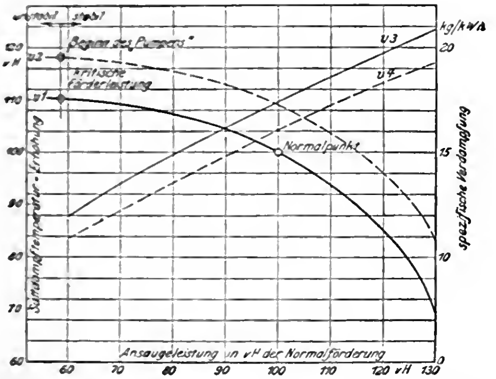

FIG. 5 CHARACTERISTIC CURVES FOR A CENTRIFUGAL COMPRESSOR

(*unstabil-stabil* = unstable-stable; *Beginn des Pumpens* = beginning of "pumping;" *vH* = per cent; *Kritische Foerderleistung* = critical output; *Normalpunkt* = point of normal performance; *spezifische Verdampfung* = specific evaporation; *Ansaugeleistung in vH der Normalfoerderung* = suction output in per cent of normal.)

The following emergency methods for obtaining extra cooling on aeroplane engines are recommended by the Air Board, Ottawa, Canada (Technical Memorandum, No. 12): (1) Addition of a lip to the front of radiator (applicable only to some machines, particularly tractor type); (2) Spiral air deflectors in the open end of the tube (not to be used except for emergency purposes); (3) Removal of cowling (reduces efficiency of engine).

Short Abstracts of the Month

AERONAUTICS

Dornier Dragon Fly Flying Boat. Description of a new machine built at Rorschach on the Swiss side of Lake Constance by the Dornier Co., a subsidiary of the German Zeppelin Works.

Under the characteristic features may be mentioned the air-flow floats projecting from the sides of the hull, which take the place of the wing-tip floats and have the advantage of contributing to the lift instead of adding to the resistance of the machine.

The machine is built almost entirely of duralumin, which is employed also for the wings and wing coverings. The wings, it may be stated, are of the semi-cantilever type without dihedral or sweepback. They are built up in three sections and are made to fold back, and it is stated that with the wings folded the machine maneuvers on the water as easily as a motor boat.

The outer wing sections are braced to the hull by a pair of streamline struts on each side. When the wings are folded back the front struts are disconnected at the attachment to the hull and are secured to a lug in the lower extremities of the rear struts.

The floating operation can be accomplished in about $1\frac{1}{2}$ min. and it takes only about 1 min. longer to extend the wings. Both operations can be carried out while the boat is on the water and it is claimed that once erected the wings do not require any truing up.

With a 50- to 60-hp. five-cylinder radial air-cooled engine, three passengers on board and fuel for one hour's flight, the machine lifts from the water in about 30 sec. (*Flight*, vol. 13, no. 42/669, Oct. 20, 1921, pp. 685-686, 7 figs., *d*)

AIR MACHINERY (See also Testing and Measurements)

Propeller Blowers

Propeller Blowers for Forced-Draft Furnaces, Werner Mueller. General discussion on the subject of propeller-type blowers as distinguished from centrifugal blowers, and description of some of the German types.

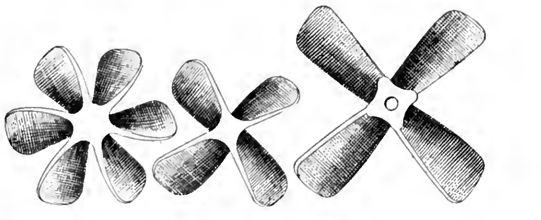

Fig. 1 Aluminum-Alloy Propeller for Use in Blowers

The design of propeller blowers has been materially affected by information gained from tests on aircraft propellers, as the same aerodynamic laws apply to both, even though the purpose of the two is different.

The essential characteristic of the propeller is the profile with a large cross-section of blade, thick rounded-off entrance edge and smoothly-drawn-out exit edge. The pressure side of the blade is concave and the suction side convex, with the constant curvature so designed as to attain a flow of stream lines as far as possible free of turbulence. Figs. 2 and 3 show the difference in the appearance of the air flow between the correctly selected turbulence-free propeller blade and the common, more or less bent, thin sheet-iron blade. Attention is called in this latter type to the turbulent formations on the suction side, which act as a brake on the wheel and thus create a parasite power consumption. With a blade of proper shape these back eddies do not seem to occur.

In addition to the shape of the blade, the design of the blower housing materially affects its efficiency. The propeller screw acts on the surrounding medium by forcing it ahead acceleratingly, and only to a very small extent does a direct transformation into pressure

take place. Because of this, the velocity to the rear of the propeller wheel is greater than that ahead of it, and in order to secure a flow free from turbulence through the housing this latter must have a smaller cross-section to the rear of the propeller than it does in front of it. (Compare Figs. 4 and 5.) Bendemann shows that theoretically the smallest cross-section should be equal to one-half of the propeller-circle area. With such an arrangement there occurs a clearly defined tightening of the flow lines which decreases in increase in counter pressure but never disappears entirely. The remaining excess in flow velocity can be converted into pressure only by the employment of a conical intermediary piece known as a "diffuser." The diffuser therefore plays the same part in a propeller blower as the spiral casing in a centrifugal blower. The relation between the theoretically smallest aerial flow corresponding to the "equivalent nozzle" and the area of the propeller circle gives a valuable basis for the calculation of blowers for given outputs.

Fig. 5 Incorrect Propeller Housing, Creating Considerable Turbulence in the Rear

As regards the most advantageous speed in revolutions, it is stated that for small blowers 2800 and for larger blowers up to 1450 r.p.m. are best, particularly as they correspond to the usual speeds of polyphase motors, thus permitting direct coupling. Such blowers as the Foege are therefore always built for direct coupling and not for belt drive, as the latter at these high speeds of revolution is not sufficiently reliable. Direct drive through steam or air turbines could also be used.

The propeller proper (Fig. 1) is a high-grade aluminum alloy casting with a tensile strength of 18 to 20 kg. per sq. mm. (26,000 to 28,500 lb. per. sq. in.) and is cast from patterns reproducing carefully-tested-out wooden propellers. It is claimed that these propellers require only a very small amount of machinery, and, in particular, that they do not have to be tested for strength under speeds in excess of operating, as the dimensions are so generously proportioned that there is no danger of their bursting under the action of centrifugal stresses. On the other hand, they must be very carefully balanced, as otherwise heating will develop. Also the boring for the shaft should be done very carefully in order that every blade will travel in the exact path of the preceding blade. Ball bearings exclusively are used, and in addition to a double-row shaft ball bearing a thrust ball bearing is employed.

The article describes in considerable detail some of the features of design and installation of the blowers and also gives data on propeller-blower operation.

As to the latter, Fig. 6, in particular, shows that the power consumption of a propeller blower is very nearly the same over the entire cross-section of the piping and that it proportionately falls off as the volume of air increases. It is also practically independent of the resistances which may be created in the piping by the use of throttling valves or similar devices. On the other hand, in centrifugal blowers the power consumption is very materially affected by the presence of resistances, and becomes a maximum with an entirely open pipe cross-section. This means that the motor driving a centrifugal blower has to be made of very generous proportions in order not to be overloaded when all the resistances in the pipe are eliminated; it also means that with certain types of drive, as, for example, the steam turbine, there is a danger that with the passage entirely closed the unit might run away, and special means have to be taken to prevent this dangerous possibility. All these difficulties are eliminated in the propeller blower as the driving motor has to deliver only the predetermined amount of power suitable for continuous operation.

As regards pressure as a function of the pipe cross-section, Fig. 7 gives a straight line, which shows a practically proportional variation. Maximum pressure is obtained with the damper fully closed, while with the damper fully open the entire pressure appears as velocity. Such a mode of variation is particularly acceptable for use with piping, as the pressure produced by the blower increases with the increase of resistances. Contrariwise, in centrifugal blowers the pressure falls off with increase of resistance, which is much less desirable from a practical point of view.

Fig. 8 gives efficiency curves of the two types of blowers, showing that the peak values are about the same in both cases, but the general character of the curves is materially different. In centrifugal blowers the curve of efficiency reaches a clearly pronounced peak value and then rapidly falls off on both sides, which means that it is rather difficult to design a centrifugal blower which will efficiently take care of the variable local conditions of operation. This is much easier with the propeller blower as its curve is considerably flatter.

ENGINEERING MATERIALS

Stainless Steel for Turbine Blades

Some Engineering Uses of Stainless Steel. Stainless steel is an alloy steel containing from 12 to 14 per cent of chromium and about 0.5 to 0.6 per cent carbon. The present paper describes some experiments made with stainless steel in turbine blades, in particular experiments made in a turbine at the power station of one of the makers of this steel.

The machine selected for the test was a British Westinghouse impulse turbine rated at 2000 kw. and running at 3000 r.p.m.

The experimental blades were fitted to two of the wheels some time about June, 1920, and the wheels chosen were, respectively, the velocity wheel which constitutes the first stage of the turbine and is operated with steam at a high temperature, and wheel No. 8, which constitutes the last stage of the turbine and is fed with wet steam. Twelve of the existing blades were removed from wheel No. 8. Three were replaced by highly polished blades of stainless steel having beside them three blades of the same material in the unpolished condition, while on the opposite side of the wheel another triplet of unpolished stainless steel blades were inserted alongside of three new 5 per cent nickel-steel blades obtained from the builders of the turbine. In the velocity wheel 24 blades were replaced by 21 blades of stainless steel, three of them polished, and by three new blades of the 5 per cent nickel steel.

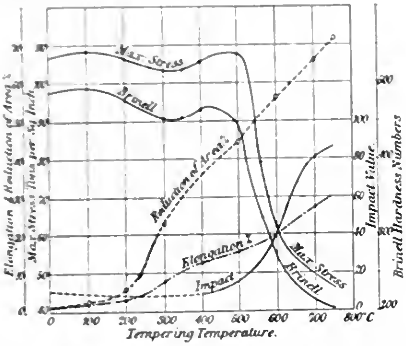

Fig. 10 Curves Showing Physical Properties of Stainless Steel after Heat Treatment

The turbines were opened up after having been in operation with the new blades for 3471 hr. It is claimed that the stainless-steel blade appeared to be totally unaffected by the work done and did not show either corrosion or appreciable erosion, while the nickel-steel blades inserted at the same time showed both, in particular along the inlet edges. The article refers also to the application of stainless steel to the rams of hydraulic pumps.

In a three-throw hydraulic pump built in Sheffield, rams of stainless steel and phosphor bronze were tried. It is said that the stainless-steel ram has maintained its original polish better and suffered less wear than the phosphor-bronze ram.

Stainless steel can be hardened and tempered similarly to carbon steel, but it is important to note that its change point is much higher, namely, at about 950 deg. cent.

Fig. 10 shows the variation in the properties of stainless steel as tempered at the various temperatures represented by the curves. For forging the temperature should be between 1150 and 900 deg. cent., though it is not impossible to work it below the latter limit. It can be electrically welded, but not with a smith's fire, as layers of chromium oxide form and prevent the union of the surfaces. (*Engineering*, vol. 2913, Oct. 28, 1921, pp. 592–594, 7 figs., *ec*)

Strength of Manila Rope, Ambrose H. Stang and Lory R. Strickenberg. Data of tensile tests of 368 specimens of manila rope. All the rope tested was three-strand, regular-lay type having diameters varying from $^1/_2$ in. to $4^1/_2$ in. An interesting feature of the test is the great consistency in results. The ropes showed, however, a continued varying modulus of elasticity and no well-defined proportional limit.

The following is given as a summary of the results obtained:

1 The average breaking load was found to be approximately a quadratic function of the diameter of the rope. It is expressed quite closely by the equation:

$$L = cd\ (d + 1)$$

in which L is the load in pounds, c is a constant equal to 5000, and d is the diameter of the rope in inches.

2 The ropes showed a continually varying modulus of elasticity and no well-defined proportional limit.

3 The number of yarns composing a rope may be expressed approximately by the equation:

$$N = kd\ (d + 0.4)$$

where N is the number of yarns, k is a constant equal to 50, and d is the diameter of the rope in inches.

4 The test results cover sufficient range and show such consistency that it is believed that the formulas deduced may be used safely for three-strand, regular-lay manila rope for sizes of rope between $^1/_2$ and $4^1/_2$ in. in diameter. (*Technologic Paper of the Bureau of Standards*, no. 198, Sept. 15, 1921, pp. 3–11, 5 figs., *e*)

INTERNAL-COMBUSTION ENGINEERING

An American Solid-Injection Diesel Engine

Worthington Airless-Injection Oil Engine. The writer uses the expression "airless injection" to indicate its difference from the air-blast injection of the Diesel engine, although the expressions "solid injection" and "mechanical injection" have hitherto been more common.

In the new Worthington engine fuel oil is delivered to the engine by a service pump operated by an eccentric on the crankshaft.

The engine is of the valveless two-cycle crosshead type with a separate compartment between the cylinder and the crankcase for scavenging air.

One of the distinguishing characteristics of this engine is the use of a divided, or two-part, combustion chamber. The function of this divided combustion chamber is to reduce explosive pressures and to create a condition of air turbulence in the main combustion chamber during the combustion period. Shortly before top dead center, fuel is injected through the spray valve in an atomized condition directly into the smaller of the two compartments, known as the "injection chamber," this being located above and directly in communication with the main combustion chamber or cylinder clearance space. Ignition of the fuel is from the heat of compression and the period of injection is so timed that the partial burning of the fuel charge in the injection chamber produces sufficient pressure to start the flow of the main part of the fuel charge down into the cylinder until the jet of gaseous oil and air from the injection chamber attains considerable velocity, producing a turbulent condition in the cylinder just as the piston starts on its downward stroke. This is accelerated by the downward motion of the piston.

Combustion then takes place in the lower chamber or cylinder, under conditions closely approximating the air-injection Diesel engine, the resultant expansion of gases driving the piston down on its power stroke, after which the cycle described above is again repeated. The pressure from the fuel pump is high, but lasts only during injection about 15 deg. of crank angle. It will be noted that the time and rate of combustion are independent of time and rate of pump injection.

One of the refinements of the Worthington engine consists in providing a scavenging-air connection on the base of the engine which may be piped to the outside of the engine room. By this means a supply of pure, fresh air may be had for scavenging purposes in places where the air of the engine room is charged with dust or explosive vapors.

The fuel-injection pump is of the unpacked type, and as will be seen from Fig. 11, is driven by an eccentric (17) mounted on the crankshaft. Each cylinder has a separate and independent pump, complete in all its details. By avoiding the use of packing from the pump plunger, danger of the plunger sticking is eliminated, and at the same time leakage past the plunger is considerably less than in the usual type of packed pump. The pump body (24) is made from a solid block of steel, designed and constructed with great care, and the plungers and valves are assembled in this body of a unit.

Actuation of the pump plunger is by the eccentric (17), the crosshead (19) engaging the tappet (21), which in turn pushes the plunger upward on its injection stroke, the plunger being returned to its at rest position by the spring as the eccentric passes its top position. The actual instant at which the pump plunger begins to move upward determines the instant of injection of oil into the injection chamber.

For control, a centrifugal governor is fitted, acting through a series of rods and levers to rock the control shaft (10). This shaft is turned eccentric at a point in line with each fuel-pump plunger, and a so-called "by-pass lever" (9), actuated at one end by the pump plunger, rests at the other end on the eccentric part of the control shaft through the medium of an adjustable set screw. As the end of the by-pass lever moves upward with the pump plunger the by-pass tappet (9) and the plunger (7), resting on the lever, will move upward also, closing the gap between its upper end and the suction or by-pass valve (2). When contact is established at this point the continued upward movement of the plunger will open the valve, permitting the oil to by-pass back to the fuel reservoir instead of being forced through the spray valve, and thus ending the injection or effective pump stroke. It will be seen that by rocking the control shaft (10) one way or the other from its normal running position, the instant of opening of the suction valve by the by-pass plunger may be retarded or advanced, thus increasing or decreasing the effective pump stroke and feeding more or less oil into the cylinder, according to the load requirements. Also, by regulation of the set screw in the end of the lever (9), the instant of by-pass opening for each cylinder may be individually adjusted for purposes of initial setting and load balancing. (*Motorship*, vol. 6, no. 11, pp. 872–875, 10 figs., *d*)

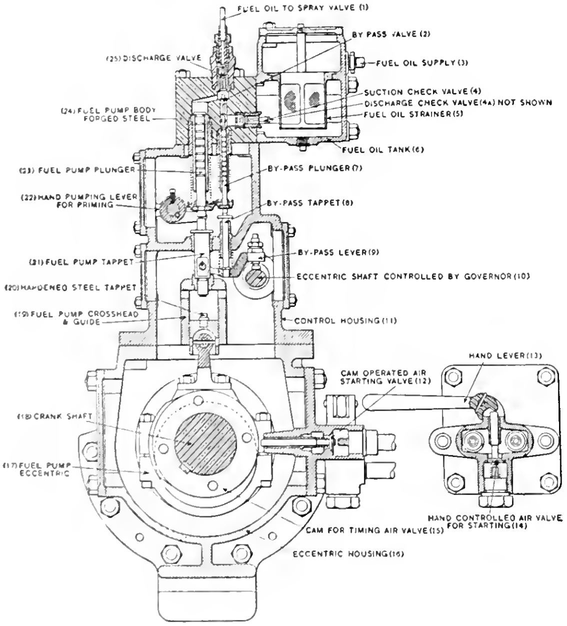

Fig. 11 Section of Worthington Engine Fuel Pump

Cooling-Water Systems for Stationary Internal-Combustion Engines, Edgar J. Kates, Mem.Am.Soc.M.E. Description of the various systems, beginning with the simple cooling tank and proceeding by gradual stages to the cooling towers of various types, overhead supply tanks, and finally the enclosed cooling system, which is the most modern development.

The principal feature of this latter is that the jacket water is recooled in pipe coils over which other water is showered or flowing. The only place where the engine water is exposed is at the visible outlet. Because of this the loss is negligible, practically no makeup water is required, and clean water may be used for jacket circulation while an inferior type is doing the actual cooling work.

Where there is a scarcity even of inferior water for cooling the pipe coils, an arrangement illustrated in the original article may be used. In this the raw water itself is in a basin below the pipes and pumped by a second pump over an open screen-type cooling tower, where it is recooled and ready to be used again over the pipe coils.

The system just described may seem elaborate and complicated, but it is not so in reality. Where the water available is of inferior character and scarce, as in the mining regions of western Texas, such systems afford the only satisfactory method known of cooling internal-combustion engines. It is said that one oil-pipe-line company has equipped all its plants with similar systems.

Reciprocating pumps are said to be preferable to centrifugal pumps for water-circulating systems, because of their greater reliability and uniformity of operation. (*Power*, vol. 54, no. 19, Nov. 8, 1921, pp. 710–713, 4 figs., *cd*)

LOCOMOTIVE ENGINEERING (See Power-Plant Engineering)

MACHINE DESIGN

The Control of Machines by Perforated Records, Emanuel Scheyer. General discussion of the process as applied to textile machinery, piano players, automatic typewriters, etc.

Perforated-paper-record control has been applied also to metal-working machinery, as, for example, in the automatic multiple-punching machines of Wm. Sellers & Co., described in some detail in the article.

The author proposes to apply a modified form of the Jacquard method of perforated-paper-record control to machine tools of the turret type. He states that a lathe equipped with this kind of control cannot compete with the ordinary cam-controlled automatic lathe within the proper field of work of the latter, but may be applied for handling work which is larger or more complicated than can be handled by cam-controlled machinery. The description of a proposed lathe with such a type of control is given in the original article. (*American Machinist*, vol. 55, no. 19, Nov. 10, 1921, pp. 743–747, 8 figs., *dA*)

MACHINE PARTS (See Machine Tools)

MACHINE TOOLS

Gray Co. Planer with Helical Gear Table Drive. Description of a new planer, one of the characteristic features of which is the use of involute helical gearing for driving the table.

Planers have heretofore been built with herringbone or helical gears for the first reduction, but the new Gray planer has helical gears throughout. The Gray company states that a train of planer gears having one or more pairs of spur gears cannot give the results which are obtained by the use of properly proportioned helical gears throughout, that is, from pulley-shaft pinion to table rack.

Helical gears produce end thrusts. Advantage is taken of this fact to cause the end thrust of the bull gear and its pinion to counteract the side thrust of the tools when cutting. Moreover, the diameters and helical angles of the remaining gears of the train are so proportioned that their end thrusts very largely balance one another. Bronze thrust collars, provided with forced lubrication, take the slight residual end thrusts. Particular attention is called to the helical table rack which is of unusual width of face, giving great strength. The helical rack is arranged so that the end thrust of the bull pinion, which amounts to about one-tenth of the driving force, opposes and compensates for the side thrust of the cutting tools when they are being fed away from the operating side of the machine, a condition which obtains at least 90 per cent of the time. As the tool pressure increases, the power required to drive the table and the resultant balancing thrust of the bull pinion also increase proportionately. This, it is said, equalizes the pressure and wear on the two sides of the V's, whereas with a rack of the spur form the pressure and wear are greater on one side of the V's than on the other, due to the side thrust

of the cutting tools. It also overcomes the tendency of the tools to push the table up the side of the V's.

To provide correct tool action, teeth of true involute form, cut by a generating process, are employed. In order to avoid interference and imperfect tooth forms, and to obtain great smoothness of action and stronger teeth, the pinion teeth are so cut that the greater part of the tooth face lies outside the pitch circle. The teeth have a low pressure angle, are cut full depth, and have a short arc of approach and long arc of recess, giving high efficiency, and greatly increasing the number of teeth in contact and the smoothness of action. The action of a tooth having a long arc of recess compared to one with a long arc of approach is analogous to the action of dragging the end of a pole behind you compared to pushing it ahead of you.

This design, it is said, also has the advantage of permitting the use of pinions of larger diameters and stronger tooth form without the disadvantage which attend the use of stubbed teeth, high pressure angles and low gear ratios. (*The Iron Age*, vol. 108, no. 22, Dec. 1, 1921, pp. 1417–1419, 4 figs., *d*)

MECHANICS

Stress Coefficient for Large Horizontal Pipes, Jas. M. Paris. A new method of calculating stresses wherein a general case of the pipe is analyzed by breaking it up into a number of fixed elementary cases, and elastic analysis for each of these is worked out, the results being then combined by simple addition in proportion as the several elementary loadings are contained in the actual loading of any given particular case.

Essentially, for general loads on a large circular pipe, it is assumed that the deflection along the vertical diameter takes place at one end. Considering the half-pipe to one side of this diameter, its one end is assumed fixed and the half-pipe treated as a cantilever beam; the very end is imagined to deflect under the applied external loads and then brought back to its original direction by a moment applied through M_T, and back to its original position by a horizontal force H_T.

From the elastic-arch theory, using Maxwell's theory of reciprocal deflections, equations are deduced for the unknown reactions M and H. These reactions contain m, which is the general expression for the cantilever moment of the external forces on either half of the pipe, and by substituting for m in the equations its actual value for any loading, values of M_T, H_T, etc., are found for that loading. When this has been done for various simple and elementary loadings, any number of them may be combined, and by addition of the separate values the resultant value of H_T or M_T may be found.

Several interesting examples of the application of the method are given in the original article. (*Engineering News-Record*, vol. 87, no. 19, Nov. 10, 1921, pp. 768–771, 3 figs., *tA*)

The Whirling Speeds of a Loaded Shaft Supported in Three Bearings, Prof. H. H. Jeffcott. An extensive paper dealing analytically with the first and higher whirling speeds of a shaft supported in three bearings loaded in any manner and of sections varying from place to place along the length of the shaft. In the general case the shaft is supposed to change in diameter at various sections along its length and to be of uniform size between such sections. Other assumptions are made, in particular, that the shaft is assumed to carry at various places along it a series of loads each of which is balanced. The bearings are assumed to act as free supports and not to fix the direction of the shaft any extent for the small deflections contemplated.

In solving the general problem of a number of loads on the shaft, the author resorts to the use of a principle originally enunciated by Bresse, which may be stated as follows: The displacement of any point by reason of the deflection of the shaft is the resultant of the displacements which would be produced if one supposes all the external known forces to act separately, and one after the other. Thus, the shaft may be considered as supported at each end under the action of the given load acting downward, and also under the action of the supporting force at the intermediate bearing acting upward. The result of the action of these two systems of forces is to make the deflection zero at the intermediate bearing.

From this the author derives a number of equations for the deflections and slopes at any given point of each span due to the system of loads and for the total deflection and slope due to all the loads acting simultaneously. A numerical example to illustrate this principle is given, as well as equations determining deflections and slope under the centrifugal loading considered.

One simple case of oscillatory vibration for a three-bearing shaft is considered and the speed of a simple oscillatory vibration determined, likewise the ratio of oscillatory speed to normal whirl speed. (*The London, Edinburgh and Dublin Philosophical Magazine and Journal of Science*, vol. 42, no. 251, Nov. 1921, pp. 635–668, 5 figs., *tm*A)

MEASUREMENTS AND TESTS (See Engineering Materials)

MILITARY ENGINEERING (See also Aeronautics)

Aircraft versus Dreadnaughts, Hon. Frederick C. Hicks. General discussion of the part of aircraft-bombing tests of seacraft which closed with the sinking of the *Ostfriesland*, presented in a speech in the House of Rrepresentatives, of which the author is a member.

The author tries to present both sides of the question and points out that as long as gravity is the force utilized to carry the bomb to the target, an aeroplane will always have to be within a certain fairly limited zone over the ship which it is attacking.

On the other hand, however, the torpedo-carrying plane may be expected in the near future to become part of the aircraft outfit, and the torpedo bids fair to be the most deadly weapon carried by aircraft.

As regards the effectiveness of bombs which would simply hit the superstructure, it is admitted that they smash things badly, but it is believed that their destructive effect is largely local. In fact, what happened on the destroyer *Manly* in 1918 when a number of depth charges exploded on her afterdeck, it would appear that bombing on decks would not materially affect the men below, though of course it is always possible that a bomb might jam the rudder, derange the alignment of the shafts, or cause other damage that would affect the steaming or maneuvering capacity of the ship.

Of the lessons taught by the demonstration the following might be cited.

1 Aircraft is a weapon of such great value as to warrant the immediate expansion of the service; among other things, by the construction of aeroplane-carrier vessels of large size and great speed. No need in the United States Army is said to equal today that for ships of this type, of which there is none either built, building or authorized.

2 For coast defense, aeroplanes are indispensable and are weapons of the first magnitude.

3 Heavy bombs should be employed from the very outset of the attack, except in special cases.

4 Close-by, under-water hits are more deadly than direct hits on the decks or hits on the surface of the water. Under-water explosions can be obtained by delayed fuse action, and, as a matter of fact, the heavy bombs had a delayed action of $1^{1}/_{5}$ sec.

5 There must be a change in the design of surface craft with increased watertight integrity, and war vessels must be provided with better means of protection from both explosive and gas bombs.

At the same time the speaker pointed out that aviation is in its infancy, while battleship construction represents the advanced thought and skill of a century. The margin of development undoubtedly lies with a new service. (*Journal of the United States Artillery*, vol. 55, no. 5/183, Nov. 1921, pp. 390–399, *g*)

MOTOR-CAR ENGINEERING

British 200-Mile Rate and Its Lessons, "A Competitor." One of the striking features of the British 200-mile race limited to cars of 1500 cu. cm. was the high crankshaft speed employed and the reliability of the multi-valve head. Speeds were as high as 4000 r.p.m. (*The Autocar*, vol. 47, no. 1359, Nov. 5, 1921, pp. 864–865, *g*)

Progress in Light Cars, "Runabout." The success of some small cars in the Scottish six-day trial and their ability to handle all requirements of general travel have led to what appears to be

a stampede to produce cheaper and lighter cars, and a good many of them appear to be quite satisfactory.

Some of these cars like the 8-hp. air-cooled Rover have given apparently excellent satisfaction. It is, however, stated that air cooling is still in its infancy and, for example, the Rover has to be decarbonized about every 800 miles. Also the twin-cylinder engine is apt to be somewhat noisy. Improvement is, however, being rapidly made in both directions.

As regards performance, it is stated, for example, that a speed Hillman does 45 m.p.h. uphill on middle gear and is very economical both in oil and fuel consumption.

An important feature in this connection is that not only the smaller firms but also some of the leading concerns are becoming effectively interested in the production of small cars.

As regards the economy of the small cars, it is stated that 35 miles per gallon is common and as high as 50 miles has been attained, together with 1500 miles per gallon of oil. At the same time, however, it should be remembered that the cost of running a small car is very much higher in England than it is in America. In the first place, a car of the Hillman type costs somewhere around £400, or roughly $1500, although 8-hp. models are available in the market at prices as low for British conditions as £250 ($950). (*The Autocar*, vol. 47, no. 1359, Nov. 5, 1921, pp. 879–882, 6 figs., *g*)

General Survey of the Mechanical Features of British Automobiles for 1922. An article based on the features shown at the Annual Automobile Exhibition in London. In the broadest sense, the typical car of 1922 as exemplified by the show meets the following specifications: Four-cylinder water-cooled block engine with side valves; magneto ignition; cone clutch; four-speed side-chain gear box; spiral bevel final drive; semi-elliptic springs; wire wheels.

There is, however, a strong tendency toward the use of overhead valves, detachable cylinder head, single-plate clutch, disk wheels and possibly four-wheel brakes.

The four-cylinder engines still hold the leading position; detachable cylinder heads are becoming common practice, and the joints are being so arranged that the gasket has to be compression type only, while separate joints, sometimes in the exterior of the engine, attend to the necessary water circulation between cylinder jacket and head jacket.

Water cooling remains standard for the engines of larger cars, but air cooling for smaller vehicles is used and a new system of air cooling has made its appearance. As regards air-cooled engines, it has been found that the cylinders become rapidly carbonized with burned oil. Also an excess of oil in the combustion chamber is a prolific source of spark-plug troubles.

In one car this year there is used an engine which is oil-cooled, the method being to increase to about double the quantity of oil carried and to give it a free circulation over the outside of the cylinder walls, the outside of the valve seats, the valve stems and springs, the inside walls of the cylinders and the interior surfaces of the pistons. Preliminary tests have been satisfactory.

Cast iron appears still to be the favorite material for pistons. Of late there has been a tendency to decrease the thickness of piston rings and it is becoming common to use for narrow rings fitted to each piston, three compression rings at the top and a scraper ring at the bottom of the skirt.

As regards valves, the use of multiple valves has not made much progress in touring-car engines. Overhead valves are, however, steadily gaining in popularity, especially on engines of small cubical capacity.

Skew gears and spiral bevel gears are used, but the production of a gearing sufficiently quiet and inexpensive is a matter which taxes the ingenuity of engineers. The regular practice is to use an overhead valve gear operated by push rods from a camshaft containing in the crankcase, which is easier to manufacture commercially.

In regard to lubrication and carburation, the situation in England appears to be essentially the same as in America.

The outstanding feature in brake design is the introduction of front-wheel and four-wheel systems. It is only questions of expense that retard the adoption of front-wheel brakes for the less expensive cars, but much experimenting is in progress. In most cars where the open propeller shaft is used, the transmission brake is employed; also opinion is veering round to the idea that a compensating device is not necessary for rear-wheel brakes, but that some form of linkage which allows a slight spring is effective and less liable to get out of order.

Disk wheels are making steady progress, owing to the fact that they can be produced cheaply and are very easy to keep clean. Most of the small cars are now fitted with disk wheels, the sole objection being their liability to exaggerate any noise emitted by the back axle. (*The Autocar*, vol. 47, no. 1360, Nov. 12, 1921, pp. 945–953, illustrated, *g*)

PIPE (See Mechanics)

POWER-PLANT ENGINEERING (See also Air Machinery)

Preheating Air to Furnace by Flue Gases, E. R. Welles, Mem. Am.Soc.M.E., and C. T. Mitchell. The problem as to whether air delivered to furnaces can or cannot be preheated by flue gases is more an economic than a mechanical one, the chief concern being to find how large an apparatus can be built and still obtain a reasonable return on the investment.

Economy from preheating air would manifest itself in reducing coal consumption per unit of power output, as such coal would be needed to preheat the air in the furnace. In other words, the beginning of the heat cycle would be moved up a notch.

In regard to the furnace control with hot air, there is the choice of two courses. The quantity of air can be reduced in proportion to the reduction of coal, thus raising the furnace temperatures and probably lowering the stack temperatures. All conditions can be maintained as they were with cold air, using enough warm air to keep the furnace temperatures, and hence also the stack temperatures, unchanged.

From such evidence as the authors have we should expect no trouble regarding furnace control, but a greater tendency to burn out the grates and tuyeres, increasing with the temperature of the air.

Preheating would be particularly helpful with powdered coal and would immediately widen its field of application.

In order to determine the economical size of a preheater, the writers attempt to develop an expression for the efficiency of such a unit for varying capacity of heating surface. To do this they assume that the heat-transfer apparatus consists of a sheet-metal condenser filled with steel tubes. The flue gas travels through the tubes and the cold air around the tubes, or vice versa, the flow being countercurrent in order to keep the temperature difference nearly constant. The weight of the flue gas per hour is taken the same as the weight of air and the velocity of the two and specific heat are the same, the latter being 0.25. The final formula for the efficiency of the heater under these assumptions is—

$$\frac{1}{\frac{W}{2AK}+1}$$

where W = lb. of air per hr.; A = heating surface of the preheater in sq. ft.; and K = heat-transfer rate in B.t.u. per sq. ft. per hr. per degree temperature difference between the surface of the tube and the adjacent air. (This quantity must also take care of any mechanical or structural limitations in the heater.) The proper value for K here is of determining influence and yet it is still quite uncertain, and all things considered the writers expect the value of K in a properly designed heating unit to be not less than 4 and possibly as high as 10. From this point of view the diagrams in Fig. 12 become of interest. Each curve has a point of greatest curvature and it is to be anticipated by the correct size of the heater for any given set of conditions will lie approximately under that point. If we know the cost of heaters per square foot and also the true value of K, it becomes a simple matter to determine the size of heater giving the greatest net return on the investment.

A numerical example is given in the original article. The entire matter seems to be yet in the initial stages of development, and as an editorial in the same issue of *Power* (p. 84) points out, the commercial success of an air preheater is still uncertain. (*Power*, vol. 54, no. 22, Nov. 29, 1921, pp. 844–846, 1 fig., *dg*)

The Design of an Internally Fired Superheater, Prof. W. R. Woolrich, Mem.Am.Soc.M.E. Some dats of work done along these lines at the University of Tennessee. Experiments were tried as early as 1910 at the University of Tennessee to superheat steam by the combustion of gas, the burner operating within the steam main against the steam-main pressure. In 1916–17 a design was assembled by the author. Fundamentally, the apparatus consisted of a commercial air-atomizing oil burner designed for high pressures with its tip projecting into the steam pipe. In actual tests with a burner ignited and the steam line closed, it was found that no adjustment would give a suitable flame at the burner tip and as soon as the outside supply of air was shut off the flame would go out. This was because the commercial oil burner is designed to secure only a part of its air supply from the inside, replying on the surrounding air to make up the deficiency.

In 1919 H. E. Ayres took up the problem as an undergraduate thesis. In this case a new burner was made up representing a combination of two standard oxy-acetylene welding torches with several added features.

This work was continued by O. A. Kraehenbuehk, but the results at first were very unsatisfactory. No difficulty was experienced operating the burner in the closed main without steam, but when the steam was turned on at any working pressure the flame would be extinguished.

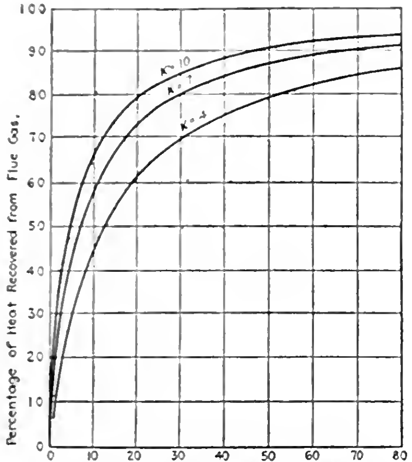

Fig. 12 Curves Showing Relation Between Size of Air Preheater and Recovery of Heat in Flue Gas (*K*-Heat-Transfer Rate)

After a series of adjustments operation was secured but of a very erratic character, the burner at times working steadily for periods as long as an hour. On the whole it has been proved that gas can be burned in the presence of high-pressure steam, but the influence of non-condensable by-products supplied to the steam by these means on condensation has not been determined.

The method may be applicable, however, to superheating of exhaust steam to be used in dye tubs, laundries, and, generally, processes where steam temperatures over 212 deg. fahr. are required. (*Power*, vol. 54, no. 19, Nov. 8, 1921, pp. 717–718, 2 figs., *d*)

Waste-Steam Turbine at Coal Mine

Mixed-Pressure Turbine Installation with a Regenerator at a Coal Mine, C. W. Smith. Description of the power plant recently installed at the Nokomis Mine in Illinois.

Prior to the installation of the plant all electric power used was purchased from outside, while the hoist, fan engine and several pumps were supplied by steam from six horizontal return-tubular boilers. This system resulted in very high operating costs for power, especially during periods of slack work. The costs have increased still more in the last two years when the power companies' rates were almost doubled. Another objection to this system of operation was the numerous and expensive shutdowns caused by frequent failures of the utility plant to deliver current.

Because of this it was decided to install a power plant sufficient to take care of all requirements. In order to conserve steam it was decided to electrify all machinery on the surface with the exception of three car-puller engines. This not only decreased steam consumption generally but reduced condensation in the various steam lines.

In order to utilize the waste steam from the hoist engine a mixed-pressure turbine was selected for the main unit of 1000 kw. capacity, in addition to which a 300-kw. high-pressure turbine was installed to handle the night load.

The system is as follows: The exhaust steam as it comes from the hoist engine passes through an 18-in. header to the Rateau regenerator. This is 9 ft. in diameter and 25 ft. long and is equipped with back-pressure valves set at 3 lb., which is the maximum back pressure on the hoist engine. From the regenerator the exhaust steam passes through an oil separator to the low-pressure side of the turbine. When the pressure in the regenerator falls to about 1.5 lb. per sq. in. below the atmospheric pressure, the governor on the mixed-pressure turbine automatically admits enough live steam to carry the load until the pressure in the regenerator is again sufficient to carry the load alone. The 300-kw. high-pressure turbine is equipped with a jet condenser. The circulating water from this condenser is not passed through the spray nozzles handling the cooling water on the main condenser, as this would require an additional circulating pump. This cooling water is allowed to circulate from the discharge near one end of the pond to the suction line on the opposite end. During the normal operation for which this unit was intended this arrangement is entirely satisfactory. Even in the summer months the temperature of the pond rises only a few degrees. When this unit has to be operated for more than 16 hr. a day, as sometimes happens when the mine is not working, the circulating pump on the large condenser is operated once or twice a day for a period of approximately an hour in order to cool down the temperature of the pond. This has proved a highly satisfactory manner of eliminating an additional circulating pump and of saving the power required for its operation.

It is stated that no trouble has been encountered as regards the performance of the mixed-pressure turbine in shifting from high-pressure to low-pressure steam under variable loads. It has also been found that the regenerator instead of increasing the back pressure on the hoisting engine has caused it to be reduced. However, the original exhaust lines were too small. Under conditions existing at the Nokomis Mine only two men have had to be added to the power-plant force since this plant was put into operation.

The installation is of considerable interest to deep-shaft mine engineers. The steam hoist has been considered rather wasteful to operate, and if this wastefulness can be overcome by the installation of a mixed-pressure power plant, this would tend to increase materially the field of usefulness of this latter. (*Coal Age*, vol. 20, no. 19, Nov. 10, 1921, pp. 753–757, 7 figs., *d*)

PUMPS

Centrifugal Pumps in Sugar Refineries

Centrifugal Pumps in Sugar Refinery, Claude C. Brown, Mem.Am.Soc.M.E. For various reasons motor-driven centrifugal pumps are rapidly growing in favor in sugar-refining work, but the type of pump used has some special features developed to meet sugar needs and conditions.

In Western sugar-refining plants where great quantities of salt water are used for condensing purposes in connection with the boiling of sugar in vacuum pans, the pumps are situated on the ground floor of the plant where they have a suction lift from the bay of from 12 to 15 ft. according to the tide and a lift of approximately 150 ft. to the pan condensers. When first installed trouble developed. Thus, it was difficult to hold the suction at low tide, as air was finding its way into the pump suction. The introduction of this air was eliminated by tightening all leaks in the suction line, smoothing it out and eliminating air pockets and sharp turns. Furthermore, it was found that at the points in the casing casting adjacent to the runner hub there were shoulders which still continued to act as air pockets. These shoulders were vented to the outer casing with a 1/4-in. line which effectually destroyed any detrimental effect they might have had.

The method of priming these pumps is of interest. A small vacuum pump was installed near the battery of pumps and a $^1/_2$-in. line run to each pump. When it is desired to start one of the centrifugal pumps, the small vacuum pump is started first and any number of salt-water pumps can be primed immediately.

As first installed the salt-water pumps consisted of cast-iron casings with bronze and cast-iron runners and shafts made of Cumberland steel. Before very long powerful corrosion set in, affecting both casing and runner. The cast-iron casing was then replaced by a bronze casing, and the Cumberland steel shafts by shafts of 3 per cent rolled nickel steel. Further, bronze sleeves were shrunk on over the portions of the shaft that were inside the pump, after which all trouble from corrosion disappeared.

For the pumping of liquors, syrups, etc., other questions of corrosion and erosion came up. Here again the most successful results were obtained with combinations of bronze casing, bronze runner, and steel shaft with bronze bushing. This withstood corrosion but not erosion, and where this latter was especially noticeable, cast-iron casing, chrome-vanadium steel runner and monel-metal shaft were used which gave good satisfaction.

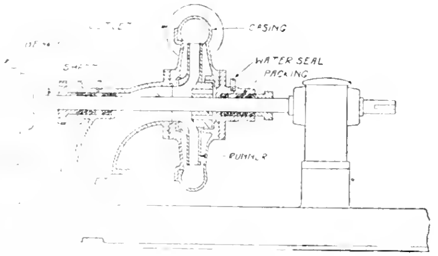

Fig. 13 Centrifugal Pump with Water-Sealed Packing for Pumping Sugar Solution

In the pumping of sugar solution it is absolutely necessary that this latter shall not come in contact with the pump packing. Because of this water-sealed packing (Fig. 13) is used. A $^1/_4$-in. line of fresh water is connected within each packing gland and just enough water allowed to enter the gland to seal it and prevent the sugar from coming out.

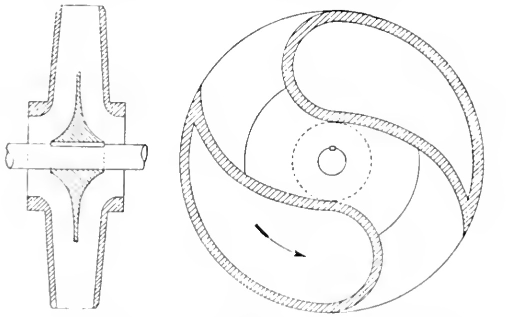

Fig. 14 Sewage-Type Runner with Double Suction

As regards the question of type of pump runner, it has been found in sugar plants that the most successful type for general all-round requirements is the sewage-type runner (Fig. 14). The open-type runner, which resembles an open star, has also proved successful, particularly for pumping liquids which have matter in suspension. (*Power Plant Engineering*, vol. 25, no. 22, Nov. 15, 1921, pp. 1087–1088, 4 figs., *d*)

SPECIAL MACHINERY

Bar Mills Adapted to Handle Alloy Steel, J. D. Knox. Description of a new unit built by the Central Steel Company, Massillon, Ohio, the characteristic feature of which is that care has been taken to adapt the mill to peculiarities of alloy steel. Only some of the features can be noted here. Thus, the motors driving the 16- and 12-in. roll trains are cooled by air washed in a Carrier-type washer.

The 18-in. finishing mill is driven by a 2200-hp. variable-speed motor designed to operate from 303 to 505 r.p.m. The gear set with a ratio of 115 to 34 provides various roll speeds ranging from 90 to 150 r.p.m. (*Iron Trade Review*, vol. 69, no. 20, Nov. 17, 1921, pp. 1275–1281, 11 figs., *d*)

SPECIAL PROCESSES

Bending Lock-Seam Tubing. Lock-seam tubing is made with the folded seam. Such tubing can be used for automotive exhaust manifolds providing it can be bent to the forms required for this purpose without opening the seams. The method of making the bends by first filling the tubing with molded lead or rosin was found, however, to be too expensive for commercial production.

In order to meet this problem a special form was made for use on a No. 5 pipe-bending machine by the Wallace Supply Manufacturing Co. of Chicago, Ill. This equipment is so designed that the work is continually supported around the complete circle both inside and outside at the point of bending. The form around which the work is bent is grooved to embrace half the circumference of the pipe and a similar grooved follower embraces the other half of the pipe. There is a mandrel of the same size as the inside diameter of the work to be bent. As the pipe is bent around the form both the follower and mandrel move with it, so that they always support the work at the point of bending and the metal is made to flow. (*Machinery*, vol. 28, no. 4, December 1921, pp. 289, *d*)

STEAM ENGINEERING (See also Engineering Materials)

Investigation of Breakdown of 30,000-Kw. Turbine. Data of an investigation by Prof. H. F. Moore, Mem.Am.Soc.M.E., and Geo. L. Kelley of the accident to the 30,000-kw. turbine of the Philadelphia Electric Co. which occurred on Saturday morning, Sept. 3, 1921.

The machine was being tested for overspeed and was gradually brought to 9 per cent above its normal speed of 1500 r.p.m.; the throttle was then closed by the governor, and the machine began to slow down. A few seconds after the main throttle had closed a loud hissing noise was heard, instantly followed by two heavy crashes and a shower of broken pieces of metal.

The investigation has shown that the low-pressure casing was cracked, the steam passages from the high- to the low-pressure stages were broken, all the shaft bearings were broken and the 20-in. mainshaft likewise.

The following explanation is offered by Professor Moore: Under running conditions the passage from the high-pressure to low-pressure stages is under a bursting pressure considerably greater in magnitude than the collapsing pressure existing when there is a vacuum in the passage, and moreover the casting is designed with stiffening ribs on the outside, so that under bursting pressure the bulging of the passage will tend to cause the ribs to be in tension in their outer fibers and the plates to be in compression. Under vacuum this state of affairs would be reversed. He believes, therefore, that it would seem unlikely that the steam-passage casting would fail when the interior was under vacuum and the fractures are explained as secondary failures.

One of the most striking features of the wreck was the breaking of the mainshaft and the tearing up of the surface of the exciter armature. The character of the metal at the break would lead one to believe that there was dragging of one piece of metal over the other as fracture occurred.

As regards the primary cause of failure, a theory was offered to the effect that a polepiece of the exciter field became loose and was jammed into the armature, causing enough twisting or bending to break off the exciter frame and the main shaft, throwing the remainder of the shaft sufficiently out of line to cause the wreck of the turbine disk and bearing. The state of the armature would appear to support this theory.

From all evidence it would appear that the failure of the main shaft was one of the last events in the wreck.

The fractures in the turbine disk show evidence of a progressive crack ascribed to the existence of lateral vibrations in the disk. This again is explained as follows: The steam jet enters on one side of the buckets and leaves from the opposite side, any frictional lateral drag from the steam being all the time in one direction. As the disk revolves the steam must strike on any given blade with a regular rhythmical variation of force. At certain speeds this rhythmical variation might be so nearly in tune with the natural period of lateral vibration for the disk that severe repeated bending stresses would be set up. Moreover, these lateral vibrations may have been numerous enough to develop such a typical progressive fracture as was found in this case.

In addition, it was found that the turbine disk had only a rough surface finish and carried deep tool marks which might have served to localize the effects due to sidewise vibration. In fact, recent tests at the University of Illinois made in the course of the joint investigation on fatigue of metals have shown that such surface conditions might reduce the ability of the disk to resist lateral vibrations by as much as 20 per cent.

If the primary cause of the wreck were a progressive failure of the disk, it is easy to show that the wreck might be expected to occur at a time when for any reason the speed is particularly high. In this instance, for test purposes the speed was increased to 109 per cent of its normal magnitude which resulted in an increase of centrifugal force to 1.19 times its normal value, which is a very material increase indeed. (*Power*, vol. 54, no. 21, Nov. 22, 1921, pp. 788–793, 13 figs., *dg*)

STEAM TURBINES (See Mechanics)

SUGAR REFINERY (See Pumps)

TESTING AND MEASUREMENTS

Measurement of Air Velocities and the Testing of Anemometers, Jas. Cooper. The two best-known methods of measuring air velocity in mines, namely, by the anemometer and by means of smoke, are both liable to serious error. In particular, as regards anemometers, the friction of the parts has the effect of making anemometer readings correct for only one particular velocity. At other velocities accuracy can be achieved only by corrections for the influence of friction, and at low velocities the corrections may be greater than the speed registered by the instrument.

In view of this, means for testing anemometers have been provided at the Heriot Watt College in Edinburgh. There is already in England an installation for testing anemometers at the National Physical Laboratory, but they are not tested there at velocities lower than 600 ft. per min., while air speeds under that figure are common in mines and the need for calibration is particularly imperative for velocities below 300 ft. per min. The testing table used for calibrating anemometers is described and it is stated that figures obtained from the tests have been compared, first, by observation of smoke velocities, and second, by walking tests with the meters over a measured straight line in a still atmosphere.

The data of tests were charted and it was found that although the charts plotted from the tests were similar in form to those sent out by the makers of the instruments, the figures of correction varied widely. (Paper presented in October, 1921, before the Mining Institute of Scotland, abstracted through *The Iron and Coal Trades Review*, vol. 103, no. 2798, Oct. 14, 1921, p. 540, *ep*)

Friction of Cup-Leather Sleeves

Tests on Cap-Leather Sleeve Friction, Eugen Irlon. In the measurement of power in testing materials with machines operated by means of levers or weights or the like, precision to within 1 per cent is usually obtainable with comparative ease. On the other hand, when the power is applied by hydraulic means, its measurement is complicated by the fact that considerable friction is present at the cup-leather sleeve, depending on the fluid employed as a pressure medium and the material of the packing, and therefore subject to considerable variation. As a matter of fact, unless this friction is measured quite frequently, considerable errors in final results of measurement of power applied may be found. Data of such tests of friction in cup-leather sleeves are presented in this article. All the data in the abstract will be given in the original metric units and the conversion factors to American units appended in a note at the end of the abstract.

This is not the first attempt to measure such friction and an investigation on the same subject has been published by A. Martens in the *Zeitschrift des Vereines deutscher Ingenieure*, 1907, p. 1184.

The present tests were carried out in a 75-ton hydraulic bending machine water-driven by a three-piston electric pump. The pressure cylinder had a useful piston area $F = 380.13$ sq. cm. (58 sq. in.) The dial of the pressure gage was graduated in atmospheres and kilograms.

The division into kilograms was obtained experimentally by using the average friction value obtained by Martens and by adding this value to the pressure in kilograms as obtained from the equation—

$$P = Fp \quad \ldots\ldots\ldots\ldots\ldots\ldots\ldots \quad (1)$$

where P is the theoretical pressure, F the piston cross-section in square centimeters and p the pressure in the pressure cylinder in kilograms per square centimeter. This gave Equation (1) the form—

$$P_1 = (F\,p + F\,\frac{pR_p}{100}) = Fp\ \left(1 + \frac{R_p}{100}\right) \text{ in kg} \ldots\ldots (2)$$

where P_1 is the actual pressure in kilograms, and R_p the cup-leather sleeve friction in per cent as found by Martens.

The total friction was measured by a special gage having a maximum range of 100 (metric) tons (=110 short tons). Two other pressure gages were used with ranges of 100 tons and 200 tons, respectively, the errors of which were determined by careful calibration. Table 1 gives the friction values found by Martens in 1907 as percentages of the pressure in kilograms per square centimeter. The values in column 2 have been calibrated from Equation (1), and the values in columns 3 and 4 taken directly from the tests of Martens. By adding the values in columns 2 and 4 are obtained the values of column 5 giving a total effective pressure p_1 in the pressure cylinder in kilograms per square centimeter.

The tests have shown, as is evident from Table 2, that the differences between the actual experimental data as shown by the gage and the values in the curve of Martens (curve *A*, Fig. 15) in ordinary cases do not amount to more than 0.5 to 1.1 per cent, and that therefore the data of the two series of tests are in fairly good agreement.

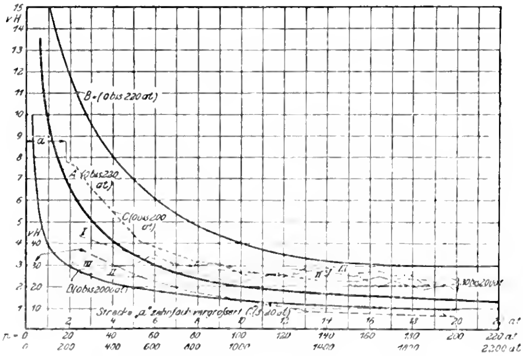

Fig. 15 Curves of Cup-Leather Friction

(Curve *A*, Martens; curve *B*, Puppe; curves I, II, III, author's tests on 300-ton concrete press; curve *C*, author's tests on 75-ton bending machine. (*Bis* = to; *at.* = atmospheres; *vH* = per cent; *Strecke "a" zehnfach vergroessert* = section "a" magnified ten times.))

On the other hand, however, in nearly all cases the sleeve-friction values as obtained by the present author were higher than those obtained in the Martens test, which may be due to the fact that the pressure fluid in the present instance was not entirely free from dust and fine grains of sand, which is also the usual condition in actual operation. It was also found that the first measurements carried on after a period of several hours of rest of the measurement always gave slightly higher friction values than later tests. This was particularly so in early morning tests which followed the idle period of 10 to 15 hr. when the leather cup had a chance to become dry. After the piston has moved up and down for some time the

values come back to within 0.5 to 1.1 per cent of the Martens values. The friction values obtained by Dr. Eng. Puppe in 1910 are given in curve *B* for the sake of comparison. Furthermore, the present author has carried out several comparative tests during the war on a 300-ton concrete press.' The data of these tests are given in curves I, II and III, Fig. 15. All these curves agree fairly well with each other, though the high frictional values of Dr. Puppe would indicate that at high pressures rubber packing rings produce a considerably higher friction than leather cups.

In Fig. 16 is graphically indicated the relation between the load *P* and the friction R_p. From the appearance of the curve of friction it would seem that at a pressure of 10 tons, or roughly 25 atmos., the pressure amounts to only 6.6 per cent, while at 75 tons, or, say, 200 atmos., it is only 2.1 per cent.

The division of the pressure-gage dial into kilograms appears to be a material improvement in testing machines. In the majority of cases one may allow an error of ± 2.5 per cent, although a greater precision can be obtained by the use of a control manometer.

Table 3 gives the cup-leather friction in percentages of *Fp* and *f p*, where *f* = 350 sq. cm. is the sum of all surfaces of the cup leathers in friction. The values in the last column are also of interest as they give the coefficients of friction of cast iron against leather at various pressures per unit of area. [Note: 1 sq. cm. = 0.1550 sq. in.; 1 kg. per sq. cm. = 14.223 lb. per sq. in.; 1 metric ton = 1000 kg. = 2200 lb.] (*Zeitschrift des Vereines deutscher Ingenieure*, vol. 65, no. 39, Sept. 21, 1921, pp. 1016–1017, 2 figs., *eA*)

VARIA

Agitation for Changes in Canadian Patent Law. John Munnock, Division Court Clerk of the Sault Ste. Marie District, in speaking before the Board of Trade of that town, advocated important changes in the practice of the Canadian Patent Act.

Under the law Americans obtaining patents in Canada are required to begin manufacture in Canada within two years, but may obtain an extension for one more year. It is claimed that this provision of the Act is not enforced and that there are 10,000 articles that could have been manufactured in Canada but are instead imported from America.

It is also claimed that even if an American patentee failed to meet the requirements of the Act as regards manufacture in Canada, he can still obtain an injunction against a Canadian manufacturer infringing his patent.

To meet this situation, the speaker proposes a closer check on the compliance of foreign patentees with the requirements of Canadian laws, and it is claimed that he has carried the matter to Premier Meighen, who is said to have expressed regret that action could not have been taken by the government prior to election.

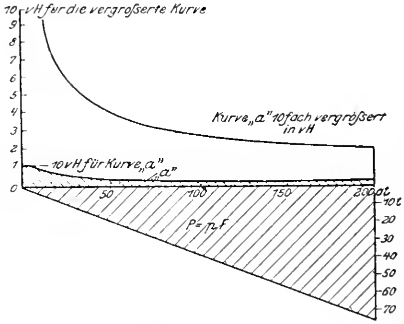

Fig. 16 Relation Between Load *P* and Friction *Rp* for Loads from Zero to 200 Atmos.

(*vH für die vergroesserte Kurve* = per cent for the magnified curve; *Kurve "a" 10fach vergroessert in vH* = curve "a" magnified ten times in per cent.)

The subject was expected to come up for discussion at the Brantford Convention of the Canadian Associated Boards of Trade in November, 1921. This matter affects a large number of American products, among others being American typewriters, cash registers, adding machines, check protectors and machine tools. (*Canadian Machinery and Manufacturing News*, vol. 26, no. 21, Nov. 24, 1921, p. 52, *g*)

CLASSIFICATION OF ARTICLES

Articles appearing in the Survey are classified as *c* comparative; *d* descriptive; *e* experimental; *g* general; *h* historical; *m* mathematical; *p* practical; *s* statistical; *t* theoretical. Articles of especial merit are rated *A* by the reviewer. Opinions expressed are those of the reviewer, not of the Society.

Starting Aero Engines at low Temperatures. (Air Board, Ottawa, Canada, Technical Memo No. 15.) From preliminary reports of Experiments carried out last winter by Professor Robb, at Edmonton, it is suggested that the following means of starting Liberty engines at low temperatures may be found to be effective. A complete report will be circulated as soon as received. It is suggested that for the efficient doping of the engines some form of priming pump similar to the Rolls-Royce primer is necessary. At temperatures over 20 deg. fahr., liberal doping with gasoline is sufficient except that the motor will require to be turned over several times after doping to ease it up. At temperatures between 20 deg. fahr. and ten deg. fahr. doping with a mixture of three parts gasoline to one part of ether will be found to be effective. At temperatures around zero, a one to one mixture is satisfactory. At temperatures in the neighborhood of 12 deg. below zero, it will be found that a mixture of two parts ether to one part gasoline is required.

ENGINEERING RESEARCH

A Department Conducted by the Research Committee of the A.S.M.E.

Research Résumé of the Month

A —RESEARCH RESULTS

The purpose of this section of Engineering Research is to give the origin of research information which has been completed, to give a resume of research results with formulas or curves where such may be readily given, and to report results of non-extensive researches which in the opinion of the investigators do not warrant a paper.

Apparatus and Instruments A1-22. SCALES. Technologic Paper 199 of the Bureau of Standards outlines scientific and systematic procedure for accurate testing of large-capacity compound lever scales by a method developed by the Bureau. Apparatus is described and method of testing is explained. Paper may be obtained at a cost of 5 cents from the Superintendent of Documents, Washington, D. C.

Cement and Other Building Materials A1-22. BRICKS. Sand-Lime and Other Concrete Bricks is the subject of Special Report No. 1 of the Building Research Board of Great Britain. The report is divided into two sections, one on sand-lime bricks, the other on cement-concrete bricks. Each section treats of materials, costs, quality, uses and manufacture. It may be obtained at 4d from Imperial House, Kingsway, London, W. C. 2.

Friction and Allied Subjects A1-22. BALL AND ROLLER BEARINGS. Technologic Paper 201 of the Bureau of Standards describes the tests and gives the conclusions of tests performed on ball bearings and flexible roller bearings under various loads with balls and rollers of different sizes and different hardness with varying radii of races. This report is of great value to any one interested in design of ball and roller bearings. This may be obtained at 10 cents per copy from the Superintendent of Documents, Washington, D. C.

Fuels, Gas, Tar and Coke A1-22. THE COKING OF UTAH COALS. The Coking of Utah Coals is the subject of Report 2278 by Prof. S. W. Parr and T. E. Layng to the Bureau of Mines. Approximate and ultimate analyses were made. The oxygen content was very high. The oxygen-hydrogen ratio was also very high. This indicates a non-coking property. The preliminary tests seem to indicate this but this feature was overcome and a good quality of coke obtained accompanied by a series of by-products of more than usual interest and value. The ammonium sulphate produced was exceedingly constant and averaged 20 lb. per ton. Large-scale operations would probably increase this. The gas yield was low, being 3½ cu. ft. per lb. of coal. The production of gas was very uniform. The heating value of the gas was large. The tar yield averaged 25 to 30 gal. per ton. The coke yield amounted to approximately 60 per cent of the coal employed. It was dense, of good texture and adapted to the usual screen and sizing process. It would probably be suitable for metallurgical purposes. There is considerable volatile matter present in the coke varying from 8 to 12 per cent. The temperature used to carbonize the Utah coals did not exceed 750 or 800 deg. cent. Bureau of Mines, Washington, D. C. Address H. Foster Bain, Director.

Fuels, Gas, Tar and Coke A2-22. NATURAL GAS-GASOLINE BLENDS. Report 2279 of the Bureau of Mines on Natural Gas-Gasoline Blends, by D. B. Dow, was issued last September. Natural gas-gasoline is obtained by compression and collecting of natural gas. The gasoline dissolves a certain amount of volatile material which evaporates rapidly at atmospheric temperature and pressure. With lean natural gas the gas vapors are absorbed by absorbing oil, after which it is distilled from the saturated oil. This gasoline is of higher gravity and lower vapor pressure than the compression gasoline. To transport the volatile gasoline it must be blended with suitable material such as naphtha or weathered, in which case the volatile portion is allowed to evaporate causing loss. It is difficult to produce blended gasoline which is equal to refinery gasoline. Hence only a small amount of gas-gasoline can be blended with naphtha. Blends are sometimes made with kerosene and subsequently distilled, the kerosene acting as a carrying agent. Most common material is of naphtha range from 50 to 52 Baumé. Bureau of Mines, Washington, D. C. Address H. Foster Bain, Director.

Fuels, Gas, Tar and Coke A3-22. RECOVERY OF UNBURNED FUEL FROM BOILER FURNACE REFUSE. Report 2281 of the Bureau of Mines on the Recovery of Unburned Fuel from Boiler Furnace Refuse, by Thomas Fraser and H. F. Yancy, has just been issued. The report shows that washing may be used to recover a large portion of the unburned fuel. The results of the test showed that with $^3/_8$-in. screening and $^1/_8$-in. oversize 20 per cent of the refuse was regained as washed fuel. A one-table plant will handle five tons of boiler refuse per hour, producing one ton of fuel. The equipment for such a plant would consist of a roll crusher, a storage hopper, a screw conveyor, washing table and two inclined dewatering drag conveyors. If water is scarce or costly, overflow from sumps may be clarified and returned to the system. The operation would require the part time of one man. Bureau of Mines, Washington, D. C. Address H. Foster Bain, Director.

Heat A1-22. HEAT-TRANSFER COEFFICIENT. The heat transfer between hot and cold oil in double-pipe heat interchanger used in distilling gasoline shows an average value of 20.05 B.t.u. per hour per degree per sq. ft. In most cases the mean temperature difference computed by the log formula was about 70. The efficiency of heat transfer in apparatus averaged 78 per cent on account of radiation. Information is from reliable source but name is withheld.

Petroleum, Asphalt and Wood Products A1-22. VISCOSITY OF PETROLEUM OILS. The following notes are obtained from the thesis of Mr. Achille R. Albouze on the Logarithmic Relation between Temperature and Pressure of Petroleum Oils:

The logarithms of temperature and absolute viscosities of the oils were plotted and there was found to be a close adherence to a straight-line law from ordinary room temperature of 70 deg. fahr. to temperatures of 180 to 220 deg. fahr., depending upon the nature of the oils. Around this region of temperatures (180 to 220 deg.) there appears to be a "break" in the straight-line law, but after passing this critical point the oils then invariably follow another straight-line law up to 300 deg. fahr., but at a lesser rate of change of viscosity than at the lower temperatures. In other words, the absolute viscosities of the oils may be represented as two intersecting straight lines as far as 300 deg. fahr.

This critical point where the lines seem to break off is fairly uniform, as was evidenced on plotting gravities, absolute viscosities at 100 deg. fahr. and temperatures at which the breaks in the straight lines occurred. A study of these curves shows:

1 That the greater the density and absolute viscosity of an oil, the higher is the temperature at which the break occurs.

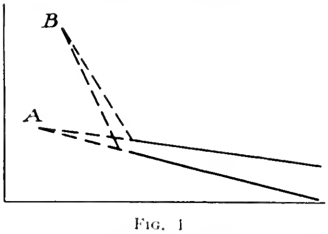

FIG. 1

2 The lines showing relations between viscosity and the "critical breaking temperatures" parallel themselves to a degree of remarkable closeness.

3 Oils of specific gravity below 0.9 show higher "breaking point temperatures" than oils of specific gravity greater than 0.9.

The oils purchased as "paraffin base" oils showed specific gravities at 60 deg. fahr. or less than 0.91 and their rate of change or loss of viscosity per degree of temperature rise was less than the so-called "asphalt and napthene" base oils. Comparing the "paraffin" base with the "napthene" base oils of similar absolute viscosity, it appears that the breaking-point temperature of the "paraffin" oils is generally from 15–20 deg. fahr. higher than the "napthene" base oils. The following table based upon the experimental data obtained in this laboratory (Mechanical Engineering Laboratory, Stanford University) serves to show these points more clearly.

Base of Oil	Sp. Gr. at 60 deg. fahr.	Abs. Visc. at 100 deg. fahr. (poises)	Temperature, deg. fahr., at which lower straight lines break
Napthene	0.92–0.94	0.25–0.75	180–195
Napthene	0.93–0.95	0.75–1.25	190–205
Napthene	0.94–0.95	1.25–2	205–215
Napthene	0.94–0.95	2–4	210–215
Paraffin	0.875–0.90	0.25–0.75	200–220
Paraffin	0.875–0.90	0.75–1.50	210–230
Paraffin	0.875–0.90	1.50–2.25	220–250

An examination of the lines on the logarithmic sheets indicate that the oils tend to converge toward a common point, this being particularly true of oils (or products of oils similarly treated) from the same fields. None of the oils tested showed a continuous straight line from room temperature to 300 deg. fahr., but all can be represented by two straight lines intersecting one another around the region of 200 deg. fahr., as shown in Fig. 1.

If the lines for the lower range of temperatures are prolonged it will be found that they tend to meet at a common point *A* of the diagram. In a similar manner the upper lines through viscosity determinations

from 200 to 300 deg. fahr. indicate a convergency also, but the point of intersection *B* appears to lie at a still further distance away from the point of convergency for the lower temperatures.

No further statements regarding the common points of intersection can be given here, other than to briefly indicate that there are evidences of there being such points, principally because a lack of time has made it impossible to study this particular case thoroughly.

The establishment of the existence of a common point of convergence would be of great practical importance. By this means it would be possible to know the absolute viscosity of any mineral lubricating oil (at any temperature) after one or two viscosity measurements had been made. If the absolute viscosity followed but one straight line over the entire range of temperatures instead of two, it would only be necessary to know the viscosity of an oil at any one temperature—the absolute viscosity of the oil being given by the line connecting the common point of convergence and the viscosity as found by measurement.

Viscosity and density measurements made at lower temperatures after the runs at 300 deg. fahr. had been obtained indicate that the oil underwent no appreciable changes. Most samples showed only a slight increase in viscosity and density due to evaporation. Experiments seemed to show that there were no measurable differences in viscosities regardless whether the values were obtained with increasing or decreasing temperature.

The two Mexican crude oils show also a characteristic straight line law from 150 to 300 deg. fahr. with only a slight tendency to indicate that they are made up of two broken lines. On cooling both samples showed increased viscosities due to the loss of low boiling point components.

Mr. Albouze's thesis includes in addition to the data and results of his own tests, a summary of which is given above, a study of all of the published data on viscosity of oils from various authorities and determined with various types of viscosimeters; a bibliography of physical and chemical tests for internal engine lubricating oils and a section devoted to notes and critical review of bibliography. The bibliography covers 188 publications. Address Prof. W. R. Eckart, Leland Stanford University, Stanford, Cal.

Rubber and Allied Substances A1-22. Tests of Rubber Goods. Circular 38 of the Bureau of Standards has just been issued. The subject of the circular is the test of rubber goods giving the physical and chemical methods used at the Bureau with an introductory portion giving information concerning crude rubber and manufacture of rubber goods. Materials used in compounding rubber are classified and process of manufacture described, with brief summary of the detail of manufacture of tires, tubes, mechanical goods, druggists' sundries, methods of physical tests with data of results as well as methods of chemical analysis are given. Methods of testing fabrics are included. The Appendix contains a list of governmental specifications, a bibliography of papers published by the Bureau and of the more important books and periodicals that deal with rubber. A table of specific gravities of the common compounding ingredients is given. Circular may be obtained from the Superintendent of Documents, Government Printing Office, Washington, D. C. for 20 cents.

Safety Devices A1-22. Head and Eye Safety Code. A second edition of the Head and Eye Safety Code is soon to be published by the Bureau of Standards. This will include specifications for goggles, welding helmets and other protectors. Bureau of Standards, Washington, D. C. Address S. W. Stratton, Director.

Steam Power A3-21. Steam Action in Simple Nozzle Forms is the subject of a paper read by A. L. Mellanby and William Kerr before the British Association in August, 1921. A paper on Pressure Flow Experiments on Steam Nozzles was read before the Institute of Engineers and Shipbuilders in Scotland November, 1920, while in February, 1921, a paper on the Losses in Convergent Nozzles was published. This paper was read before the Northeast Coast Institute of Engineers and Shipbuilders. The various papers give pictures of apparatus used, curves showing observed data and theoretical curves discussing the action of steam jets in nozzles. These sets of papers contribute largely to our present knowledge of steam flow.

B—Research in Progress

The purpose of this section of Engineering Research is to bring together those who are working on the same problem for cooperation or conference, to prevent unnecessary duplication of work and to inform the profession of the investigators who are engaged upon research problems. The addresses of these investigators are given for the purpose of correspondence.

Apparatus and Instruments B1-22. Acidity and Alkalinity Recorder. An instrument for determining the alkalinity or acidity of boiler feed to automatically control additions of caustic soda to eliminate acid conditions. The principle used is that of measurement of concentration of the hydrogen ions. A hydrogen electrode and calomel electrode are immersed in a by-passed flow of feedwater from the heater tanks. The potential difference measured depends on the H-ion concentration. Results of data so far indicate that method would prove satisfactory. Address E. A. Keeler, Leeds & Northrup, Philadelphia, Pa.

Automotive Vehicles and Equipment B1-22. Experimental Tunnel for Studying Exhaust Gas. See *Internal-Combustion Motors B11-21*.

Boilers and Accessories B1-22. Acidity and Alkalinity Recorder. See *Apparatus and Instruments B1-21.*

Internal-Combustion Motors B1-22. Experimental Tunnel for Studying Exhaust Gas. Report 2288 of the Bureau of Mines on the Bureau of Mines Experimental Tunnel for Studying the Removal of Exhaust Gas, by A. C. Fieldner and J. W. Paul, gives an account of the purposes of the investigation and results found as reported under *Automotive Vehicles and Equipment A5-21*, in Mechanical Engineering for June, 1921. The report gives the following particulars of the construction of this experimental tunnel.

An oval track having an axial length of 400 ft. and having similar construction to that of the ducts proposed in the Hudson River Tunnel, was constructed under ground with a cross-section approximately 9 ft. wide and 8 ft. high. Above the tunnel is an air duct 3 ft. high and below the floor another air duct 3½ ft. high. Either duct may be used for introducing fresh air or for exhausting contaminated air. The tunnel accomodates the smaller types of five-passenger cars. It is completely equipped with sensitive apparatus for measuring temperature, humidity, air pressure and air velocity. Forty-eight air-sampling tubes are installed at eight cross-sections of the tunnel to obtain samples for chemical analysis and to determine diffusion and concentration of exhaust gases. The experimental tunnel tests will include physiological and psychological observations of the effects on the man driving the cars, of temperature, humidity, rate of air flow, smoke and exhaust gases. Ten cars at 40-ft. intervals will be run at the rate of 10 miles per hour and 21,000 cu. ft. of air per minute will be introduced so as to keep the carbon monoxide at 4 parts per 10,000 parts of air. Each driver and observer will be subjected to examination before and after the tests. The tunnel is situated 130 ft. below the surface of the ground and 150 ft. from the pit mouth. The study will include the diffusion of exhaust gases by transverse ventilation, bottom to top and top to bottom, temperature and smoke conditions as effected by operation of motor cars, physiological and psychological effects of temperature, exhaust gases and smoke, final check of previous investigation and practical demonstration of solution of problem.

Bureau of Mines, Washington, D. C. Address H. Foster Bain, Director.

Metallurgy and Metallography B1-22. Deoxidizers. Progress Report to the Division of Engineering of the National Research Council on Substitute Deoxidizers gives some of the work which has been done by the Committee on this subject. The Committee has standardized its work and is now treating standard metal with various deoxidizers in an atmosphere of nitrogen within an induction furnace. The standard metal is commercially pure American ingot iron and iron oxides melted together in an electric furnace in such proportions that the iron thus made give 0.5 to 0.6 per cent oxygen. When this standard metal is melted the deoxidizer is added and allowed to act for 5 or 10 minutes with the heat on the furnace. The melt is then allowed to solidify or is poured into a chill mold. The ingot is then split, examined and photographed. One-half is then forged and the forging properties noted. The forged ingot is then examined microscopically for inclusions and chemically for oxygen and residual amounts of deoxidizing elements.

This work has been repeated in some cases in a 40-lb. experimental electric furnace of the American Rolling Mills Company. Each deoxidizer is to be added in different amounts to determine the proper amount to be used. Certain of the deoxidizers have proven of special value in preventing segregation. Others indicate inability to replace manganese in eliminating sulphur red shortness. Some have shown a refining influence on grain structure and others have shown the possibility of reducing ingot loss from discards due to shrinkage cavities. In the earlier work the Committee has found 73 combinations of elements which promise to be of value as deoxidizers. All contain manganese, but many of them contain less than 2 per cent of this element. As the first steps of deoxidation could be effected by these alloys and the final deoxidization with high-percentage ferromanganese, a great saving can be accomplished.

The functions of the deoxidizer are:

1 To produce the greatest possible yield of sound ingots free from blow holes and with a minimum amount of shrinkage cavities

2 To produce steel possessing satisfactory rolling and forging properties

3 To produce metal free from iron oxide, slag or other solid inclusion, and

4 To produce steel with maximum freedom from dissolved gases.

The report is made by Dr. J. R. Cain, Chairman, Committee on Substitute Deoxidizers. Address Division of Engineering, National Research Council, 29 West 39th St., New York City.

Properties of Engineering Materials B1-22. Corrosion of Pipes. The Bureau of Standards is beginning an investigation of the corrosive action of soil upon iron pipe. Investigations are being made with the coöperation of the Bureau of Soils, Pipe Manufacturers, Public Utility Companies and the Bureau of Standards. Forty locations have been selected representing different kinds of soil found through the United States, and in each locality a number of samples of each kind of iron and steel pipe in commercial use will be buried. One of these pipes will be uncovered from time to time to determine the rate of corrosion. Complete data of the physical and chemical properties of soil and pipes will be obtained. Extensive laboratory experiments will be conducted to determine the effects of variations and characteristics of both soil and pipe materials. Tests will also be made of representative pipe coverings. The investigation will probably take eight to ten years. The progress report will be published from time to time. Bureau of Standards, Washington, D. C. Address S. W. Stratton, Director.

Protective Devices B1-22. Corrosion of Pipes. See *Properties of Engineering Materials B4-21.*

Safety Devices B1-22. Safety Code for Logging Operations. A National Safety Code for Logging and Saw Mill Operations is being prepared by the Bureau of Standards with the assistance of a Sectional Committee. This Code is nearing completion. Bureau of Standards, Washington, D. C. Address S. W. Stratton, Director.

C—Research Problems

The purpose of this section of Engineering Research is to bring together persons who desire cooperation in research work or to bring together those who have problems and no equipment with those who are equipped to carry on research. It is hoped that those desiring cooperation or aid will state problems for publication in this section.

D—Research Equipment

The purpose of this section of Engineering Research is to give in concise form notes regarding the equipment of laboratories for mutual information and for the purpose of informing the profession of the equipment in various laboratories so that persons desiring special investigations may know where such work may be done.

E—Research Personnel

The purpose of this section of Engineering Research is to give notes of a personal nature regarding the personnel of various laboratories, methods of procedure for commercial work or notes regarding the conduct of various laboratories.

F—Bibliographies

The purpose of this section of Engineering Research is to inform the profession of bibliographies which have been prepared. In general this work is done at the expense of the Society. Extensive bibliographies require the approval of the Research Committee. All bibliographies are loaned for a period of one month only. Additional copies are available, however, for periods of two weeks to members of the A.S.M.E. These bibliographies are on file at the office of the Society.

Machine Tools F1-22. Torque and Power Required for Tapping and Threading. A bibliography of three items. Search No. 3469. Address A. M. Greene, Jr., Rensselaer Polytechnic Institute, Troy, N. Y.

WORK OF THE A.S.M.E. BOILER CODE COMMITTEE

The Boiler Code Committee meets monthly for the purpose of considering communications relative to the Boiler Code. Any one desiring information as to the application of the Code is requested to communicate with the Secretary of the Committee, Mr. C. W. Obert, 29 West 39th St., New York, N. Y.

The procedure of the Committee in handling the cases is as follows: All inquiries must be in written form before they are accepted for consideration. Copies are sent by the Secretary of the Committee to all of the members of the Committee. The interpretation, in the form of a reply, is then prepared by the Committee and passed upon at a regular meeting of the Committee. This interpretation is later submitted to the Council of the Society for approval, after which it is issued to the inquirer and simultaneously published in Mechanical Engineering.

Below are given the interpretations of the Committee in Cases Nos. 370 to 374 inclusive, as formulated at the meeting of October 27, 1921, and approved by the Council. In accordance with the Committee's customary practice, the names of inquirers have been omitted.

Case No. 370

Inquiry: Is it permissible, under the rules in the Boiler Code, to construct a boiler drum, 36 in. internal diameter, built with the shell in one sheet, $^{13}/_{16}$ in. thick, with one longitudinal seam having butt straps $^{1}/_{2}$ in. thick on each side? Information is also requested as to the maximum allowable working pressure as determined by the efficiency of the longitudinal seam and the tube-hole ligament.

Reply: It is the opinion of the Committee that a boiler drum constructed as described does not conform to the requirements of Par. 19 of the Code. The Committee is not in a position to determine the maximum allowable working pressure for constructions not permitted by the Code and would recommend that the question be taken up with the state authorities or insurance companies interested.

Case No. 371

Inquiry: Is it permissible to construct vertical fire-tube boilers of either the through-tube or submerged-tube types with the tubes welded in both the upper and lower tube sheets?

Reply: It is the opinion of the Committee that Par. 250 was not intended to forbid rolling and welding at both ends of the tubes of a fire-tube boiler, when desired.

Case No. 372

Inquiry: An opinion is requested as to the actual distance above tubes at which the fusible plug should be inserted in economic-type boilers under the requirement of Par. 430*r*. Is 1 in. above the upper row of tubes sufficient?

Reply: It is the opinion of the Committee that, as this type of boiler is quite similar in construction to an h.r.t. boiler, an elevation of the fusible plug 2 in. above the upper row of tubes will be necessary to meet the requirements of Par. 430*r*.

Case No. 373

Inquiry: Will the rules in the Boiler Code for calculation of the Adamson type of furnace apply to the design of conical furnace shown in Fig. 20, using the mean diameter of the cone as the nominal diameter of the furnace, and is it permissible in such construction to form the two vertical seams therein by autogenous welding?

Reply: It is the opinion of the Committee that Par. 231 covers the construction described. Autogenous welding is not permissible in this type of boiler, except in those portions of the furnace which are to be stayed.

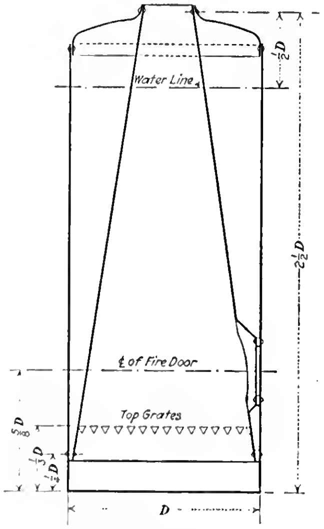

Fig. 20 Design of Vertical Boiler with Continuous Unstayed Conical Furnace

Case No. 374

Inquiry: Does the requirement of Par. 256 of the Code, relative to the term: "machine driven," refer solely to hydraulic or other forms of pressure riveters, or will pneumatic riveters conform to this requirement?

Reply: It was the intent of the Committee that the term: "machine driven" should apply only to those types of riveting machines which are able to drive the rivets with sufficient pressure to fill the rivet holes and allow them to cool and shrink under pressure.

Methods and Results of the Unemployment Conference

THE management of The Unemployment Conference called in Washington September 26, was clearly enough in the hands of a man of scientific training and practical experience, whose mind would not rest content with the convenient superstition that if a considerable number of men and women are called together and allowed to simmer, something first-rate must happen somehow. He knew that merely jumbling together some sulphur and charcoal and ammonia water never made aniline dye, not even if you stirred them with a stick—that the mere presence of the elements of a successful conference would not guarantee success. Its possibilities and impossibilities he assayed in advance, and planned and managed the job with the cool scientific purpose of getting for the country the maximum practical results. Best of all there was no belief that by some magic a lasting socio-economic influence could take form from a few weeks of conference, no matter how well managed. Hence, the several projects which the conference started are being persistently followed up by individuals or small committees under the leadership of the Department of Commerce.

Henry S. Dennison

The Conference had two principal fields of work, the curative and the preventive. It had to accept the fact that we were in an economic mess and propose measures by which we might tide ourselves over or pull ourselves out of the emergency; and it had to search out every kind of influence which might help in keeping us from getting quite so deep into the same kind of mess again.

Emergency measures were studied first, and preliminary findings were made with remarkable speed. Through its command of the counsel of men of prior experience and by promptly dividing its work among relatively small committees, the conference was able within a very short time to formulate a close approach to standard practice in the work of employment bureaus and relief agencies, which most communities are undertaking this winter. By placing the responsibility for the institution of such work upon the mayors, a perfectly specific record of accomplishment and follow-up was made possible; and the conference was no sooner over than Colonel Woods devoted his whole time to this service. Where jobs are scarce and we run into the second winter of unemployment, intelligent forehanded placement and relief will in no inconsiderable number of cities make all the difference between order and lawlessness.

While the results of the Conference in providing more jobs than would otherwise have been available must have been small, here again its greater effectiveness lay in an intimate follow-up of the public announcements. Members of the Conference and notably one president of a large employers' organization, backed up the spirit of the Conference by taking up very definitely with individual concerns the necessities of doing as much repair work, advance construction and making-to-stock as good business principles would allow, and the advantages of distributing the burden of idleness among their employees by rotation of jobs and part-time work. The same definite sort of follow-up resulted in the clearance of hundreds of State and Federal projects already acknowledged to be worth undertaking but hung up for some reason or other.

The very sense of inadequacy which any thorough exploration of the field of emergency work must arouse was a good preparation for the members of the Conference in undertaking the tasks of more permanent importance. So far the business world as a whole has seemed content to accept constantly recurring periods of inaction following periods of scarcely less expensive feverishness as visitations of any angry economic Jehovah. As yet only the pioneer bits of research into the complex of causes of the business cycle have been completed. As a result of the Conference there will be carried on during the next six months an investigation of causes more expert and extensive than has ever before been attempted. If it fails to discover our economic rats and fleas, or our commercial anopheles, at least it will come near enough to it to excite a scientific curiosity which will not be allayed.

It is not an unreasonable supposition that the exaggerations of prosperity and depression which are the source of our greatest damage might be laid largely to the present necessity of business concerns going it blind, without some of the data essential for their continuous guidance. In making definite recognition of this the Conference gave a fresh spur to the projects of the Department of Commerce and a fresh inspiration to the various trade associations to give us pertinent and prompt statistics.

In the field of government, fruit of the conference is already apparent in the Bill (Senate 2749) offered by Senator Kenyon to encourage and provide for reservation of a part of the public works determined upon and appropriated for during prosperous times to furnish worth-while work during times of depression. This will withdraw some government projects from competition in a crowded and high-priced market, to the advantage of the business and laboring community and of the government as well.

Besides the unemployment due to cycles the Conference paid attention to seasonal unemployment, and in the same spirit refused to bow to the God of Things As They Always Were. For the diagnosis of this continuous industrial sickness the managers of the conference recognized that each industry offers a problem of its own, so provided special committees to make the long study of possibilities in building trades and mining industries which is necessary before any significant suggestions for improvement can be hoped for.

In addition to all these projects the Conference undertook to put through to a point of real accomplishment a consideration of the relation of unemployment to the railroad problem, to foreign trade, and to shipping, and a statistical resurvey of the extent of unemployment. One has only to appreciate the variety of temperaments and trainings which had to be gathered together in the men and women who had done enough thinking on this formidable list of projects to have definite and individual points of view, to realize that such a group of folk plunged into open meetings would have met certain failure. Points like this were thought out in advance. The Conference therefore, was divided immediately into committees of workable size, each of which got down to the special problems prepared for it in preliminary form by an Advisory Committee appointed three weeks before the

Conference met, and began to grind itself into bearing with greater or less speed, depending upon the skill of its chairman. But this method would have lost a public interest of very great value by lack of news material, so public hearings were held beginning the second day, at which the problems of each committee were taken up in turn. When the conference as a whole was ready to meet there had already been accomplished by these methods so much adjustment of points of view and so much broadening of the understandings of the precise nature of their problems that it was easily possible to find ground for unanimous declarations of the general principles governing the various phases of the problem.

There were still left very fundamental differences of opinion as to the applications of these principles, as it was foreseen that there must be in any such gathering. By the traditional method of letting such Conferences run, these fundamental differences, being largely temperamental or environmental, and thus nonjudiciable, would have materialized into long speeches seasoned with some bitterness; and then the magical ceremonies of nose-counting would have been invoked. Now the Conference was clearly not a legislative body. Mr. Hoover had coolly estimated what it was and was for and in what ways it could serve the country. He knew that people might well be influenced by the unanimous opinions of such a group of thoughtful people, but that on any question upon which members of the conference differed, the public would first want to know who believed thus and who so. Therefore such measures as the committees failed to agree upon were presented to the country through reports signed by those whose views they represented; and matters that had been so threshed out as to constitute a final coördination of the wide range of experience represented at the Conference, were given form as unanimous declarations.

This sounds simple enough in the telling; but actually the whole procedure was a case of thoughtful and ingenious development of the technique of such conferences which, so far as I know, sets a new standard. With such an example behind us there is no more need for our making the mistakes we have made in the past in such matters than there would be for a railroad constuction engineer now to lay out curves sharper than his locomotive trucks could negotiate.

The engineering profession can find much of interest in the final accomplishments of the conference, especially when the standing committees complete their assays of the serious conditions in great seasonal activities like building and mining; but the profession cannot afford to be less interested in the example of sound social engineering which the method of management of this Conference affords. Our social structure has grown in complexity well beyond the abilities of any one or two men to chart its proper courses. We shall need more of such conferences. And it is well that an engineer has come to judgment, that they may be managed with an appreciation of the real forces and opportunities involved in them.

Henry S. Dennison.[1]

The Unique Opportunity of the Railroad Professional Division

Every individual in the land is dependent upon the power that pulls trains. In fact, the progress of the nation and the progress of transportation are inseparable. Our Society offers means for record and for discussion of developments in the application of power and equipment for transportation. This places before the Railroad Professional Division of this Society a remarkable opportunity.

Inspirations are coming from all directions, from railroad officers, from engineers connected with the builders of railway equipment, and from engineers who are in the service of companies not directly connected with the railroads or with the builders of cars or locomotives.

Wonderful results have already been obtained and even greater results are in sight, having in mind the development of electric power for transportation, steam power and equipment to carry loads, both passenger and freight. Problems are repeatedly coming up for discussion, the solution of which with the highest of efficiency will depend very largely upon the getting together of all the engineers who are devoting their lives to this progress. Our Society offers the only forum for these studies and discussions which are so important to us all.

Electric-locomotive and steam-power developments are coming on apace. Electric applications are progressing and improvements are being made. Steam locomotives have been improved and the present generation of engineers has brought to the steam locomotive improvements which were not dreamed of fifteen years ago, and the possibilities of which are not yet apparent to even railroad officials at the present time. Improvements now under development promise even greater efficiency in the steam locomotive than has ever yet been obtained.

Electricity and direct steam for railroad transportation are in competition. It is most important that those who are devoting their attention to the development of the steam locomotive should thoroughly understand what electricity is doing. On the other hand, it is equally important that electrical engineers should know that the steam locomotive of today offers possibilities that are far beyond those of the steam locomotive of ten or more years ago, and that the railroads have before them more improvements in their steam power than they have ever used. In other words, the steam locomotive as we know it right now is very different from the one we knew a few years ago.

Moreover, in a few years, if full advantage is taken of the possibilities of increasing the power per pound of weight and the power produced by a pound of coal, the steam-locomotive figures which we are now talking about will of necessity be changed. This Society offers the means for bringing out the best and latest facts regarding these developments, and of bringing together the men who know these problems. It provides the means for using to advantage the mature thought of the best engineers of this country, which of all countries is most indebted to transportation and which depends most upon transportation for its future. No other organization of engineers provides such means for getting these authorities together for mutual understanding.

G. M. Basford.

The Relation of the Engineer to the Community[1]

As GOVERNOR, the elected head of a state government, there are two angles of this question to which for a few minutes, I might call your attention. One is the practical side, simply a list of those positions in our state government which must be filled by competent engineers. Upon this I shall only dwell for a moment.

I do wish to say, however, that the State of Connecticut is proud of its Highway Department, and that this department is purely an engineering proposition. The splendid development of the road system in Connecticut is due to the work's having been done by engineers without the help of the politicians.

Our Rivers, Harbors and Bridges Commission, appointed primarily to build the million-dollar dock at New London, had and has largely engineering problems for its consideration.

Among the duties of the Shell Fish Commission are the locating and bounding of the oyster-bed leases by the state, and the engineer is a leading personality in their work.

Bachrach

Everett J Lake

The law itself requires that three of the six members of our Pollution of Streams Commission shall be engineers.

In our Department of Health the work of the engineer is as much needed and as quickly required in the case of health dangers as is that of the physician.

---

[1] President Dennison Mfg. Co.

[1] Address of the Governor of Connecticut at a banquet of The American Society of Mechanical Engineers, Hotel Bond, Hartford, Conn. Nov. 3, 1921.

It is in the Engineering Department of the Public Utilities Commission that their most numerous personnel appears.

But I will not continue a catalog of those public offices in which trained engineers must of necessity serve. I will, however, speak of what I shall call the academic angle of my subject.

There are certain fundamental characteristics of a successful engineer, characteristics which he does and must apply to his profession if he be worthy of bearing the name of engineer, and I wish to urge upon you your duties as citizens to apply them in your consideration of the problems of good government and the public weal.

Today we often hear the expression, "Government needs the business man in public office," and if this be true, the need is emphatically for the engineering qualities of the business man.

The first qualification of an engineer is concentration. He must focus on his problem like a burning glass, and not study with the eye and mind of an impressionistic artist.

The next qualification is the power of analysis. The real analytical engineer does not tear apart with ruthless hands and throw into the scrap heap all that comes between him and the point of his ultimate investigation. He rather lays aside in an orderly and tabulated array the covering or by-products, if you will, that they may be again replaced if necessary, or perhaps put to other profitable use.

The third qualification of an engineer is his power of continued application. He learns to work continuously and laboriously.

And a fourth characteristic of the engineer is the quality of thoroughness. He must in his task, in his problem, bring it to completion. A half-finished job is in his domain practically nothing done at all.

These, then, are the fundamentals of a successful engineer, and if he but avoids the one danger of his profession—that of allowing his concentration to restrict his vision, so that in the intense application to any one problem he does not see its full scope or misses an opportunity waiting at his very elbow—he becomes an ideal citizen and one of the great assets of a nation.

You engineers apply these qualities to your life work; I am asking you tonight that you give a little of them to your duties as citizens.

I read recently Fiske's opening chapter of the Beginnings of New England, wherein he describes the growth and transitions of governments.

First the oriental or ancient governments, where a conquering monarch by warfares and struggles conquered and enslaved; then through the Roman Empire and the Holy Roman Empire, when powerful rulers and governments absorbed by conquest but granted citizenship.

Through all of these years, these centuries, we find the people of the world receiving their rights, their liberties, as grants from rulers, expanded or contracted at the will of some individual monarch, or his appointed or self-appointed minister.

Then came those long years of struggle in northern Europe where men were learning self-government and applying that knowledge. One of the hardest lessons to learn was that of delegating governmental functions and yet holding their public officials from transferring their delegated power into personal authority.

With the birth of the United States at our Revolutionary War, the rule of the people was forever established. Forward has been our march both in knowledge of how to govern and our ability to apply that knowledge. So today we who are holding office are but your delegates to turn your desires, your determinations, into laws and enforcements. So, I say it is the duty of all engineers to give a little of their ability, which has made them successful, a little of their time, perhaps an hour every day, to the duties of citizenship.

There are many engineers with all the qualifications of ideal public officials who, when asked to serve, say, "I haven't the time to do it;" what they really mean is that they have not given the time to prepare themselves to do it.

No matter how successful you are in your own business, you cannot be true and square and fair to the state if you cannot or will not take time to study its problems and know what its public officials are doing. With the same technical skill which the engineer, the inventor, the surveyor, the mechanic, puts into his own profession, it is his duty every day to study public life and public affairs so that if the time comes when he is needed by the state he will be prepared for this work.

With the same concentration, the same analysis, the same determination, the same thoroughness that you study and solve the problems of a big machine, a railroad, a river, or an excavation, study and solve the problems of government, municipal and state, and you will provide better than any other class of men a solid, firm foundation for good government. And then with all of our citizenship, see that there is erected upon this foundation a structure of government clean and pure to look at, strong and firm to hold.

Everett J. Lake.

The Metric Controversy

Attention is called to the report recently issued by the National Industrial Conference Board on the Metric Versus the English System of Weights and Measures, and commented on elsewhere in this issue of Mechanical Engineering.

A committee representing interests favoring and opposing compulsory metric legislation in the United States have prepared a document which presents the facts regarding this subject in a manner worthy of careful consideration by the entire engineering profession.

The report covers the history and present status of systems of weights and measures in this country, outlines the uses of the metric and English systems in this and other countries and in special fields, and closes with the arguments for and against the substitution of the metric for the English system in the United States.

The report is indeed a notable work and the National Industrial Conference Board is to be highly congratulated for having made such a research and such a well-directed effort in presenting to the public a document of this character. It should do much to clear up the present misunderstanding regarding the controversy, which hinges on the compulsory adoption of the metric system rather than upon the merits of the metric system itself.

Calvin W. Rice.

Resolution to Prof. W. F. Durand

At a meeting of the Board of Trustees of the United Engineering Societies held in the Engineering Societies Building, New York, on November 22, a resolution was presented to Prof. W. F. Durand expressing appreciation of his services in connection with the International Engineering Congress of 1915. This Congress, held September 20–25, 1915, during the Panama-Pacific International Exposition at San Francisco, Cal., was sponsored by the following societies, the signatures of whose presidents were affixed to the resolution: American Society of Civil Engineers, American Institute of Mining and Metallurgical Engineers, The American Society of Mechanical Engineers, American Institute of Electrical Engineers, and Society of Naval Architects and Marine Engineers.

Professor Durand, as chairman of the Committee of Management, assisted by representatives of the societies sponsoring the movement, made all the necessary arrangements for the Congress, which entailed a large volume of work extending over several months. It is estimated that altogether some 750 possible authors of papers or discussions were corresponded with. Papers in foreign languages had to be translated, and papers and discussions had to be edited and revised for publication in proceedings of the Congress, which consisted of ten volumes.

The work of printing and distributing the volumes was partially completed in 1915 but distribution, especially in Europe, was delayed during the war. Professor Durand has carried on the work during these intervening years so that it is now completed and the surplus papers and volumes have been transmitted to the Engineering Societies Library.

The resolution to Professor Durand states, in part, as follows:

"The proceedings of the Congress, issued under your auspices, have come to be recognized as authoritatively portraying the status of engineering practice; and the engineering profession owes you this expression of gratitude for your enterprise, zeal, industry, and patience in the consummation of the work of the International Engineering Congress" held in the year 1915.

Marshal Foch Honored by Four National Engineering Societies

Honorary Membership Conferred upon Ferdinand Foch, Marshal of France, by Civil, Mining and Metallurgical, Mechanical and Electrical Engineering Societies at Joint Meeting in New York, December 13, 1921

IN recognition of his unparalleled service to mankind, Marshal Ferdinand Foch has been unanimously elected to honorary membership in the American Society of Civil Engineers, the American Institute of Mining and Metallurgical Engineers, The American Society of Mechanical Engineers, and the American Institute of Electrical Engineers. The presentation took place in the Auditorium of the Engineering Societies Building, 29 West 39th Street, New York, N. Y., on the afternoon of December 13, the day before Marshal Foch sailed for France.

J. Vipond Davies, president of the United Engineering Society, and presiding officer of the meeting, stated the purpose of the gathering and outlined briefly the organization of the four societies and of the United Engineering Society. Col. William Barclay Parsons, commander of the first engineer regiment to go abroad, delivered a brief address in French, expressing the appreciation of American engineers for the incomparable services rendered by Marshal Foch. He said, in part:

"The art of engineering was defined a long time ago as 'the art of directing the great sources of power in nature for the use and convenience of man.' No better definition can be found today. Of all the sources of power in nature, the greatest, the most valuable, and at the same time the most difficult to direct, is the energy of man himself. He who can direct human energy and turn it to the service of mankind is a great engineer. You, Marshal, have directed a greater mass of human energy than any other man has ever done. And you have successfully directed this mass for the highest uses of mankind, in that you by its aid have preserved for him one of the most precious of human possessions—liberty! Liberty not only for your own illustrious country, but for all the nations of the world."

THE FOCH MEDAL

FERDINAND FOCH, MARSHAL OF FRANCE

George S. Webster, president of the American Society of Civil Engineers then made the presentation of one engrossed certificate of honorary membership in all the societies, jointly, and of a case containing emblems of the membership in four societies. In his response, delivered in French, Marshal Foch praised the work of engineers during the war, stating that in moments requiring decision, "the engineer stood out as an essential factor in complete triumph," and expressing his gratitude and that of France for their services. The ceremonies closed with the presentation to the presidents of the four societies of silver replicas of the Foch medal.

This signal honor, the only one of its kind ever to have been conferred, expresses the recognition of these four great societies aggregating a membership of some 45,000, of the ability of Marshal Foch to supplement his military genius with the effective coöperation of the commanders of the armies of five nations and the coördination of their operations that won the war. It forms another bond of union between the engineers of the United States and those of France.

Marshal Foch studied engineering in l'École Polytechnique and l'École d'Application d'Artillerie. He served on the technical section of the Ministry of War early in life, and later was a full professor in l'École de Guerre. The fact that he was not only trained in the applications of engineering to military purposes, but has also taught some of these branches in France's notable war schools and practiced them in the field made him eminently fitted to be, first, Generalissimo of the Armies of the Allies, and later Marshal of France. The victory in which he played so large a part has well been given the name "Victoire de Foch."

Marshal Foch has received many honors. On November 21, 1918 he was elected a member of the French Academy. On the first of December of that year he received the Order of Merit from the King of England and in July, 1919, was given the title of Field Marshal by the King, this being the first instance in which a Frenchman's name was ever inscribed on the active list of the general officers of the British Army. During his recent tour of the United States, city, state and national organizations, educational, governmental and industrial bodies, have united to do honor to the world's greatest soldier.

Announcements of the DeLamater Ericsson Tablet Committee

At a meeting of the DeLamater Ericsson Tablet Committee held November 10, representatives of the twenty societies who have participated in the movement to commemorate the work of Mr. DeLamater and Captain Ericsson were informed of the activities of the Committee to date, and were requested to offer suggestions as to a further program. Those present were requested to have their respective organizations appoint representatives with authority to add to their number as needed to coöperate with the Tablet Committee in developing the tentative program for the ceremonies to occur on March 9, the 60th anniversary of the battle of the *Monitor* and the *Merrimac*. This larger Committee will formulate the details of the final program.

The four tablets which have been designed to mark the sites of the Phoenix Foundry, Captain Ericsson's residence, the DeLamater Iron Works, and the Continental Iron Works, will be unveiled at simultaneous ceremonies taking place on the afternoon of March 9. In the evening there will be a public meeting in a hall or a public dinner in a hotel where addresses will be made.

At the annual dinner of the Capt. John Ericsson Memorial Society of Swedish Engineers, held at the Engineers' Club November 26, Mr. Olaf Rodhe, who had just arrived from Sweden was present and stated his authority to represent the Swedish Engineering Societies of Stockholm in arranging for the celebration on March 9.

"Mining and Metallurgy"

Mechanical Engineering extends its congratulations to *Mining and Metallurgy*, admiring as it does its new dress and splendid editorial discussion of timely economic and engineering topics. The presentations are such that a member of the A.I.M.E. is put in touch not only with affairs within the Institute but with what is going on elsewhere in the engineering world, and through these contacts he finds himself in step with the onward march of his profession. Mechanical Engineering wishes its contemporary every success.

The "Scientific American"

The new monthly *Scientific American*, a combination of the former weekly *Scientific American* and the *Scientific American Monthly*, show that the best features of the former publications are being combined in the single journal. As a periodical in which both layman and professional scientist will be interested, it contains leading and short articles covering a wide range of subjects, touching on the new and unusual things in scientific discovery in all parts of the world. It contains special departments, among which are several on inventions and patents, mechanical and electrical, engineering, and science notes. The pictorial method of presenting facts, has been retained.

Index to Volume 43 of Mechanical Engineering

An index to Volume 43 of Mechanical Engineering is now in the course of preparation, and, it is expected, will be issued the latter part of February. A copy of this index will be sent to each member of the Society or subscriber who sends in a written request therefor. In order that no more copies than are necessary to supply the demand may be printed, requests for copies should be received at headquarters not later than February 15.

The Late Sir Charles Douglas Fox

Sir Charles Douglas Fox, upon whom in 1900 was conferred honorary membership in The American Society of Mechanical Engineers, died on November 13, 1921, at the age of eighty-one. Sir Douglas received his early education at the Cholmondeley School at Highgate, studied at King's College, London, and at the age of 17 was apprenticed to his father, Sir Charles Fox. For two of these apprenticed years he acted as resident engineer in charge of work upon the Witney Railway, and subsequently was with the Ramsey Railway in the same capacity. In 1863 he joined his father's firm as a partner; later his brother, Sir Francis, became a partner, and ultimately the name of the firm was changed to Sir Douglas Fox and Partners, of which firm he was the head at the time of his death.

Sir Douglas Fox's work covered a wide field, for his name was well known in connection with the construction of railways in South Africa and Australia as it was in England. Among his earlier work was the construction of the London, Brighton and South Coast Railway, the Cape Town and Wellington Railway, and the Cape Town-Wynberg Railway. With Sir James Brunlees, he acted as consulting engineer for the Mersey Tunnel. For his work in this connection Her Majesty Queen Victoria conferred the honor of knighthood upon him. He was also connected as joint consulting engineer with the construction of the Liverpool Overhead Railway. This work is unique in England, though on lines similar to the elevated lines in New York City. Sir Douglas and his brother were responsible for the engineering work on the Southern and Metropolitan divisions of the Great Central Railway. He also took a prominent part in underground-railway development in England. In Africa his name is associated with the Rhodesian Railway and the famous bridge over the Zambesi River at Victoria Falls. Other undertakings in South Africa were the Beira Port and Railway, Benguela Railway and the Trans-Zambesi Railway. In South America he was responsible for the construction of railways in the Argentine for the Central Argentine Railway Co.; in Colombia, for the Dorada Railway Co., and also in Brazil.

Sir Charles Douglas Fox

He was an enthusiastic advocate of standardization and was one of the early supporters of the movement which resulted in the formation of the British Engineering Standards Committee in 1901 on whose main committee he served from the time of its formation till early in 1920.

Sir Douglas Fox became a member of the Institution of Civil Engineers in 1866, was elected to the council in 1884 and served as its president in 1899–1900. During his term of office he received the American civil and mechanical engineers, who were entertained at the Guildhall on the occasion of their visit to London that year. He was also a member of the Institution of Mechanical Engineers, the Institution of Electrical Engineers, and an honorary member not only of The American Society of Mechanical Engineers but also of the American Society of Civil Engineers. He was a director of some ten companies, was vice-chairman of the South Indian Railway Co., and chairman of the Industrial Dwellings Co. and of the Northfleet Coal and Ballast Co. He patented numerous inventions connected with railway work. In 1880 he was appointed lecturer to the School of Military Engineering, Chatham, his lectures dealing with light and temporary railways. He was awarded at various times by the Institution of Civil Engineers the Manby Premium, the Telford Medal, and Telford Premium for contributions to the proceedings. He was elected a Fellow of King's College (London) in 1887. He was a justice of the peace and took a prominent part in many of the religious and philanthropic movements of the day.

NEWS OF THE F.A.E.S.

January Meeting of American Engineering Council

The annual meeting of the American Engineering Council will be held in Washington January 5 and 6. Details of this meeting are not yet available, but the program will include matters pertaining to organization, a review of the past year's activities, and decisions as to future policies. The question of finances will receive special consideration. A recently issued résumé of the activities of the Executive Board stated that although at the time the annual budget was adopted information as to probable expenditures for the fiscal year was necessarily very incomplete, and although unusual demands have been made upon the treasury, the Board has been able to function within the limits of its resources. It has been found, however, that even the moderate dues required for membership have been so high as to prevent several organizations from becoming members of the Federation.

Employment Service

In accordance with a resolution passed at the September meeting of the Executive Board a joint committee of nine, consisting of five members of the Executive Board and a representative from each of the four national engineering societies, has been appointed with power to organize uniform paid employment service for engineers. The members of this committee are as follows: Morris L. Cooke, Chairman, William McClellan, W. E. Rolfe, H. E. Howe, and William B. Powell, of the Executive Board; Richard L. Humphreys, A.S.C.E.; W. M. Corse, A.I.M.E.; Fred J. Miller, A.S.M.E.; and E. B. Craft, A.I.E.E.

The Executive Board has also voted a special appropriation of $2000 for emergency employment work.

Engineering Education

The Executive Board has received several communications relative to the subject of engineering education. The University of Iowa recommended that the American Engineering Council "establish standards of engineering education for engineering colleges of different grades and rate the engineering colleges of the country in accordance with the classification adopted." A resolution by Mr. W. W. Varney of Baltimore, a member of the Executive Board who has been among those taking a deep interest in engineering-education policies, asked that the Federation appoint "a Committee on Education to consider broadly the training of the engineer and to report on desirable changes in present-day engineering education to better prepare engineering graduates to take their proper places in the profession." Because of these requests, although the Board felt that there were other organizations more directly affected by and concerned with these matters that are giving consideration to them, it has decided to institute appropriate inquiry through a special committee on engineering education. The Committee on Procedure has accordingly appointed Col. A. S. Dwight of New York, Prof. Chas. F. Scott of Yale, and Mr. Varney to study the problem and work out a policy for the F.A.E.S.

Errata

In the paper by Dr. D. S. Jacobus on Boiler and Furnace Economy in the December issue, the temperature mentioned in the fifth line of the third paragraph from the bottom of page 782 was erroneously stated to be 500 deg. fahr. It should read 300 deg. fahr.

The November issue of Mechanical Engineering contained an account of a recent snow removal meeting of the Materials Handling Division of the A.S.M.E. in which there were some erroneous statements concerning a device evolved by Edward A. Smith of West Englewood, N. J. The size of the melting chamber of this machine is 67,400 cubic inches instead of cubic feet. Mr. Smith states that at 30 cents per cu. yd., a price which has been paid by the city of New York, it would cost $2,220,000 to remove 7,400,000 cu. yd. of snow, representing an 8-in. fall on approximately 33,000,000 sq. yd. of streets, whereas by using 100 of his machines, and working 28 hours, this amount of snow could be melted for $28,000, including the total operating expenses.

NEWS OF OTHER SOCIETIES

National Founders' Association

The twenty-fifth annual convention of the National Founders' Association was held in New York on November 16 and 17, 1921. At the opening session, President William H. Barr discussed the industrial situation and general causes of present conditions, and A. E. McClintock, commissioner of the association, urged training of forces for future expansion of industry, instruction of employees in principles of economics, and development of a spirit of loyalty within industrial organizations.

Among the speakers at the afternoon session, November 16, were Magnus W. Alexander, Mem.Am.Soc.M.E., on Wage Liquidation in American Industry, and A. C. Davis, on The Present Railway Situation. Mr. Alexander presented charts showing changes in wage rates during recent years, hours worked, percentages of employment, etc., with special reference to foundries and machine shops. These charts are based upon investigations conducted in over twenty industries by the National Industrial Conference Board, of which Mr. Alexander is managing director.

Mr. Davis, vice-president of the Gurney Ball Bearing Company, traced the development of the railroad and discussed some of the measures wherein he believed the solution of some of the present railway problems might be found.

On the second day of the conference the following addresses were presented: Foreman Training, L. V. Hartley, and Foundry Costs, Robert E. Belt. Mr. Hartley, of the Department of Vocational Education of the State of Nebraska, described the project method of training foremen used in that state and showed charts indicating savings in operation costs resulting from the installation of foreman-training courses in various plants.

Mr. Belt, who is secretary-treasurer of the American Malleable Castings Association, gave a paper which dealt with foundry costs, pointing out the importance of an accurate and uniform system and giving the relation of cost to selling price.

An extemporaneous speaker on the first day of the conference was Governor Henry Allen, of Kansas, who gave a brief history of the Court of Industrial Relations in that state. He stated that of the thirty cases decided by the court, twenty-nine have been satisfactory to both employers and labor.

The convention addressed a resolution to the United States Senate urging that railroad regulation be handled by a public tribunal and emphasizing the importance of adjusting all problems without stoppage of service.

American Iron and Steel Institute

A memorable meeting of the American Iron and Steel Institute was held in New York on Friday, November 18, 1921. The opening address by Judge Gary, president of the Institute, discussed business conditions, expressed his endorsement of limitation of armament and prophesied prosperous business conditions in the comparatively near future.

Six papers were presented at the professional sessions. John W. Kargarise, of the Edgar Thomson Works, Carnegie Steel Co., Braddock, Pa., discussed improvements in open-hearth port construction, describing early types and giving some of the results of the McKune system and the Venturi and Egler furnaces.

James M. Camp, director of the Bureau of Technical Instruction, Carnegie Steel Co., Pittsburgh, Pa., outlined the relations of the iron and steel and chemical industries.

Thomas J. Foster, chairman of the National Bridge Works, Long Island City, explained the formation of steel lumber and described various types used for building construction. He enumerated the characteristics of steel lumber which make it economical and described tests to which it has been subjected. He stated that residence work, including apartments, is twenty per cent of the total building of this country and that with an ideal steel joist a large share of these structures will be built of steel at a material reduction in price.

Fusion Welding and the Processes in Use were described by S. W. Miller, president of the American Welding Society. He gave the composition of low-carbon steel wire used for gas-welding steel and also of wire for electric metallic-arc welding. Among causes of failures in welded parts he spoke of lack of fusion, both along the

side of the V and in the weld metal itself, and also of the oxidizing action of the water vapor in the gas welding flame and that of the air on the finely divided metal passing through the electric arc. He was of the opinion that nitrogen has no serious effect so far as tensile stress is concerned but that brittleness of welds is due to the presence of oxides.

W. A. Hull, chief of the Refractories Section of the Bureau of Standards, in a paper on Refractories in the Steel Plant, made a strong plea for adequate specifications and coöperation between producer and consumer. A. E. Bourcoud, consulting engineer, New York, discussed a direct process for steel manufacture.

The meeting closed with a banquet in honor of Marshal Foch, at which there were many distinguished guests. After-dinner speakers, besides the guest of honor and President Gary, were Charles M. Schwab and W. D. Guthrie.

Society of Naval Architects and Marine Engineers

The Society of Naval Architects and Marine Engineers held its twenty-ninth general meeting in New York Thursday and Friday, November 17 and 18, 1921. Thirteen papers were presented at four professional sessions. One of these sessions was a joint meeting with the American Institute of Electrical Engineers, at which W. E. Thau, general engineer for Westinghouse Electric & Manufacturing Company, East Pittsburgh, Pa., presented a paper on Electric Propulsion of Ships, and E. D. Dickinson, mechanical engineer of the Marine Department of the General Electric Company, Schenectady, N. Y., spoke on Electric Auxiliaries on Merchant Ships.

Among the subjects discussed at other sessions were The Tactical Relations between Different Classes of Men of War and Their Embodiment in Design; Development of the Three-Plane Navy, With or Without Battleships; How Can American Ships Compete Successfully with Foreign Ships; The Importance of Port Facilities in the Development of Merchant Marine and Commerce; American Apprenticeships, Schools and Scholarships; and Design and Construction of Passenger Steamers.

Special arrangements were made for the convenience of those members desiring to view the exhibition of the Marine Equipment Association of America held in New York during the week of November 14–19. The most modern auxiliaries and equipment installed on board ships as well as illustrations of various new methods in shipbuilding work were displayed at this exhibition.

The Taylor Society

The Taylor Society held its annual meeting in New York, Dec. 1, 2 and 3. The first public session, held Thursday evening, December 1, was devoted to an examination of the evaluation sheet devised and used by the Committee on the Elimination of Waste in Industry. The technique of the method employed by the committee was discussed by a large number of engineers who coöperated in the investigation.

There were two sales executives' sessions on the second day of the conference, one devoted to the report of the Committee on Sales Engineering and one to a paper on the necessity of the quota for proper sales cost accounting. There was also a plant managers' session, with a paper by C. F. O'Connor, production manager of the Universal Winding Company, Providence, R. I., and discussion of maintenance of a system of operations under varying conditions by Carl G. Barth, Wilfred Lewis, William O. Lichtner, R. G. Scott, and other engineers well fitted to deal with problems of scientific management.

At an office managers' session it was shown that such fundamental principles of scientific management as precise control of routine operations, standardization the basis of control, and investigation and experiment the basis of standardization, can be applied to offices as well as shops.

The evening session on December 2 dealt with the general control of business. In a paper presented by John H. Williams, of Day & Zimmermann, Philadelphia, it was shown that any precision in general control rests upon the foundation of precision in the details of operating organization and control. This session was planned by the Taylor Society in order to bring out discussion which may be used as a guide in its study on the problem of general administrative control. This study is being conducted by a special committee appointed by the society.

On December 3 there was a plant managers' session and a labor managers' session. The first was devoted to a study of combination routing to meet the problems of small quantities and short operations. The second presented an analysis of the elements which make a good worker and of the forces which influence these elements.

The meeting closed with a luncheon in honor of Henry R. Towne, honorary president of the Taylor Society. Addresses by Mr. Towne, Wilfred Lewis, president of the Tabor Manufacturing Company, Philadelphia, and Calvin Rice, secretary A.S.M.E., were reminiscent of the early days of scientific management and of Frederick W. Taylor, of whom Mr. Towne was always a strong supporter.

RADIO SHIP CONTROL

(*Continued from page 44*)

neering. Its success was pronounced from the start, but as with the first tests of all such apparatus, it was found that some of the parts were too sensitive, and more rugged ones were developed under the direction of the officers of the Battleship *Ohio.* Simplification of the equipment was also effected in the same manner.

Economy Results

(105)	Steam less water (or superheated steam) consumed per i.hp-hr. (Item 80 ÷ Item 90)	lb.
(106)	Equivalent steam consumed per i.hp. (Item 81 + Item 90)	lb.
(107)	Steam less water (or superheated steam) consumed per 100 cu. ft. of air or gas compressed at intake pressure and temperature (100 × Item 73 + Item 67)	lb.
(108)	Equivalent steam consumed per 100 cu. ft. of air or gas compressed at intake pressure and temperature (100 × Item 75 + Item 67)	lb.

TABLE 4 ADDITIONAL ITEMS APPLYING ONLY WHEN THE DRIVING ELEMENT IS AN INTERNAL-COMBUSTION ENGINE

(The items of this table will be developed upon the completion of the Test Code for Internal-Combustion Engines.)

Metric vs. English System of Weights and Measures

Review by Luther D. Burlingame, Chairman of the A.S.M.E. Standing Committee on Weights and Measures, of Research Report No. 42 of the National Industrial Conference Board

Owing to the continued discussion of the question of the adoption of the metric system in this country, to supplant the established system of weights and measures, a joint committee was appointed by the National Industrial Conference Board to represent interests favoring and opposed to the adoption of the metric system in the United States, with the idea of making a thorough and impartial investigation of the situation, and publishing the results in order that a basis may be had for an intelligent decision not only by the affiliated organizations making up the National Industrial Conference Board, but by the public at large. The following Committee has served:

E. M. Herr, *Chairman*, president of the Westinghouse Electric & Mfg. Co.

Fred J. Miller, past-president of The American Society of Mechanical Engineers

Henry D. Sharpe, treasurer, Brown & Sharpe Mfg. Co.

Henry R. Towne, chairman of Board of Directors, Yale & Towne Mfg. Co.

Frank O. Wells, formerly president of the Greenfield Tap & Die Co.

Under the supervision of this Committee the investigation was carried on through trained employees of the National Industrial Conference Board, and has resulted in the publication of a report of 261 pages, divided into three parts:

- I History and Present National Status of Systems of Weights and Measures
- II Use of Metric and English Systems in Special Fields
- III Arguments for and against the Substitution of the Metric for the English System in the United States.

Part I gives first the origin of the English and other natural systems, showing how our present system has developed from the needs of men, and has become adapted to fundamental trades and industries. The history of the origin and development of the metric system follows. The present status of the two systems is then compared, showing the number of countries and population of each where the English and metric systems respectively predominate, and their relative percentages to other countries where neither predominates. This analysis shows that the English system predominates in twelve countries with a population of nearly 350,000,000, while the metric system predominates in thirty-seven countries with a population of nearly 400,000,000, the combined total, however, being less than half the population of the world, this "larger half" being listed as having neither the English nor the metric system predominating.

This part of the report deals with many of the South American countries which were considered in a paper entitled, The Weights and Measures of Latin America, presented by Mr. F. A. Halsey before the A.S.M.E. at the Annual Meeting in December, 1918; and it is interesting to compare the findings of the investigators of the National Industrial Conference Board with those in Mr. Halsey's paper. While Mr. Halsey goes much more into detail as to the lines of industry and manufacture where the various systems are used, the general trend of the present report follows very closely the findings as shown by his investigation, and countries which were reported by him as showing least progress toward the metric system in actual use, are classed as doubtful.

Under the heading Weights and Measures in the United States the present situation is summarized clearly and holds the issue up squarely to the American public, as follows (page 42 of the report):

> The situation in the United States, however, is today quite different from the situation that confronted other important countries in making a change from their local systems to the metric. In other countries considerable confusion of weights and measures existed at the time the change was brought about. In other countries, also, the change took place before the industrial life of the nation had become organized and standardized to the extent that modern production makes necessary. The countries outside of Europe which have adopted the metric system have little or no organized industry in the modern sense.
>
> In the United States today there is, in the first place, no fundamental confusion with respect to weights and measures. Furthermore, the United States unquestionably stands in the forefront of the great industrial and manufacturing nations. Its highly organized industry is based on the English units of weight and measure, and most of its vast technical literature is written in this system. All things considered, therefore, there does not exist in this country the great incentive to a change found in other nations where confusion was the rule until the metric system was adopted.
>
> In consequence the situation today narrows itself down to the question whether the advantages to be gained warrant the compulsory adoption of one unified system, namely, the metric, in the place of another unified system, namely, the English, which latter is moreover the established system and enters so intimately into the present industrial organization of the nation. It is not a question of allowing the use of the two systems side by side and giving the metric the opportunity of supplanting the English, because the metric has, as a matter of fact, been a legal system in the United States since 1866, and any one who so desires and finds it more convenient and practical may use it. The question is, shall the United States discard the English system of weights and measures entirely and absolutely and in its place substitute by compulsory law the metric system as the sole standard?

The report includes arguments for making the change and the reasons on which these arguments are based. These statements with their opposing arguments are both strongly presented.

Use of Metric and English Systems in Special Fields

Part II opens with the statement that "a nation is made up of a number of special fields of activity, in which the question of a change in weights and measures plays a little or a greater part, depending on the nature of the field and the ease or difficulty with which a change from an established to another system can be accomplished," and introduces a series of questions to be answered, such as:

1. Has a given field had its origin and development in a certain country and then spread to the rest of the world, carrying with it the weights and measures of the country of origin?
2. Does the position an industry has achieved and now holds center about standardized practices, with respect to weights and measures, built up after years of effort, and would the destruction or alteration of these practices virtually mean the giving up of the prominent place held by the industry?
3. Is the scope of a certain field limited and local, as in agriculture or mining, or international?
4. Are the weights and measures written into the very fabric of the institutions, implements or records existing in a certain field?
5. What is the relative importance of one field as against another?
6. How much demand is there for a change?

The report then goes on to analyze these various issues and to give a background, so that an intelligent answer can be given to each of these questions, under the following headings:

1 *Science and Engineering*, under which are discussed chemistry, medicine and pharmacy, electrical, mechanical, and civil engineering, etc. This division is thus summarized:

> A considerable demand for a change in systems of weights and measures in the United States comes from the scientific group and from those engaged in the manufacture of refined instruments and products, but this sentiment is not shared very much by the engineering professions......Even though this group were unanimously in favor of a change, its size is small as compared with such fields as agriculture, mining, manufacturing, and trade, and it would suffer no hardship through a change, while these others would.

2 *Agriculture, Mining, Transportation and Trade.* After an analytical and statistical discussion, it is summarized thus:

> In the four fields treated in this chapter, such little demand as exists for a change to the metric system comes from those engaged in wholesale trade, who, as has been noted, comprise a very small group, comparatively speaking. There is practically no sentiment at all in favor of a change to be found in the other fields discussed.

3 *Manufacturing*, including textiles, metal products, food products, lumber, paper and printing, leather and its finished products, etc. The summary of this part of the investigation states that:

> The survey in this chapter of various specific manufacturing industries serves to indicate how intimately weights and measures are tied up with the products of manufacture and how widely English units are used in various industries the world over.

The report cites specific instances to illustrate this, and continues:

Over 90 per cent of the metal-products industry registered decided opposition to a change. The food-products industry showed similar opposition. The lumber industry was likewise opposed and emphasized "the great confusion and incalculable expense" that would result. The paper and printing, automobile, railway car, shipbuilding, and implement and vehicle industries also went on record as decidedly adverse to any change.

The manufacturing field, employing as it does over 10,500,000 workers, and producing commodities valued at something like $25,000,000,000 annually, is unquestionably one of the most important fields of industry in the United States. The indications are that a compulsory change to the metric system would profoundly affect many manufacturing lines especially during the period of transition, which the experience of other countries suggests would be very long. The interests and desires of such an important field and the effect of a change in weights and measures upon it should naturally be carefully weighed in considering the advisability of a compulsory change.

4 *Foreign Trade.* Much attention is given to an analysis of world trade, and the arguments pro and con, as to whether a change to the metric system would be of appreciable benefit to the foreign trade of this country. The figures show that 48.2 per cent of the world's export trade is now transacted by English countries, 37.5 per cent by metric countries, and 14.3 per cent by other countries. This indicates that while more than half of the population of the world is included under the heading "other countries," the total amount of foreign trade which they represent is a very small percentage of the total.

The graphic diagrams shown in the report make very clear the relative importance of the different elements which have an influence on this discussion, and the above ratios are shown in one of these diagrams. (Page 105).

Another diagram (page 113) shows the exports of the United States to English countries as 41.9 per cent, to Latin-American English and other countries, 5.7 per cent, to European metric countries 37.1 per cent, to Latin-American metric countries, 6.3 per cent, and to all other countries, 9 pei cent.

Arguments for and against the Substitution of the Metric for the English System in the United States

Part III is in the nature of the lawyers' pleas on each side of a case before a court, and is of value as showing opposing views strongly expressed. It is divided under the headings:

1 Intrinsic Merits of the Metric and English Systems
2 Advantages and Use of Metric as Compared with the English System in Special Fields
3 Practicability of Making a Compulsory Change
4 Extent and Character of Demand for such a Change
5 Comparison of Metric and English as Universal Systems.

The arguments pro and con under these headings are presented in such a way that they are in the nature of a spirited debate, and any one who is even casually interested in great issues before this country would be not only instructed but greatly interested in carefully following the discussion. (The report may be obtained from The Century Company, New York, at $2.50 a copy.)

It is believed that with the metric question again before a congressional committee and the issue being raised before great national organizations throughout the country, a careful study of this report will help to insure sound judgment in coming to such a decision as will place the influence of the reader on the side of this momentous question where it will count to support that policy which will be for the best interests of the American people.

Waste in Industry

Waste in Industry. By the Committee on Elimination of Waste in Industry of the Federated American Engineering Societies. First edition, 1921. Published by Federated American Engineering Societies, Washington, D. C. McGraw-Hill Book Co., Inc., New York, selling agents. Cloth, 6 × 9 in., 409 pp., charts, tables, $4.

Reviewed by Joseph W. Roe,[1] New York, N. Y.

While many have been attacking the problems of waste in specific industries with steadily increasing effect, no qualified agency has heretofore attempted to do so for Industry as a whole.

One of the first acts of Mr. Herbert Hoover, as first president of the Federated American Engineering Societies, was the appointment of a committee of engineers to undertake this, and the book in hand is their formal report. The purpose was to gather concrete information, to stimulate action, and lay a foundation for other studies. No attempt was made at an academic definition of waste. It has been treated as the difference, in material, time and effort expended in production, between average practice and the best known practice; and the committee has undertaken to evaluate this difference. Its first work was to set up units and methods of measurement which could be applied to all the industries studied. This is something new and of great possibilities. With this in view a very complete questionnaire was prepared and used as a basis for a trial study of one plant in each industry. The results of these studies were brought together, reviewed by the committee and a revised questionnaire developed, which was used in all subsequent work. The quantitative comparison between different industries was made through use of a point system on "evaluation sheets," these sheets having the same grouping of information as the questionnaire, and with definite, careful instructions as to the method of arriving at the totals. The totals indicate waste in comparison with the best existing practice. Both the questionnaire and the evaluation sheets are given in full and are one of its most valuable parts of the report.

This method of rating by points supplies a common ground for the findings of 50 engineers, covering 125 plants, in 6 industries. While it cannot eliminate variations of judgment in evaluating the different elements, it makes sure that the same method is used in all cases, also that the same elements are considered and in the same relationships.

There is no hesitation in saying that the study affords the best information we have to date. It makes no claim to minute accuracy, but it does to substantial accuracy. The broad findings are summarized in the Tables 1, 2 and 3.

From Table 1 are derived percentage values for each of the agencies against which responsibility is assessed, as in Table 2.

TABLE 1

Industry Studied	Responsibility Assayed Against Management, Points	Responsibility Assayed Against Labor, Points	Responsibility Assayed Against Outside Contacts (The Public, Trade Relationships, and other Factors), Points	Totals, Points
Men's Clothing Mfg....	48.33	10.50	4.95	63.78
Building Industry......	34.30	11.30	7.40	53.00
Printing..............	36.36	16.25	5.00	57.61
Boot & Shoe Mfg.......	30.25	4.85	5.83	40.93
Metal Trades..........	23.23	2.55	2.88	28.66
Textile Mfg............	24.70	4.70	19.80	49.20

TABLE 2

Industry Studied	Responsibility Assayed Against Management, Per Cent	Responsibility Assayed Against Labor, Per Cent	Responsibility Assayed against Outside Contacts (The Public, Trade Relationships, and other Factors) Per Cent
Men's Clothing Mfg....	75	16	9
Building Industry......	65	21	14
Printing..............	63	28	9
Boot & Shoe Mfg.	73	11	16
Metal Trades..........	81	9	10
Textile Mfg............	50	10	40

TABLE 3

Industry	Points Assayed Against the Best Plant Studied	Points Assayed Against the Average of all Plants Studied	Ratio Best to Average
Men's Clothing Mfg....	26.73	63.78	1 : 2
Building Industry......	30.15	53.00	1 : 1¾
Printing..............	30.50	57.61	1 : 2
Boot & Shoe Mfg......	12.50	40.83	1 : 3
Metal Trades...	6.00	28.66	1 : 4¾
Textile Mfg....	28.00	49.20	1 : 1¾

In every industry there are outstanding examples of good management. Table 3 gives a comparison of the best plant in each industry studied, with the average of the plants.

These tables embody the general findings developed throughout the report. The results have surprised the general public, but not those familiar with management problems. Management has

---

[1] Professor of Industrial Engineering, New York University. Mem. Am. Soc.M.E.

the greatest opportunity and responsibility for eliminating waste. Labor has an important part, though smaller in proportion. The public also has a part, but less clearly defined and far more difficult to rectify. In many cases it involves change of habits and tastes. It is all very well to talk of a reduction in the numbers of styles, but only a nervy man would tell his best girl that standardization requires her to wear her last year's hat a second winter; and the worst of it is, he would quit loving her if she did.

The first of the three sections is a summary of the detailed reports, covering the sources and causes of waste, recommendations for elimination, and a description of the questionnaire and the evaluation sheet used.

The second section contains the reports of the six industries studied—the building trades, men's ready-made clothing, shoe manufacturing, printing, metal trades and textile manufacturing.

The third section comprises seven general reports, covering unemployment, strikes and lockouts, legal machinery for adjusting disputes, industrial accidents, health of industrial workers, eye conservation, and purchasing and sales policies. These are statistical in nature, but all have constructive suggestions for betterment.

This book should be read by every man in a position of industrial responsibility. It is full of matter challenging attention and maintains throughout a constructive attitude. The method of gaging wastes is especially suggestive and forms a yardstick by which a manager can measure waste in his own industry and in many cases establishes a basis of comparison which may prove a great help. The yardstick may be crude, but until a better one is devised, valuable comparative results can be obtained if everybody uses the same stick.

Book Notes

Annals of the American Academy of Political and Social Science, May 1920. Paper, 6 × 9 in., Vol. 89, No. 178. 289 pp., $1.25.

This volume of essays discusses the economic significance of present-day prices, price factors in typical commodities, wages, profits and excess profits taxes, production, coöperation, international finance and trade in their relation to prices, inflation and prices, and the world's monetary problems. The papers included are by well-known economists, business men and engineers.

Bleaching. By S. H. Higgins. Longmans, Green & Co., New York, 1921. (Publications of the University of Manchester, No. 142.) Cloth, 6 × 9 in., 137 pp., $3.75.

The idea of this volume is not to give an account of the subject of bleaching, but to act as a supplement to other books, of which there are many, dealing with this industry. The author's intention has been to discuss the important researches of recent years bearing on bleaching as a basis for further research.

Central Station Rates in Theory and Practice. By H. E. Eisenmenger. Frederick J. Drake & Co., Chicago, 1921. Fabrikoid, 5 × 7 in., 382 pp., illus.

A textbook for students of electric rates, intended to meet the needs of both beginners and experts. Discusses the cost of electric service, its price, systems of charging, rate analysis, the accuracy of rates and public regulation of public utilities. Appeared serially in the *Electrical Review*.

Centrifugal Pumps. By J. W. Cameron. Scott, Greenwood & Son, London. 1921. Cloth, 6 × 9 in., 142 pp., illus., $3.75.

This small book discusses the theory of these pumps, hydraulic losses, hydraulic efficiency, bearings, effect of vane angle on efficiency, pump details, axial thrust balancing, calculation and design of pumps, and commercial types. The work is intended for engineers and draftsmen.

Les Combustibles Liquides et Leurs Applications. By the Syndicat d'Applications Industrielles des Combustibles Liquides. Gauthier-Villars et Cie, Paris, 1921. Cloth, 4 × 6 in., 621 pp., illus.

This handbook, published by an association of French companies interested in the production and use of liquid fuel, has been prepared as a practical guide to users and dealers. It includes the regulations governing the importation and use of liquid fuels, insurance laws, brief descriptions of the chief oil-producing countries, the principal fuel oils and lubricants and methods for testing them. Descriptions of the leading French types of internal combustion engines, furnaces and boilers are given, and directions for storing and shipping oil. The final section consists of conversion tables and coefficients.

Condensed Catalogues of Mechanical Equipment. Published by The American Society of Mechanical Engineers, New York, 1921. Eleventh annual volume. Cloth, 6 × 9 in., 932 pp., illus., $4.

The eleventh issue of this convenient collection of commercial data upon mechanical equipment and accompanying directories of manufacturers and consulting engineers follows the form of preceding editions. It has, however, been enlarged considerably and revised carefully. Four thousand firms are listed, under 3000 classes, and 495 of these have published data about their products in the book. The number of consulting engineers is 1000, classified under 400 lines of specialization.

Elektrische Foerdermaschinen. By W. Philippi. S. Hirzel, Leipzig, 1921. Paper, 6 × 9 in., 304 pp., illus.

The use of electric hoisting machinery in mining is covered from several viewpoints, mechanical, electrical and economic, with special stress upon the last aspect of the question. The question, whether electric hoisting shall be adopted for a given mine, is the one to which most attention is given.

Employment Management, Wage Systems and Rate Setting. First edition. The Industrial Press, New York, 1921. Paper, 6 × 9 in., 103 pp., $1.

This concise description of systematic methods of employing and placing men, and of wage-payment systems, is based on articles that have appeared in *Machinery*, describing the practice in the Westinghouse Electric and Manufacturing Company, R. K. LeBlond Machine Tool Company, Norton Company and other manufacturing plants.

Die Forderung von Massengutern. By Georg von Hanffstengel. Vol. 1. Julius Springer, Berlin, 1921. Cloth, 6 × 9 in., 306 pp., illus., 234 M.

Volume one of the third edition of this useful treatise deals with belt, chain, bucket, screw, spiral, pneumatic and hydraulic conveyors, together with some minor types. The text is practical as well as theoretical, and covers modern practice very thoroughly. The work has been thoroughly revised.

Graphical Methods. By William C. Marshall. First edition. McGraw-Hill Book Co., Inc., New York, 1921. Cloth, 6 × 9 in., 253 pp., charts $3.

A general treatise on the construction and use of graphical charts. Includes charts intended to appeal to the general public, those of interest to executives and those intended to facilitate engineering and scientific calculations. Gives many examples of the application of charts to a great variety of purposes and contains an extensive bibliography of published charts.

Steam Road Vehicles. By L. M. Meyrick-Jones. Second edition. Iliffe & Sons, Ltd., London. Cloth, 6 × 8 in., 213 pp., illus., 5 s.

This book is intended to provide an explanation of the theory and practice of steam-road transport, suited to the needs of owners and as an instruction book for drivers and mechanics. Its twenty-eight chapters describe the principles involved in the generation of steam and the construction of the various units that make up the vehicle. This edition has been revised and enlarged. The practice described is exclusively British.

Oil-Field Practice. By Dorsey Hager. First edition. McGraw-Hill Book Co., Inc., New York, 1921. Fabrikoid, 5 × 7 in., 310 pp., illus., diagrams, $3.

The subjects treated in this volume are the acquisition of lands, development drilling, development production methods, transportation, storage, fires, avoidable wastes and losses, refining methods, valuation and buying, and general observations on the industry. The appendix contains sample forms for records, useful tables and a glossary. The book presents American methods of developing oil properties and is intended to give an intelligent insight into the petroleum industry as a whole. To a certain extent it supplements the author's earlier work, Practical Oil Geology.

COMPOUNDING THE COMBUSTION ENGINE

(Continued from page 32)

under complete control. In one instance the clutch succeeded in suppressing entirely a very serious "critical" which occurred in a 700-hp. submarine type Diesel near the normal running speed.[1]

Saving in Weight and Space over Diesels

In Fig. 13 there is shown in side elevation to the left, and end elevation to the right, the comparison between the compound divided-unit geared drive delivering to the tail shaft the same power and speed as the standard Diesel unit of the largest manufacturer. The divided unit consists of two engines, each with four combustion cylinders, in two compound units. Note each of these engines gives the same turning moments and torque diagram as an eight-cylinder Diesel. In fact, with this divided unit we have eight combustion cylinders in the two engines with less than half of the cams, etc., of a six-cylinder Diesel, with all the advantages of two engines, including immunity from shutdown, possibility of inspection and other operating advantages which are well recognized. These two views serve graphically to give some idea of the saving in weight and space.

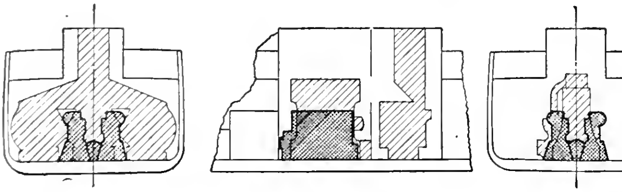

Fig. 14 Comparison between Reciprocating Steam Plant and Geared Compound Diesel Engine

To aid in the comparison with the reciprocating steam engine, Fig. 14 has been developed, giving three views of the steam plant in shaded background. Against it there is outlined the standard compound, two-engine, geared magnetic-clutch arrangement for the identical horsepower and speed at the tail shaft.

PRESIDENT CARMAN'S ADDRESS

(Continued from page 8)

Moral, the Political, and the Economic. I briefly define them as follows:

The Moral Law: God's Law, immutable, unchanging
The Political Law: Man's Law, continually changing
The Economic Law: The Law resultant from the two others.

These laws are coexisting. Their scientific application and operation is necessary, and to have an equilibrium all of them must function properly and in harmony, just as the various parts of a properly working machine must all function. There is a relationship existing between these laws just as definite as the proportional relationship existing between the elements that go to make up the strongest bar of steel, the parts of a completed machine, or the departments of a well-organized and successfully operating business.

The Political and Economic Laws *must* conform to the Moral Law, it is the basic law—and only in this way will complete harmony be secured. These three laws have all been and are in continuous operation but they fail to function as a unit, and their independent operation has produced the chaotic conditions existing today.

There has been much effort in the last decade to solve the problems of so-called "Industrial Relations." Many plans have been advanced and tried, and while there has been some improvement, nevertheless these plans have fallen far short of their goal. Let me lay special stress on this fact, for any effort and endeavor is predestined to failure unless its fundamental principle conforms to each and all of these laws. The world has been asking for thousands of years, "Am I my brother's keeper." The answer comes back through the ages, "Yes," "Love thy neighbor as thyself."

What is the remedy? There must be a speedy adjustment of affairs vital to mankind; we must secure a recognition of and obedience to all of these laws or we will soon be in the midst of the greatest conflict of all ages. We are only just beginning to admit that here is the source of most of the difficulties that we have today.

If civilization is to continue, and I am sure it is, this complete conformity must be sought for, found, accepted, and reduced to practice. If the search is not to be made by engineers, then it must be made by some other group of men or by some one man. The world awaits the solution, men's eyes are turned, looking with expectancy, some hopefully, some fearfully. They long for peace, the peace that will come only when this age-old struggle between Capital and Labor has ceased.

Engineers, even though this message has been heralded throughout the land, are slow to accept the challenge to further serve mankind. They are seemingly content to perform only a part of the work for which they have prepared.

The Federated American Engineering Societies, speaking for the American Engineers, thus defined "Engineering:"

> Engineering is the science of controlling the forces, and of utilizing the materials of nature for the benefit of man, and the art of organizing and directing human activities in connection therewith.
>
> As service to others is the expression of the highest motive to which men respond and as duty to contribute to the public welfare demands the best efforts men put forth—Now, therefore . . . .

If we accept this definition, and as a Society we have already done so, then we cannot escape our duty. The door is open wide. The opportunity for service is before us, a service greater by far than the glorious achievements of the past, an opportunity of weaving together the forces and materials of nature and human efforts into a composite, yet unified and synchronized unit of production, operating with satisfaction to the worker, to the capitalist, and for the benefit of all mankind.

DISCUSSION OF THE POWER WASTE SESSION

(Continued from page 26)

higher steam pressures and temperatures, said that the ideal in station design and operation was the lowest cost of current consistent with reliability. Until the price of coal is much higher, steam pressures will remain practically as at present. The study of the heat balance problem with respect to varying load factor, as emphasized by Mr. Pigott, was important, he said, and in selecting the Colfax system one was chosen which appeared to be the most flexible, most reliable, and to cover the greatest variety of operating conditions. In reply to a statement that control of duplex drive auxiliaries was difficult, he said that this was not so if proper attention were paid to the units. The question of repeating the existing installation, raised by Mr. Scott, was being answered at the Colfax Station by a duplication of the original system of heat balance in a second unit which is now being put in.

C. Harold Berry said that the figures in his paper were for an assumed rather than an actual case, the object being to define the problem, rather than to solve it. It would be interesting, as Mr. Pigott had pointed out, to make such an investigation for varying load factors. The question of duplicating the existing equipment at Conners Creek was answered by the present efforts to change auxiliaries to a direct-current drive for better speed regulation, and the probable installation in the future of economizers.

J. H. Lawrence pointed out the impossibility, in New York, of storing a sufficient quantity of fuel oil for such a station as that at Hell Gate. He had never known of trouble with duplex drive.

In answer to a statement made by Mr. Pope about the danger of overspeeding a turbine at light loads when receiving low-pressure steam in the lower stages, he explained that such connections to turbines in the Hell Gate plant were designed to close with the closing of the main steam valve and prevent over-speeding.

THE ENGINEERING INDEX

(Registered U. S. Patent Office and Canadian Patent Office.)

THE ENGINEERING INDEX presents each month, in conveniently classified form, items descriptive of the articles appearing in the current issues of the world's engineering and scientific press of particular interest to mechanical engineers. At the end of the year the monthly installments are combined along with items dealing with civil, electrical, mining and other branches of engineering, and published in book form, this annual volume having regularly appeared since 1906. In the preparation of the Index by the engineering staff of The American Society of Mechanical Engineers some 1200 technical publications received by the Engineering Societies Library (New York) are regularly reviewed, thus bringing the great resources of that library to the entire engineering profession.

Photostatic copies (white printing on a black background) of any of the articles listed in the Index may be obtained at a price of 25 cents per page, plus postage. A separate print is required for each page of the larger periodicals, but wherever possible two small or medium-sized pages will be photographed together on the same print. The bill will be mailed with the print. When ordering photostats identify the article by quoting from the Index item: (1) Title of article; (2) Name of periodical in which it appeared; (3) Volume, number, and date of publication of periodical; (4) Page numbers. Orders should be sent to the Engineering Societies Library, 29 West 39th Street, New York.

ABRASIVE WHEELS

Selection of. The Proper Selection of Grinding Wheels, P. N. Cooke. Can. Machy., vol. 26, no. 15, Oct. 13, 1921, pp. 25–28. Development and advantages of modern artificial abrasives, grain and grade, manufacturing processes, production grinding; relation of work to grain and grade.

ABRASIVES

Sizing Materials. Sizing of Abrasive Materials, William P. Butler and Paul Keever. Abrasive Industry, vol. 2, no. 10, Oct. 1921, pp. 337–339, 3 figs. Wire sizes and mesh openings of abrasive sizing screens should be standardized to insure classification of uniform grain sizes. (Abstract.) Paper presented before Grinding Wheel Manufacturers' Assn. of U. S. & Canada.

ACCOUNTING

Records for Consulting Engineers. Accounting Records for Consulting Engineers, Arthur L. Mullergren. Eng. News-Rec., vol. 87, no. 17, Oct. 27, 1921, pp. 685–687, 3 figs. Arguments for keeping books with segregated costs. Details of looseleaf system. Forms for expense vouchers and time distribution.

AIR

Specific Heats. The Ratio of the Specific Heats of Air and of Carbon Dioxide, J. R. Partington. Proc. Roy. Soc., vol. 100, no. A702, Oct. 4, 1921, pp. 27–49, 2 figs. Results of experiments on the lines of Lummer and Pringsheim method, eliminating their systematic errors or bringing them under control.

AIR COMPRESSORS

Electrically Driven. Double-Acting Two-Stage Air Compressor. Engineering, vol. 112, no. 2915, Nov. 11, 1921, pp. 674–676, 16 figs. Believed to be largest compressor ever built in Sweden. Driven by directly coupled electric motor, rotor of which is actually mounted on crankshaft. Delivers compressed air to mines.

AIR FURNACES

Firing Method. Equips Air Furnace with Hopper. Iron Trade Rev., vol. 69, no. 17, Oct. 27, 1921, pp. 1082–1084, 4 figs. Coal is dumped into hopper which feeds a specially designed grate as coal is consumed. Only manual labor necessary is that required for pulling the ashes. Method adopted by Allis-Chalmers Mfg. Co.

AIRCRAFT CONSTRUCTION MATERIALS

Fabrics. Permeability of Balloon Fabrics (La Perméabilité des tissus pour ballons), A. D. Ritchie. Révue Universelle des Mines, vol. 10, no. 6, Sept. 15, 1921, pp. 621–631. Discusses rubberized materials and tests made with them.

Spruce. Investigation of Crushing Strength of Spruce at Varying Angles of Grain. Air Service Information Circular, vol. 3, no. 259, July 15, 1921, 15 pp., 10 figs. For determination of crushing or compressive strength from 0 to 90 deg.

AIRPLANE ENGINES

Improvements. Aero Engines, Alan E. L. Chorlton. Jl. Roy. Soc. Arts, vol. 69, no. 3591, Sept. 16, 1921, pp. 725–740, 2 figs. Discusses thermodynamical, mechanical and metallurgical progress made in construction of aeroengines; stratified working, regeneration, bearing loadings and load factors, two-cycle engines, etc.

AIRPLANE PROPELLERS

Theory. The Modern Theory of Aerofoils and Propellers (Die neuere Theorie der Tragflügel und Luftschrauben), E. Everling. Zeit. des Vereines deutscher Ingenieure, vol. 65, no. 44, Oct. 29, 1921, pp. 1142–1143. Investigation of lift and drag based on works by E. Trefftz and R. Fuchs in Zeit. fur angewandte Mathematik u. Mechanik, nos. 3 and 2.

The Prandtl Aerofoil and Propeller Theory (Prandtlsche Tragflächen- und Propeller-Theorie), E. Trefftz. Zeit. fur angewandte Mathematik u. Mechanik, vol. 1, no. 3, June 1921, pp. 206–218, 13 figs. Fundamental principles of theory. Deals with aerofoils which, with given lift, have minimum drag. Calculation of lift and drag of given aerofoils. Screw propellers with minimum loss of energy.

AIRPLANES

Aerofoils. The Minimum Induced Drag of Aerofoils, Max. M. Munk. Nat. Advisory Committee for Aeronautics, Report No. 121, 1921, 18 pp. Mathematical discussion covering, the lifting straight line, parallel lifting elements lying in a transverse plane, three-dimensional parallel lifting elements, lifting elements arranged in any direction in a transverse plane, etc.

De Havilland 32 Biplane. The D.H. 32 Commercial Biplane. Flight, vol. 13, no. 38, Sept. 22, 1921, pp. 629–630, 1 fig. Built by De Havilland Aircraft Co. 360 hp. Rolls-Royce engine.

De Havilland 29 Monoplane. The D.H. 29 Monoplane. Flight, vol. 13, no. 39, Sept. 29, 1921, pp. 641–647, 25 figs. Built at Stag Lane works by De Havilland Aircraft Co. 450 hp. Napier Lion engine. Internally braced wings.

Monoplanes vs. Biplanes. Monoplanes or Biplanes? A. Herbemont. Aviation, vol. 11, no. 15, Oct. 10, 1921, pp. 420–422, 3 figs. Compares several well-known European cabin machines, expressing commercial efficiency as pounds of pay load per horsepower. Translated from L'Air.

Pilotless. Pilotless Airplanes (L'avion sans pilote), A. Volmerange. Aeronautique, vol. 3, no. 28, Sept. 1921, pp. 345–351, 5 figs. Discusses automatic stability, the Sperry stabilizer, principle of distance-control, starting and landing.

[See also PARACHUTES.]

AIRSHIPS

Rubberized Fabric. Balloons, Airships and Rubberized Fabric, C. P. Burgess. India Rubber World, Vol. 65, no. 1, Oct. 1, 1921, pp. 3–6, 6 figs. Discusses principal characteristics of some typical airships and balloons, achievements of rubberized fabrics, etc.

Zeppelin. The Drag of Zeppelin Airships, Max M. Munk. Nat. Advisory Committee for Aeronautics, Report No. 117, 1921, 11 pp., 10 figs. Results of tests in which the propellers were stopped as quickly as possible while airship was in full flight.

ALLOY STEELS

Carbon and. Carbon and Alloy Steels: Their Selection and Use, P. W. Peel. Practical Engr., vol. 61, no. 1803, Sept. 15, 1921, p. 167.

Hardening. The Hardening of Tool Steel, S. N. Brayshaw. Eng. Production, vol. 3, no. 57, Nov. 3, 1921, p. 415. Results of work carried out by means of test bars and test cutters for purpose of determining effect of various annealings or heat treatments. (Abstract). Paper read before Sheffield Assn. Metallurgists & Metallurgical Chemists.

High-Resistance. Non-Magnetic, Flame-, Acid- and Rust-Resisting Steel. Chem. & Met. Eng., vol. 25, no. 17, Oct. 26, 1921, pp. 797–799, 5 figs. New high alloy steels developed in research laboratory of Crucible Steel Co. which can easily be worked and machined, but after heat-treatment become hard and resistant to attack of all agencies.

Tests. Elasticity and Strength of Special Steels at High Temperatures (Elastizitat und Festigkeit von Spezialstahlen bei hohen Temperaturen), Georg Welter. Forschungsarbeiten auf dem Gebiete des Ingenieurwesens, no. 230, 1921, 65 pp., 99 figs. Results of tests carried out on special steels such as are commonly used in construction of steam turbines and engines, and gas, oil, automobile and airplane engines, to determine limit of elasticity at which permanent dilatation of steel begins. Describes apparatus used for tests.

ALLOYS

See BEARING METALS; COPPER ALLOYS; NICKEL ALLOYS; ZINC ALLOYS.

ALUMINUM

Annealing, Effect of. Unusual Grain Growth Due to Critical Strain, A. P. Knight. Chem. & Met. Eng., vol. 25, no. 18, Nov. 2, 1921, pp. 829–830, 7 figs. Discusses annealing of aluminum coffee pots, bottom of which was rough while sides were smooth.

Properties and Alloys. Aluminum, Its Production, Properties and Alloys (L'Aluminium, sa fabrication, ses proprietes, ses alliages), Léon Guillet. Révue de Metallurgie, vol. 18, no. 8, August 1921, pp. 461–526, 70 figs. Report of lecture at recent aluminum exposition. Appendixes giving curves for binary alloys. Bibliography.

ALUMINUM ALLOYS

Automobile Construction. Use of Wrought Aluminum Alloys in Automobile Construction, Walter Rosenhain. Automotive Industries, vol. 45, no. 18, Nov. 3, 1921, pp. 862–864. Discusses advantages and possible applications, piston difficulties, corrosion.

Bronzes. Notes on Casting Aluminum Bronze, Austin D. Wilson. Foundry, vol. 49, no. 20, Oct. 15, 1921, pp. 801–804, 27 figs. Micrographs illustrate effects of different compositions and heat treatments on structure. Presence of manganese tends to refine grain.

Castings, Cracks in. Cracks in Aluminum-alloy Castings, Robert J. Anderson. Trans. Am. Inst. Min. & Metallurgical Engrs., no. 1101-N, Oct. 1921, 22 pp.; also (in abstract), Min. & Metallurgy, no. 178, Oct. 1921, pp. 43–44. Effects of various factors on cracking; method of molding; prevention of cracks.

ANEMOMETERS

Testing. Measurement of Air Velocities and the Testing of Anemometers, James Cooper. Iron & Coal Trades Rev., vol. 103, no. 2798, Oct. 14, 1921, p. 540. Discusses results obtained with a testing anemometer table based on that designed by H. Briggs many years ago and which is claimed to work perfectly.

ASH HANDLING

Conveyor. A New Ash Handling Conveyor. Eng. & Indus. Management, vol. 6, no. 16, Oct. 20, 1921, pp. 449–450, 4 figs. Describes system developed by Underfeed Stoker Co., Ltd., London.

AUTOMOBILE ENGINES

Cylinders. How Ford Cylinder Blocks are Cast, Pat Dwyer. Foundry, vol. 49, no. 19, Oct. 1, 1921, pp. 751–758, 7 figs. New River Rouge plant operated on continuous production principle; to make castings for 8,000 cars per day. Description of making cores, molds, pouring castings, melting equipment, etc.

Eight-Cylinder. Engines with Eight Cylinders in Line (Le Moteur a huit cylindres en ligne), A. Contet. La Vie Automobile, vol. 17, no. 738, Sept. 25, 1921, pp. 335–339, 12 figs. Discusses variations of eight-cylinder crankshafts and describes Panhard, Fraschini and other eight-cylinder engines.

Light-Metal. Recent Experiences with Light Metals in High-Speed Engines (Neue Erfahrungen mit Leichtmetallen in schnellaufenden Motoren), H. v. Selve. Zeit. für Metallkunde, vol. 13, no. 10, July 1921, pp. 316–318, 7 figs. Based on tests and experiences, writer strongly recommends increased use of aluminum and magnesium alloys in automobile construction and gives comparative data on weight, strength and expansion of aluminum castings and aluminum sheet pistons and magnesium pistons, as well as of connecting rods of steel and magnesium.

Rotary-Valve. A New Rotary Valve Engine. Automotive Industries, vol. 45, no. 22, Dec. 1, 1921, pp. 1065–1066, 3 figs. Chief advantage claimed is that of absolutely silent operation. Absence of valves and tappet rods at side of cylinder block allows location of accessories close to cylinders and a consequent narrow engine.

[See also CARBURETORS; CLUTCHES; CRANKCASES.]

AUTOMOBILE FUELS

Coke. Coke As a Fuel for Commercial Vehicles, Thomas Clarkson. Engineering, vol. 112, no. 2912, Oct. 21, 1921, pp. 579–580. Points out that when coke is used as motor fuel, either for raising steam or making gas, cost of transport may be very considerably reduced as compared with gasoline motor. Paper read before Instn. Automobile Engrs.

Condensation Temperatures. Condensation Temperatures of Gasoline- and Kerosene-Air Mixtures, Robert E. Wilson and D. P. Barnard. Jl. Indus. & Eng. Chem., vol. 13, no. 10, Oct. 1921, pp. 906–912, 12 figs. Describes a simple and reliable method for determining initial condensation temperature of fuels from air-fuel mixtures, an approximate method for determining temperatures of partial condensation in air-fuel mixtures, etc.

Kerosene. The Use of Kerosene in Automobile Engines (L'Emploi des pétroles lampants dans les moteurs d'automobiles), A. Grebel. Memoirs et Compte Rendu des Travaux de la Société des Ingenieurs Civils de France, vol. 74, no. 4-5-6, April-June 1921, pp. 250–269. Holds that it is not so much a question of carburization and carburetors, but of the engines, cycles, and manner of regulation. Tables of liquid fuels and their properties.

Total Heat Content. The Total Sensible Heats of Motor Fuels and Their Mixtures with Air, Robert E. Wilson and D. P. Barnard. Jl. Indus. & Eng. Chem., vol. 13, no. 10, Oct. 1921, pp. 912–915, 5 figs. Describes approximate methods in determining the total sensible heat content of Socony motor gasoline and kerosene and their mixtures with air at temperatures up to 500 deg. cent.

AUTOMOBILES

Camshafts. Manufacture of Accurate Camshafts, Edward K. Hammond. Machy. (N. Y.), vol. 28, no. 3, Nov. 1921, pp. 175–180, 8 figs. partly on p. 181. Describes important operations, and gives complete tabulated data on manufacturing procedure in making camshafts in Lincoln Motor Co.'s plant.

Declutcher, Automatic. Automatic Declutcher Introduced at Paris Show. Automotive Industries, vol 45, no 19, Nov. 10, 1921, p. 922, 3 figs. Gear shifting accomplished by taking foot off accelerator pedal and waiting until engine slows down to point where it is sure to be uncoupled by new device. Gear lever is then shifted without disengaging friction clutch.

Delage. A New 11 Hp. Delage. Autocar, vol. 47, no. 1353, Sept 21, 1921, pp. 533–535, 7 figs. Four cylinder monobloc, 72 × 130 mm.; electric lighting and starting, four-speed gear; four-wheel braking system.

Duesenberg. New Duesenberg Reflects Experience Gained with Racing Cars, J. Edward Schipper. Automotive Industries, vol 45, no. 18, Nov. 3, 1921, pp. 854–857, 5 figs Equipped with eight-in-line engine, four-wheel brakes, overhead camshaft, and tubular connecting rods, high pressure oiling, semi-elliptical springs.

Electric, Suspension. Eliminating Vibrations and Shocks in Electric Motor Vehicles (Come eliminare i danni delle vibrazioni e degli urti nei veicoli automotori elettrici), Gino Turrinelli. L'Elettrotecnica, vol. 8, no. 26, Sept. 25, 1921, pp 581–584, 11 figs. Discusses methods of suspension and describes new system of suspension.

Fiat. The 10 Hp. Fiat (La 10 Hp. Fiat), A. Contet. La Vie Automobile, vol. 17, no. 737, Sept. 10, 1921, pp. 307–311, 15 figs. Discusses chassis, engines (four- and six-cylinder monobloc), speed control, etc.

Gear Release. Automatic Gear-Release (L'Auto-débrayage T. L.), G. Lienhard. La Vie Automobile, vol. 17, no. 738, Sept. 25, 1921, pp. 354–358, 12 figs. Describes the T. L. device, consisting of a wheel with a helicoidal rim, similar to the free wheel of bicyles, placed between engine and transmission gear.

German. New German Car Has Novel Design Features, Benno R. Dierfeld. Automotive Industries, vol. 45, no. 15, Oct. 13, 1921, pp. 703–706, 5 figs. Clutch design of this 30-hp. Protos is entirely new; unusual method of locking gears in position; cylinder block is excellent example of German engineering and foundry practice; no control hand levers on steering wheel; four-cylinder engine used.

Haynes. Longer Wheelbase and Larger Engine in New Haynes, J. Edward Schipper. Automotive Industries, vol. 45, no. 16, Oct. 20, 1921, pp. 764–766, 6 figs. New model "75" has 132-in. wheelbase and 299-cu. in. engine with block-cast cylinders, inclined valves, chain distribution, three-piece separate head, aluminum crankcase and hollow-shaft lubrication.

Improvements. Improvements in Automobile Manufacture (Neue Wege im Automobilbau), Otto Schwager. Motorwagen, vol. 24, nos. 26 and 27, Sept. 20 and 30, 1921, pp. 565–566 and 579–591, 15 figs. New Rumpler car with drop-pearl-shaped (streamline) frame and body based on experiences in airplane construction. The gearless Maybach car. The Atlantic two-seated cycle car.

Mack A B Chassis. Mack Chassis Now Adapted for Use as Rail Cars, Herbert Chase. Automotive Industries, vol. 45, no. 19, Nov. 10, 1921, pp. 918–921, 6 figs. Vehicles used for railway work have special axles, wheels and reverse gears, but most other parts of the chassis are identical with those used in standard Mack trucks. Special bodies seat from 25 to 35 passengers.

Pierce-Arrow Repair Service. Automotive Service Methods and Equipment Howard Campbell. Am. Mach., vol. 55, no. 20, Nov. 17, 1921, pp. 789–791, 7 figs. Tools used in remachining Pierce-Arrow transportation units. Reboring fixtures. Valve-spring tester. Welding and remilling axle shafts.

Renault 40-Hp. Testing a 40-Hp. Renault Automobile (Essai d'une Voiture Renault 40 chevaux), H. Petit. La Vie Automobile, vol. 17, no. 738, Sept. 25, 1921, pp. 340–346, 16 figs. Test data and description of engine (6-cylinder), transmission gear, chassis, etc.

Rumpler. A German Passenger Car of Radical Design. Automotive Industries, vol. 45, no. 17, Oct. 27, 1921, pp. 812–816, 12 figs. Describes Rumpler streamline car. Engine is aft and every possible obstacle on streamline body is removed to minimize air resistance.

Rumpler's New Automobile (Der neue Kraftwagen von Dr. Ing. Rumpler), A. Heller. Zeit. des Vereines deutscher Ingenieure, vol. 65, no. 39, Sept. 24, 1921, pp. 1011–1015, 11 figs. Special feature is its rear-axle drive with which only the compensating shafts oscillate and all joints are eliminated. Due to location of entire drive in rear a favorable form could be developed with regard to air resistance.

Stevens-Duryea Stevens-Duryea Producing High Grade Six, Herbert Chase. Automotive Industries, vol. 45, no. 22, Dec. 1, 1921, pp. 1061–1064, 7 figs. Describes changes made in chassis and Model E power plant, and gives details of construction.

Sunbeam 4-Seater. A New 2-Litre Sunbeam. Autocar, vol. 47, no. 1355, Oct. 8, 1921, pp. 624–627, 13 figs. Four-seater, 14-hp., four-cylinder 72 × 120 mm., overhead valves, aluminum cylinder blocks.

Suspension. The Suspension of Vehicles (Remarques sur la suspension des véhicules), P. Lemaire. La Technique Moderne, vol. 13, no. 1, Jan. 1921, pp. 7–11, 2 figs. Discusses transmission of shocks by wheels, comfortable and uncomfortable speeds, elastic constants of springs.

See also Electric, Suspension.

Wills Sainte Claire. Wills Sainte Claire Car Has Engine of Original Design, J. Edward Schipper. Automotive Industries, vol. 45, no. 19, Nov. 10, 1921, pp. 912–917, 8 figs. Eight-cylinder solid-head engine, overhead camshaft drive. Describes cooling system, oil circuit, etc. Gives specifications. 65 b.hp. at 2700 r p.m. maximum.

Wolseley 7-Hp. A New 7-Hp. Wolseley. Autocar, vol. 47, no. 1353, Sept. 24, 1921, pp. 541–543, 9 figs. Water-cooled horizontally opposed twin, 82 × 92 mm. three-speed and reverse gear.

AVIATION

Air Harbors. Canadian Airharbors. Aviation, vol. 11, nos. 16 and 17, Oct. 17 and 24, 1921, pp. 448–450 and 481–482, 1 fig. Detailed description of each; markings for air harbors; the part of Canadian Air Regulations which provides for licensing of air harbors.

B

BALLOONS

Captive, Winding Machinery for. Winches for Captive Balloons (Les treuils de ballon captif), Léon Chollet. L'Aeronautique, vol. 3, nos. 27 and 28, August and Sept. 1921, pp. 316–319 and 377–380, 6 figs. Aug.: Describes various cars or trucks driven by steam or gasoline. Sept.: Discusses power of engine, speed of bringing down the balloon, winding cable, etc.

BEAMS

Continuous. Calculations for Continuous Beams with Third-Point Loading, Ewart S. Andrews. Concrete & Constructional Eng., vol. 16, no. 10, Oct. 1921, pp. 647–654, 5 figs. Deals with beams continuous over three spans.

Maximum Bending-moment Diagrams for Continuous Beams, C. S. Gray. Mech. World, vol. 70, no. 1813, Sept. 30, 1921, pp. 266–267, 7 figs. Discusses Clapeyron's theorem of three moments.

Curved. Bending Lines of Curved Beams (Biegungslinien ringförmiger Träger), Friedrich Düsterbehn. Eisenbau, vol. 12, no. 10, Oct. 11, 1921, pp. 249–264, 7 figs. Bending lines are developed for deformation of curved beams.

Sections. The Graphics of Beam and Girder Sections. Alan Pollard. Machinery (Lond.), vol. 19, no. 473, Oct. 20, 1921, pp. 63–66, 4 figs. Method for determining the centroid, moment of inertia, swing radius, and moduli for any shape of section on drawing board.

BEARING METALS

Properties. What Metals Serve Best in Bearings? Bruno Simmersbach. Raw Material, vol. 4, no. 9, Sept. 1921, pp. 316–320. Relation between physical-chemical properties of bearing alloys and their ability to live under strenuous duty. From Chemiker Zeitung.

BEARINGS, BALL

Roller and. Anti-Friction Bearings in the Steel Mill, A. M. MacCutcheon. Blast Furnace & Steel Plant, vol. 9, no. 10, Oct. 1921, pp. 600–607, 13 figs. Discusses ball and roller bearings, their manufacture, mounting and selection. Advantages and disadvantages of anti-friction bearings. (Abstract.) Paper read before Iron & Steel Elec. Engrs.

BEARINGS, ROLLER

Tangential Load. Experiments with Roller Bearings Under Tangential Load (Undersökningar rörande rullning under tangentialkraft), Arvid Palmgren. Teknisk Tidskrift (Mekanik), vol. 51, no. 9, Sept. 14, 1921, pp. 129–132, 8 figs. Discusses results of tests made in the S. K. F. laboratory.

BELTING

Cellulose. Tests with Cellulose Driving Belts (Versuche mit Zellstofftreibriemen), H. Rudeloff. Zeit. des Vereines deutscher Ingenieure, vol. 65, no. 40, Oct. 1, 1921, pp. 1041–1044, 4 figs. Account of tests to determine strength of paper composed of equal parts of soda and sulphite cellulose in the different stages of manufacture, for purpose of ascertaining degree to which strength of cellulose employed in yarns, textures and belts is utilized.

Rubber. Getting the Maximum Service in Rubber Transmission Belting, James B. McPherson. Chem. & Eng. News, vol. 33, no. 10, Oct. 1921, pp. 29–30. Writer advises securing maximum coefficient of friction, maximum arc of contact practicable, avoiding excessive tension, reckless use of dressings, and careless fastenings.

BLAST-FURNACE GAS

Steam Power from. Steam Power from Blast-Furnace Gas, Gordon Fox and F. H. Willcox. Power, vol. 54, no. 20, Nov. 15, 1921, pp. 706–709, 3 figs. Résumé on utilization of blast-furnace gas for steam making and development in burning gas alone or in combination with other fuels. Typical data are given as to amount of gas available and variation in supply. Importance of cleaning gas is emphasized, numerous recent installations are cited and developments in design summarized.

BLAST FURNACES

High Top Heat. Causes of High Top Heat in the Blast Furnace, Wallace G. Imhoff. Chem. & Met. Eng., vol. 25, no. 16, Oct. 19, 1921, pp. 737–740. Charts recording temperature of waste gases are of value in controlling furnace operations, indicating especially clearly exact time when charging is done and if charge is alternately hanging and slipping.

Pennsylvania. New Blast Furnace of the Crane Iron Works Modernizes Plant at Catasauqua, Pa., Richard Peters, Jr. Blast Furnace & Steel Plant, vol. 9, no. 10, Oct. 1921, pp. 577–580, 4 figs. Details of improvements in new blast furnace.

600-Ton. New 600-Ton Blast Furnace Plant. Blast Furnace & Steel Plant, vol. 9, no. 10, Oct. 1921, pp. 588–597, 11 figs. Trumbull Cliffs Furnace Company new plant at Warren, Ohio, now completed. Many interesting features constructed in this plant. Record time made on construction work.

BLOWERS

Propeller Type. Propeller Blowers for Forced-Draft Furnaces (Propellergebläse für Unterwindfeuerungen), Werner Muller. Zeit. für Dampfkessel u. Maschinenbetrieb, vol. 44, no. 36, Sept. 9, 1921, pp. 281–284, 12 figs. Details of the Föge propeller blower based on design of airplane propellers. Discusses shape of propeller and housing, speed, power consumption and efficiency. Installation in forced-draft furnaces.

BOILER FEEDWATER

Concentration, Control of. Priming and Control of Boiler Water Concentration, Geo. C. Cook. Power Plant Eng., vol. 25, no. 20, Oct. 15, 1921, pp. 986–988. Discusses limit of impurities in feedwater and methods of controlling degree of concentration.

BOILER FIRING

Fuel Saving in. Fuel Saving in Relation to Capital Necessary, Joseph Harrington. Mech. Eng., vol. 43,

no. 11, Nov. 1921, pp. 723–726, 2 figs. Investigation shows economy resulting from use of efficiency equipment. Concrete illustrations given in support of theory discussed. (Abstract.)

Refined Fuel. Practical Experiences in Boiler Firing with Refined Fuels (Praktische Erfahrungen im Dampfkesselbetrieb mit veredelten Brennstoffen), H. Morgner. Zeit. für Dampfkessel u. Maschinenbetrieb, vol. 44, no. 33, Aug. 19, 1921, pp. 257–259. Notes on use of pulverized coal, and mixtures of anthracite and lignite.

BOILER PLANTS

Efficient Operation. Boiler-Plant Efficiency, Victor J. Azbe. Mech. Eng., vol. 43, no. 11, Nov. 1921, pp. 722–724 and 726, 5 figs. Usual wastes in boiler plants are brought out by means of tables and curves of boiler performance compiled from large number of observations. Shows to what extent these wastes are preventable or can be made to balance each other, and recommends standard for boiler operation toward which designers and operators may aim. Requirements of ideal boiler installation are summarized.

Oil-Burning. High-Pressure Oil-Burning Installation. Power, vol. 54, no. 17, Oct. 25, 1921, pp. 623–624, 5 figs. Boiler plant of Fall River Electric Light Co. converted from coal to oil burning.

Wimbledon Electrical Works. The New Boiler House Plant at Wimbledon Electricity Works. Eng. & Indus. Management, vol. 6, no. 15, Oct. 13, 1921, pp. 402–403, 1 fig. Consists of two Spearing horizontal water-tube boilers, each having actual evaporative capacity of 25,000 lb. per hr. with overload capacity for 8 hr. of 25 per cent above full load. Details of drive and feed pump.

BOILERS

Design and Settings. Boiler Equipment at River Rouge Plant of the Ford Motor Company, George T. Ladd. Proc. Engineers' Soc. of Western Pa., vol. 37, no. 3, April 1921, pp. 115–148 and (discussion) 149–157, 17 figs. Discusses design of boilers and settings. Discussion of powdered coal equipment and superheater equipment by H. D. Savage and J. R. Le Vally, respectively.

Flanging Methods. Special Methods of Boiler Flanging, George A. Richardson. Boiler Maker, vol. 21, no. 10, Oct. 1921, pp. 281–283, 8 figs. Hand flanging and sectional presses used for irregular shapes in boiler and tank fabrication.

BOILERS, WATER-TUBE

Advantages. The Advantages of Water Tube Boilers, James Kemnal. Mar. Eng. of Can., vol. 11, no. 9, Sept. 1921, pp. 22–23. Describes various cases where cylindrical boilers were replaced by water tube boilers.

BONUS SYSTEMS

Practical Application. Practical Application of the Bonus System for Increased Production (Della practica applicazione del sistema del premio di maggior produzione nelle officine del materiale fisso di Pontassieve), Giorgio Lasz. Rivista Tecnica delle Ferrovie Italiane, vol. 22, no. 2, Aug. 15, 1921, pp. 66–70. Describes experience with Rowan piece work system at an Italian railroad shop.

BRAKES

Air, Westinghouse. New Tests of the Westinghouse Continuous Air Brake (Nouveaux essais du frein continu système "Westinghouse"), M. Tête. Revue Générale des Chemins de Fer et des Tramways, vol. 40, no. 7, July 1921, pp. 22–50, 8 figs. Results of tests in France by commission appointed by Minister of Public Works are entirely satisfactory.

Automotive Engine. Motor Brakes (Motorbremsen), C. Wirsum. Motorwagen, vol. 24, no. 27, Sept. 30, 1921, pp. 600–605, 12 figs. Investigations of the braking effect of automotive engines and recommendations for design. Results of tests with Saurer brakes.

BRASS FOUNDRIES

Cast Ingots. The Casting of Brass Ingots, R. Genders. Metal Industry (Lond.), vol. 19, no. 14, Sept. 30, 1921, pp. 261–262, 2 figs. Describes experiments carried out to minimize occurrence of non-metallic inclusioos.

BRONZES

Antimony, Influence of. The Influence of Antimony in Bronze (Der Einfluss des Antimons im Rotguss), J. Czochralski. Zeit. für Metallkunde, vol. 13, no. 9, June 1921, pp. 276–281, 8 figs. Investigation of influence of antimony additions up to 3 per cent on mechanical properties of bronze with and without lead. It is shown that with antimony content up to 0.3 per cent with 5 per cent lead content the treatment and casting of bronze is favorably influenced.

Arsenic, Influence of. The Influence of Arsenic in Bronze (Der Einfluss des Arsens im Rotguss), J. Czochralski. Zeit. für Metallkunde, vol. 13, no. 11, Aug. 1921, pp. 380–383, 10 figs. Investigation of influence of additions of up to 2 per cent of arsenic on mechanical properties of bronze with and without lead. It is shown that with arsenic content of up to 3 per cent with 5 per cent lead content the casting of bronze is favorably influenced.

Cold-Drawing, Effect of. The Effect of Progressive Cold-Drawing Upon Some of the Physical Properties of Low-Tin Bronze, W. E. Alkins and W. Cartwright. Metal Industry (Lond.), vol. 19, no. 15, Oct. 7, 1921, pp. 280–285 and (discussion) p. 286, 7 figs. Gives results of experiments showing variation during cold-drawing of the three properties: tensile strength, specific volume and scleroscope hardness. Describes characteristics of individual curves. Paper read before Inst. of Metals.

C

CABLES, HOISTING

Metal. Metal Cables For Winding Engines (Les cables d'extraction metalliques ronds), M. Durnerin. Revue de l'Industrie Minérale, no. 18, Sept. 15, 1921, pp. 579–599, 5 figs. Discusses construction, choice of steels, effect of torsion, elasticity of cables and its parts, calculation of cross-sections, and describes a patented automatic "anti-torsion" which increases life of cable.

CAR LIGHTING

Gas and Electric. Railway Car Lighting, George E. Hulse. Trans. Illuminating Eng. Soc., vol. 16, no. 5, July 20, 1921, pp. 99–110 and (discussion) 110–116. Discusses gas and electric lighting, reflectors, and glassware.

CAR SHOPS

Equipment. Kanchrapara Carriage and Wagon Works, Eastern Bengal Railway. Ry. Gaz., vol. 35, no. 17, Oct. 21, 1921, pp. 598–600, 12 figs., partly on pp. 601–604. A scientifically designed layout, together with up-to-date machine, etc., equipment, combine to make Kanchrapara works of special interest.

CARS

Couplers. Measures for the Solution of the Coupling Problem for Main and Narrow-Gage Lines (Massnahmen zur Lösung der Kupplungsfrage für Haupt- und Kleinbahnen), H. Scharfenberg. Glasers Annalen, vol. 89, nos. 3 and 4, Aug. 1 and 15, 1921, pp. 27–32 and 37–42 and (discussion) pp. 42–44, 19 figs. Discusses development and different coupling systems. Address before German Mech. Eng. Soc.

Dining. Great Northern Train Service Between London and West Riding of Yorkshire. Ry. Gaz., vol. 35, no. 17, Oct. 21, 1921, pp. 607–610, 9 figs., partly on pp. 605–606. Describes new rolling stock built on twin bogie principle, with an articulated dining car train, embodying various improvements, including electric cooking.

Pressed Metal Parts. The Use of Pressed Parts in Car and Locomotive Construction (Die Verwendung von Pressteilen im Waggon- und Lokomntivbau), W. Loewe. Glasers Annalen, vol. 89, no. 3, Aug. 1, 1921, pp. 32–36, 12 figs. Describes production of pressed metal parts and suggests means of overcoming difficulties in connection with their adoption. Among their advantages over cast parts are mentioned, greater safety, elimination of use of copper, and adaptability to standardization.

CARS, PASSENGER

Design. On the Question of Passenger Carriages, E. Biard. Bulletin International Ry. Assn., vol. 3, no. 9, Sept. 1921, pp. 1205–1274. Discusses safety and comfort, types of construction and general design of carriages, component parts, chief devices and various accessories of underframe and body. Appendixes.

CARS, REFRIGERATOR

Milk Tanks, Use of. The Use of Car Tanks for Transporting Milk. Ry. Rev., vol. 79, no. 17, Oct. 22, 1921, pp. 543–514, 2 figs. Describes equipment of B. & O. R.R. for transporting milk in bulk in refrigerator cars fitted with glass-lined tanks.

CARBURETORS

Kerosene. Carburetors for Kerosene (Les Carburateurs a Pétrole), A. Mariage. Memoirs et Compte Rendu des Travaux de la Société des Ingenieurs Civils de France, vol. 74, no. 4–5–6, April-June 1921, pp. 279–290, 3 figs. Expresses the views of Compagnie Générale des Omnibus of Paris and gives results of their experiments.

CASTING

Centrifugal. Control of Centrifugal Casting by Calculation, Robert F. Wood. Mech. Eng., vol. 43, no. 11, Nov. 1921, pp. 727–728 and 730, 2 figs. Analyzes controlling factors, with view first of setting down definite mathematical relations between them, and secondly so expressing these relations as to make them useful both in design and operation of machines for casting. (Abstract.)

Melts Metal For Pipe in the Mold, E. C. Kreutzberg. Foundry, vol. 49, no. 19, Oct. 1, 1921, pp. 772–774, 6 figs. Centrifugal casting process developed by L. Cammen uses an electrically heated mold. Aluminum tubing made by this process which will be developed for casting steel.

CASTINGS

Molds, Plaster. Permanent Molds, Edward D. Gleason. Metal Industry (N. Y.), vol. 19, no. 10, Oct. 1921, pp. 391–393. Description of methods of making plaster molds for finished castings to eliminate machining operations.

Non-Ferrous. Producing Small Nonferrous Castings, Raymond H. Sullivan. Can. Foundryman, vol. 12, no. 10, Oct. 1921, pp. 30–32, 2 figs. Discusses daily production of a large number of small duplicate castings and method adopted. Paper read at Foundrymen's Convention.

CENTRAL STATIONS

Blackburn, England. New Electricity Generating Station at Blackburn. Engineer, vol. 132, no. 3434, Oct. 21, 1921, pp. 416–420, 8 figs. Station contains two turbo-alternators, each of 10,000 kw. capacity. Details of coal- and ash-handling plant; boiler plant; cooling towers; switchgear, transformers, etc.

Cotton Industry. Value of Central Station Service in the Cotton Industry, F. E. Sawyer and H. E. Duren. Nat. Elec. Light Assn. Bul., vol. 8, no. 10, Oct. 1921, pp. 586–590. Describes some mills that have changed from own power production to purchased power and its advantages.

CHAIN DRIVE

Silent. The Application and Manufacture of Silent Chain, J. Edward Schipper. Automotive Industries, vol. 45, no. 16, Oct. 20, 1921, pp. 773–778, 18 figs. Manufacture of chain parts, their assembly and inspection, is outlined.

CHROMIUM STEEL

Bibliography. A Bibliography and Abstract of Chromium Steels, F. P. Zimmerli. Chem. & Met. Eng., vol. 25, no. 18, Nov. 2, 1921, pp. 837–843. Chronological arrangement of some of the principal papers on chromium and chromium alloy steels published during the period 1798 to 1919, with brief summary of their scope.

CLUTCHES

Manufacture and Assembly. The Manufacture and Assembly of a Cork Insert Disk Clutch, J. Edward Schipper. Automotive Industries, vol. 45, no. 17, Oct. 27, 1921, pp. 823–826, 13 figs. Description of machining and assembly operations on Hudson and Essex clutches.

COAL HANDLING

Screening and Loading Installation. Screening and Loading Installation of the Bockit-Asem Anthracite Mine at Tandjoeng in Sumatra (Kolenzeefen laadinrichting voor de Bockit-Asem-steenkolenmignen te Tandjoeng op Sumatra), A. Guyot Van Der Ham. Ingenieur, vol. 36, no. 39, Sept. 24, 1921, pp. 772–774, 3 figs. Constructed by Baum Machine Works, Herne, Westfalia. Details of arrangement and equipment.

COKE

Uses. Production, Distribution, and Uses of Coke, E. W. L. Nicol. Gas Jl., vol. 156, no. 3047, Oct. 5, 1921, pp. 37–38. Discusses use of coke as fuel and adapting boiler furnaces to coke. See also Iron & Coal Trades Rev., vol. 103, no. 2796, Sept. 30, 1921, p. 471.

COMBUSTION

Equations. Combustion Equations (Die Gleichungen des Verbrennungsvorganges), R. Mollier. Zeit. des Vereines deutscher Ingenieure, vol. 65, no. 42, Oct. 15, 1921, pp. 1095–1096. The stoichiometrical ratios for incomplete combustion are developed.

High-Pressure. Gaseous Combustion at High Pressures—II, William Arthur Bone and William Arthur Haward. Proc. Roy. Soc., vol. 100, no. A 702, Oct. 4, 1921, pp. 67–84, 7 figs. Further experiments to determine a direct relation between the actual rate at which potential energy is transferred on explosion as sensible heat to its products and the magnitude of chemical affinity between its combining constituents.

Initial Temperatures. Initial Temperatures with Heated Combustion Air (Ueber Anfangstemperaturen mit erhitzter Verbrennungsluft), Otto H. Binder. Feuerungstechnik, vol. 9, no. 23, Sept. 1, 1921, pp. 219–220, 1 fig. Presents formula used by author for calculation of initial temperatures.

CONDENSERS, STEAM

New Type High-Efficiency. Steam-Condensing Plants, Paul A. Bancel. Mech. Eng., vol. 43, no. 11, Nov. 1921, pp. 711–716 and 758, 14 figs. Detailed consideration of fixed and operating charges in surface-condenser installations, and description of new type of high-efficiency condenser.

CONVEYORS

Pulverized Materials. Pulverized-Material Conveyor System. Power, vol. 54, no. 17, Oct. 25, 1921, pp. 628–629, 4 figs. Describes the Fuller-Kinyon conveying system for pulverized material, comprising a power-driven pump, function of which is to start the mass in motion; source of compressed-air supply and a pipe through which material flows.

Types. Mechanical Handling and Conveying of Materials, Richard P. Terry. Mech. World, vol. 70, nos. 1814 and 1815, Oct. 7 and 14, 1921, pp. 293–294 and 301–302. Oct. 7: Discusses bucket elevators and worm or Archimedean screw conveyors. Oct. 14: Discusses band, Zimmer, gravity and pneumatic conveyors. Paper read before Belfast Assn. of Engrs.

[See also ASH HANDLING, Conveyor.]

COOLING TOWERS

Investigation. Investigation of Chimney Cooling Towers (Die Beurteilung von Kaminkühlern), Kurt Neumann. Zeit. des Vereines deutscher Ingenieure, vol. 65, no. 41, Oct. 8, 1921, pp. 1070–1074, 3 figs. Thermodynamic investigation of phenomena occurring in chimney cooling towers. Equation is derived for determination of temperatures of the hot and recooled water dependent upon operating conditions. Gives results of tests on high-capacity cooling towers in industrial operation.

COPPER ALLOYS

Cupro-Nickel. Manufacture of Cupro-Nickel, Herbert D. Swift. Metal Industry (N. Y.), vol. 19, no. 10, Oct. 1921, pp. 394–395. Description of process going in regular order from casting to packing.

CORROSION

Electrolytic. Electrolytic Corrosion of Lead Thallium Alloys, Colin G. Fink and Charles H. Eldridge. Am. Electrochem. Soc., advance paper, no. 26, for meeting Sept. 29-Oct. 1, 1921, pp. 335–344, 4 figs. Shows that addition of thallium to lead alloys has been very effective in reducing anodic corrosion in acid copper sulphate electrolyte containing nitric and hydrochloric acids.

Heating System. Preventing Corrosion in Heating Systems, Perry West. Domestic Eng. (Chicago), vol. 97, no. 2, Oct. 8, 1921, pp 50 53 and 82-84, 4 figs. Describes deoxidizing and de-aerating methods.

COST ACCOUNTING

Classification of Surplus. Classification of Surplus, C. B. Couchman Jl of Accountancy, vol. 32, no. 4, Oct. 1921, pp. 265-278 Discusses various kinds of surpluses and their display in the accounts. Paper read before Am. Inst of Accounts

Uniform Mill Systems. Uniform Mill Cost Systems, C. Oliver Wellington. Paper, vol. 29, no. 6, Oct. 12, 1921, pp. 13-15. Discusses advantages of uniformity in cost accounting.

COSTS

Material, Recording. The Recording of Material Costs, E W. Workman. Eng. & Indus. Management, vol. 6, no. 16, Oct. 20, 1921, pp. 426-427. Describes method of dealing with material charges which has been found to work exceptionally well in large engineering firm using Hollerith system for dealing with its labor and overhead expenses.

CRANES

Bridge. New Type of Bridge Crane for Handling Sand and Gravel, W. A. Scott. Cem., Mill & Quarry, vol. 19, no 8, Oct 20, 1921, pp. 27-28, 2 figs. Has max. length of 184 ft.; clamshell bucket has capacity of 3 yd; carriage speed, 800 ft. per min.; bucket speed, 200 ft.

Locomotive. Crane Operated on a Railroad Truck (Grue pivotante sur wagon a voie normale). Bulletin Technique de la Suisse Romande, vol. 47, no. 20, Oct. 1, 1921, pp. 229-234, 3 figs. Carrying capacity of cranes 10-12 tons, radius of action 6 m. Trucks are of special construction.

CRANKCASES

Malleable-Iron. Crank Cases Made of Malleable Iron. Foundry, vol. 49, no. 19, Oct. 1, 1921, pp. 762-766, 10 figs. An extensive series of experiments in molding and in subsequent heat treatment was required before castings were produced on a commercial basis.

CUTTING METALS

Universal Oxygen-Jet. A Universal Oxygen-Jet Cutting Machine. Eng. Production, vol. 3, no. 56, Oct. 27, 1921, pp. 395-397, 3 figs. Details and uses of machine by Godfrey Eng. Works, London.

D

DIES

Automobile Parts. Making Dies for Forming Automobile Parts, Richard Dale. Iron Age, vol. 108, no. 18, Nov. 3, 1921, pp. 1127 1129, 10 figs. Explains design and construction for manufacture of such articles as brake drums and step brackets.

Carburetor Bowl. Drawing Dies for Manufacturing a Carburetor Bowl, N. T. Thurston Machy. (N. Y.), vol. 28, no. 3, Nov. 1921, pp. 218-221, 11 figs. Shows how substantial saving was effected by drawing and forming carburetor bowl on power presses. Describes successive operations.

Self-Opening Dieheads. Making the Coventry Self-Opening Diehead. Am. Mach., vol 55, no. 17, Oct. 27, 1921, pp. 678 681, 15 figs. Materials tested in an up-to-date laboratory; parts inspected and sent to storeroom for reissue after each operation. Work carried out in self-contained factory at Edgwick, Coventry, England.

Shaving Tools. Notes on the Design of Shaving Tools, Hugo F. Pusep. Am. Mach., vol. 55, nos. 16 and 17, Oct. 20 and 27, 1921, pp. 624 626 and 686 689, 18 figs. Second operation necessary to obtain accuracy of size and contour. Discusses three general classes of shaving tools.

Wire-Drawing, Diamond. Diamond Dies for Wire Drawing, C. W. Busick. Am. Mach., vol. 55, no. 18, Nov. 3, 1921, pp. 703 705, 7 figs. How dies are lapped and tested for size. Automatic lapping machines for this work.

DIESEL ENGINES

Combustion in. Explosion and Internal-Combustion Engines (Moteurs a Explosion et a Combustion Interne), F. Huard. Arts et Métiers, vol 74, no. 11, August 1921, pp 212 216, 2 figs Discusses combustion in Diesel and semi Diesel engines. (Concluded.)

Marine. A New Nelseco Diesel Engine. Motorship, vol 6, no 10, Oct. 1921, pp 798 801, 10 figs Details of 600 b hp. marine Diesel engine designed for electric and direct drives, built by New London Ship & Engine Co., Groton, Conn. Fuel consumption at 25 per cent overload is 0.42 lb. per b.hp.

Building Marine Diesel Engines. Eng. Production, vol 3, nos 53 and 51, Oct 6 and 13, 1921, pp. 321 325 and 319 352, 21 figs Methods and equipment of the North British Diesel Engine Works, Ltd., at Glasgow, founded in 1913 for purpose of developing marine Diesel engine up to 12,000 hp.

The Marine Diesel Engine. Its Reliability in Service, Andrew J Brown. Trans Inst. Mar. Engrs, vol 33, Sept. 1921, pp. 279 307 and (discussion) 307 325, 7 figs. Discusses the various parts of engine from the standpoint of showing how reliability is ensured

Worthington Solid-Injection. The Worthington Solid-Injection Diesel Power, vol 54, no. 18, Nov. 1, 1921, pp. 675 677, 3 figs Engine operating on Diesel cycle without air injection Novel means employed to secure combustion at constant pressure with pump feed.

DROP FORGING

Modern Practice. Modern Drop-forging Practice, Fred R. Daniels. Machy. (N. Y.), vol. 28, no. 3, Nov. 1921, pp. 213-217, 8 figs. Comparison of drop forgings and castings, and general methods of making them.

DYNAMOMETERS

British Traction. A New British Traction Dynamometer. Automotive Industries, vol. 45, no. 18, Nov. 3, 1921, pp. 860-861, 3 figs. Description of recording instrument designed especially for use in tractor trials; registers drawbar pull, time, and distance covered.

E

ELECTRIC DRIVE

Fabric Printing Machines. Electric Drive for Fabric Printing Machines (Commande électrique des machines a imprimer les tissus), Louis Grosheintz. La Technique Moderne, vol. 13, no. 2, Feb. 1921, pp. 71-74, 4 figs. Shows that d.c. drive is most suitable.

Lumber Mills. Application of Electrical Energy in Lumber Mills, W. A. Scott. Elec. Rev. (Chicago), vol. 79, no. 19, Nov. 5, 1921, pp. 685-688, 6 figs. Saws, conveyors and other units driven by belted and direct-connected motors; special requirements peculiar to lumber industry; mill refuse as fuel to generate electric power.

ELECTRIC FURNACES

Gray-Iron Castings. Gray Iron Castings from Electric Furnaces, Thomas Robson Hay. Iron Age, vol. 108, no. 19, Nov. 10, 1921, pp. 1214-1215. Present electric practice and advantages over older method. Comparative cost.

Induction. A New Electric Induction Furnace (Nouveau four électrique a induction), H. Vigneron. La Nature, no. 2475, Sept. 10, 1921, pp. 163-165, 5 figs. Describes Northrup system and its applications.

Iron Industry. Electric Furnace Possibilities in the Western Iron Industry, R. C. Gosrow. Jl. Electricity & Western Industry, vol. 47, no. 7, Oct. 1, 1921, pp. 265-266. Analysis of opportunities open to the electric furnace in the Western iron industry, with data on costs.

Repelling-Arc Type. Something New in Electric Furnaces, E. F. Cone. Sci. Am., vol. 125, no. 14, Oct. 1, 1921, p. 229, 1 fig. Describes repelling-arc type of furnace having a self-regulating, flaming arc torch.

Superheating Iron. Superheating Iron Electrically, George K. Elliott. Iron Trade Rev., vol. 69, no. 16, Oct. 20, 1921, pp. 1007-1011. States that by using basic-lined electric furnace in conjunction with cupola, high-temperature iron can be produced, desulphurization can be accomplished easily and impurities closely controlled. Compares composition and strength. Paper presented under auspices of Am. Foundrymen's Assn. before Instn. British Foundrymen.

ELECTRIC LOCOMOTIVES

Characteristics. Characteristics of the Electric Locomotive, N. W. Storer. Jl. Franklin Inst., vol. 192, no. 4, Oct. 1921, pp 453 467, 8 figs. Deals with d.c. and a.c. locomotives, and regenerative braking.

Comparison with Steam. Some Mechanical Characteristics of High-Speed, High-Power Locomotives, A. W. Gibbs. Jl. Franklin Inst., vol. 192, no. 4, Oct. 1921, pp. 469 495, 26 figs. Deals principally with results of comparative trial of steam and electric locomotives made in 1907 to secure information in connection with design of electric locomotives for Pennsylvania terminal in New York.

Control Equipment. Electrical Considerations Which Govern in a Choice of Locomotives for Any Given Class of Service, H. H. Johnston. Coal Age, vol. 20, no. 18, Nov. 3, 1921, pp. 717 719, 4 figs. Locomotives with dynamic-braking controllers deliver current on descending grades and must have additional motor capacity. Series-and-parallel control vs. series-parallel control.

German. New Electric Passenger-Train Locomotives for the Silesian Mountain Railway (Neue elektrische Personenzug-Lokomotiven fur die Schlesischen Gebirgsbahnen), H. Loewentraut. Elektrische Kraftbetriebe u. Bahnen, vol. 19, no. 17, Sept. 10, 1921, pp. 201 203, 2 figs. Specifications: Gage, 1435 mm.; driving-wheel diam.; 1250 mm.; leading wheel diam., 1000 mm.; max. speed, 90 km. per hr.; contact line voltage, 15,000 volts; frequency, 16⅔ periods.

Midi Railway, France. Mechanical Aspects of the New Electric Double-Bogie Locomotives of the Midi Railroad in France [Sur les dispositions mécaniques d'ensemble des nouvelles locomotives électriques a deux bogies moteurs (type de la compagnie des chemins de fer du Midi)], Fernand Broussouse. Le Technique Moderne, vol. 13, no 3, March 1921, pp. 97 101, 12 figs. Discusses French and American suspensions, interchangeability and balancing of Midi bogies, etc.

Selection. Mechanical and Engineering Considerations Determining the Selection of an Electric Locomotive, H. H. Johnston Coal Age, vol. 20, no. 17, Oct. 27, 1921, pp 679 681, 5 figs. Discusses mine-haulage equipment and their specifications, locomotives, speed, and weight of rail.

ELECTRIC PLANTS

Bangor, Me. Remodeling Plant to Increase Rating, Phifer Smith. Elec. World, vol 78, no. 17, Oct. 22, 1921, pp. 815 818, 5 figs. Describes new constructions at Veazie power plant of Bangor (Me.) Ry. & Electric Co., including four new units of 1,800 kw. capacity each.

Blackburn, England. Electricity Supply in Blackburn. Electrician, vol. 87, no. 2267, Oct. 28, 1921, pp. 536-539, 3 figs. Describes coal and ash handling plants, boiler house, turbo-alternators (two 10,000 kw. each driving 6,600-volt 50-period three-phase alternators), and auxiliaries of new power station.

Edinburgh. New Electricity Station at Edinburgh, S. B. Donkin. Electrician, vol. 87, no. 2263, Sept. 30, 1921, p. 407. Describes equipment, including generating plant, sea work pumps, shafts and tunnels. H. T. three-phase current; ultimate capacity 100,000 kw. (Abstract.) Paper read before British Assn.

England. Recent Extensions at Sunderland. Electrician, vol. 87, no. 2263, Sept. 30, 1921, pp. 414-415, 4 figs. Describes turbo-alternator, motor generators, busbar and switchboard construction of Corporation Generating Works.

Large Units. Some Notes on Large Electric Units, Stanley Parker Smith. Electrician, vol. 87, no. 2262, Sept. 23, 1921, pp. 378-380, 5 figs. Discusses prime movers, a.c. and d.c. production, converters, mercury rectifiers, etc. (Abstract.) Paper read before British Assn.

London Underground Railways. Chelsea Power Station—London Underground Railways. Tramway & Ry. World, vol. 50, no. 20, Oct. 20, 1921, pp. 185-189, 5 figs. Describes new equipment installed, including 15,000-kw. turbo-alternators, condensing water plant, etc.

Small. Economies in Operation of Small Power Plants, E. S. Hight. Elec. Rev., (Chicago), vol. 79, no. 16, Oct. 15, 1921, pp. 573-576, 3 figs. Discusses selection of coal, reduction of air leakage and radiation losses, engine room economies, etc. Extracts from paper before Iowa section of N.E.L.A.

Steel Works, Rumania. Operating Experiences with the Electric Plants of the Resita Steel Works (Rumania) (Einige Betriebserfahrungen mit den elektrischen Anlagen der Eisenwerke in Resita), Erick Beck. Elektrische Kraftbetriebe u. Bahnen, vol. 19, no. 19, Oct. 10, 1921, pp. 225-228, 2 figs. Current is supplied from three power plants; viz., one hydroelectric station, one blast-furnace-gas engine plant, and one 2500-kw. steam turbine, all supplying a single network with 5000-volt three-phase current with frequency of 20.8 periods.

ELECTRIC RAILWAYS

Italy. Valtellina Railway is Extended, E. Huldschiner. Elec. Ry. Jl., vol. 58, no. 19, Nov. 5, 1921, pp. 816-817, 1 fig. Discusses new trolley suspension and new locomotive; tests show satisfactory operation. Translated from Elektrotechnische Zeit.

Ore-Carrying, Chile. A Visit to the Tofo Mine of the Bethlehem Chile Iron Mines Co. (Una visita al mineral del Tofo de la Bethlehem Chile Iron Mines Co.), Ricardo Solar Puga. Anales del Instituto de Ingenieros de Chile, vol. 21, no. 6, June 1921, pp. 397-403, 8 figs. Describes first electric railroad in Chile used for ore carrying. Locomotives are of 1200 hp. d.c. 2400 volt.

Third-Rail System. Experiences of Northwestern Pacific Ry. with Third Rail System, C. E. Hatch. Eng. & Contracting, vol. 56. no. 16, Oct. 19, 1921, p. 380. Experiences in operation of 37 mi. of electrified track on which third-rail system is employed. Notes on how contact rail is supported; protections at crossings and stations; method of carrying feeders; and maintenance cost. (Abstract.) Paper read before Pac. Ry. Club.

ELECTRIC WELDING, ARC

Rail Joints. Arc Welded Rail Joints. Welding Engr., vol. 6, no. 10, Oct. 1921, pp. 27-32, 13 figs. Discusses welding rail joints by the Detroit street-car system and tests made.

ELEVATORS

Electrical Troubles. Locating Electrical Trouble on Elevators, William Zepernick, Power, vol. 54, no. 20, Nov. 15, 1921, pp. 755-757, 14 figs. Grounds, short circuits and open circuits defined. Methods of grounding power systems. Examples given on how to locate electrical faults on controller equipment.

EMPLOYEES

Thrift Encouragement by Employers. Thrift Encouragement by Employers V. Leonhard Felix Fuld. Indus. Management, vol 62, no 5, Nov. 1921, pp. 287 289. Points out that investment companies appear to be ideal thrift encouragement plan for workers, as they furnish a thrift encouragement vehicle for each class of worker.

EMPLOYEES, TRAINING OF

Selection and. Industrial Training and Selection of Personnel, C R. Dooley Chem. & Met. Eng., vol. 25, no 15, Oct. 12, 1921, pp. 692 695. Outline of basic principles underlying modern methods of selecting and training employees, and some helpful suggestions for solving personnel problems.

ENAMELING

Steel Containers. Enamel-Lined Apparatus, Chester H. Jones. Chem. & Met. Eng., vol. 25, no. 20, Nov. 16, 1921, pp. 927-932, 17 figs. Plant of Elyria Enameled Products Co. at Elyria, Ohio, engages in manufacture of enameled equipment for service in many varieties of plant processing; steel and cast-iron containers; burning equipment; composition and properties of enamels; control and management of operations.

EVAPORATORS

Design. An Improvement in Evaporator Design, Robert V. Cook. Chem. Age (N. Y.), vol. 29, no. 10.

Oct. 1921, pp. 409–410, 1 fig. Describes the criss-cross evaporator.

Tests. Result of Operations With Some Evaporators (Resultats de marche de quelques appareils d'evaporation), M. Depasse. Bul. de l'Association des Chimistes de Sucrerie et de Distillerie, vol. 38, no. 10, April 1921, pp. 383–404 and (discussion) 407–409, 2 figs. Gives test data with two-stage, three-stage, and four-stage evaporators.

F

FACTORIES

Hosiery. Up-to-the-Minute Design for New Hosiery Factory, H. P. Elliott. Contract Rec., vol. 35, no. 45, Nov. 9, 1921, pp. 963–967. Plant of Holeproof Hosiery Co. of Canada, Ltd., London, Ont., is said to combine every feature that will make employees comfortable and efficient. Details of heating and ventilating, boiler house, hot-water supply, water-softening plant, illuminating system, power transmission, telephone, electric time clocks, etc.

Planning Operations. Notes on the Preparation of Work Lay Outs, H. Varley. Eng. & Indus. Management, vol. 3, no. 37, Nov. 3, 1921, pp. 491–494, 9 figs. Writer enumerates points which should be carefully considered when a part is to be laid out in operations.

Rubber Tires. Mechanical Features of Tire Factory. Iron Age, vol. 108, no. 20, Nov. 17, 1921, pp. 1259–1265, 8 figs. New Kelly-Springfield plant is said to have unusually complete interconnection of mechanical services. Notes on tunnels, piping, wiring and communication.

FACTORY MANAGEMENT

See INDUSTRIAL MANAGEMENT.

FANS, CENTRIFUGAL

Design. Controlling Factors in Fan Design, David Darrin. Heat & Vent. Mag., vol. 18, no. 10, Oct. 1921, pp. 49–52. Discusses required capacities, available space and attendance, allowable first cost and operating cost, etc., and gives table of present standards of fan design.

Electrically Driven. Electrically Driven Centrifugal Fans for Mine Ventilation. Mech. World, vol. 70, no. 1815, Oct. 14, 1921, pp. 303–304. Discusses characteristics of fans and motors, power requirements, etc.

Heaters and. Fans and Heaters, Charles L. Hubbard. Southern Engr., vol. 36, no. 2, Oct. 1921, pp. 44–49, 12 figs. Working data for fans, fan drives; heaters; determining size of heater, heater arrangements; heater connections, ducts and flues.

FATIGUE

Industrial. Physiological Methods for Measuring Industrial Fatigue (Les Méthodes Physiologiques actuelles d'évaluation de la Fatigue dite "Industrielle"), D. Glibert. Annales des Mines de Belgique, vol. 22, no. 3, 1921, pp. 837–847, 1 fig. Concludes that present methods are not strictly applicable.

Reduction. Reducing Fatigue in Tool Rooms, F. B. and L. M. Gilbreth. Iron Trade Rev., vol. 69, no. 16, Oct. 20, 1921, pp. 1004–1006, 7 figs. Orderly arrangement of tools, conveniently placed shelves and drawers, and white surfaces tend to improve conditions in tool crib. Ample sunlight important. (Abstract.) Paper before Soc. Indus. Engrs.

Tests. Fatigue Tests at Purdue University, George H. Shepard. Indus. Management, vol. 62, no. 5, Nov. 1921, pp. 281–286, 4 figs. How exertion and rest periods affect efficiency. Includes chart showing output in foot-pounds under certain conditions of work and rest periods.

FILING SYSTEM

Classification, Indexing and. Classification, Filing and Indexing System for Pulp and Paper Library, Carleton E. Curran. Paper, vol. 28, nos. 19, 20 and 21, July 13, 20 and 27, 1921, pp. 9–11, 23 and 30, pp. 17–19 and pp. 17–18. Gives an adaptation of the Dewey classification.

FLIGHT

Soaring. Soaring Flight, L. Prandtl. Aviation, vol. 11, no. 16, Oct. 17, 1921, p. 459, 1 fig. Discusses soaring of birds and possibilities of human soaring flight. Translated from Zeitschrift für Flugtechnik und Motorluftschiffahrt, July 30, 1921.

Some Remarks Concerning Soaring Flight, L. Prandtl. Flight, vol. 13, no. 38, Sept. 22, 1921, pp. 633–634. Utilization of wind power in gliding planes. Translated from Zeitscrift für Flugtechnick und Motorluftschiffahrt, July 30.

The Rhön Soaring Flight Contest 1921 (Rhön-Segelflug-Wettbewerb 1921), Werner v. Langsdorff. Zeit. für Flugtechnik u. Motorluftschiffahrt, vol. 12, no. 18, Sept. 30, 1921, pp. 278–281. List and data of competing machines and account of performances.

Spinning Curves. Flight and Spinning Curves (Flug- und Trudelkurven), Ludwig Hopf. Zeit. für Flugtechnik u. Motorluftschiffahrt, vol. 12, no. 18, Sept. 30, 1921, pp. 273–278, 9 figs. Discusses equilibrium in connection with stationary curve flight (spinning curve).

FLOW OF AIR

Phenomena. Flow Phenomena in Free Air Currents (Ueber die Strömungsvorgänge), Walter Zimm. Forschungsarbeiten auf dem Gebiete des Ingenieurwesens, no. 234, 1921, 36 pp., 31 figs. Investigation of flow phenomena in air currents of low velocity which are said to be of physical and technical importance. Description of experimental apparatus and results of experiments.

FLOW OF FLUIDS

Laminary Limit Flow. The Approximative Integration of the Differential Equation of the Laminary Limit Flow (Zur näherungsweisen Integration der Differentialgleichung der laminaren Grenzschicht), K. Pohlhausen. Zeit. fur angewandte Mathematik u. Mechanik, vol. 1, no. 4, Aug. 1921, pp. 252–268, 10 figs. An integration method is developed and examples are given to demonstrate its applicability.

Laminary and Turbulent Friction. Laminary and Turbulent Friction (Ueber laminare und turbulente Reibung), th. v. Kármán. Zeit. fur angewandte Mathematik u. Mechanik, vol. 1, no. 4, Aug. 1921, pp. 233–252, 7 figs. Discusses theory of laminary friction of liquids and gases in pipes, in connection with which author seeks to explain from mathematical and physical viewpoint the basic principle of Prandtl's limit flow theory and suggests a method for simple mathematical calculation of even complicated cases, he seeks also to develop mathematical basis for turbulent friction.

FLUE-GAS ANALYSIS

Numerical Calculation. The Evaluation of Flue-Gas Analysis (Die Auswertung der Rauchgasanalyse), A. B. Helbig. Feuerungstechnik, vol. 9, no. 24, Sept. 15, 1921, pp. 229–234. Based on calculation of decomposition of all combustible components of fuel with exception of carbon monoxide in atomic volumes, a formula applicable to all fuels is developed which permits an entirely new, simple and clear calculation of heat, according to which carbon loss is determined in purely mathematical manner, and which also permits a new criterion of fuels.

Testing Apparatus. Apparatus for Testing Flue-Gas, John B. C. Kershaw. Combustion, vol. 5, no. 5, Nov. 1921, pp. 204–207 and 218, 9 figs. Describes seven gas-testing instruments which depend upon the measurement of some physical property of waste-gases, which also serves as an index of the amount of CO_2 contained in them.

FORGE PLANTS

Safety Guards in Shops. Using Safety Devices in Forge Shops. Iron Trade Rev., vol. 69, no. 19, Nov. 10, 1921, pp. 1216–1217, 6 figs. Describes simple and inexpensive guards which are being used in one shop.

FOUNDATIONS

Steam Power Plants, etc. Some Notes on Foundation Plans, Douglas Wilson. Mech. World, vol. 70, no. 1816, Oct. 21, 1921, pp. 327–328, 6 figs. Discusses foundations for prime movers, steam power installations, steam turbines, concrete and reinforcement.

FOUNDRIES

Equipment. Equipment Features Malleable Shop, H. E. Diller. Foundry, vol. 49, no. 20, Oct. 15, 1921, pp. 805–813, 14 figs. Discusses changes made in conveying, melting and annealing at new foundry of Am. Chain Co., York, Pa.

Steel. Famous British Works. Eng. Production, vol. 3, no. 54, Oct. 13, 1921, pp. 338–339, 2 figs. Details of plant and equipment of steel foundry of Edgar Allen & Co., Ltd., Tinsley, for production of high-speed, carbon and alloy tool steels, special alloy steels for automobiles and aircraft, toughened steel castings for engineering and other purposes, dynamo magnet-steel castings, Imperial manganese steel, etc.

Temperature Problems. Temperature Problems in Foundry and Melting Room, John P. Goheen. Trans. Am. Inst. Min. & Metallurgical Engrs., no. 1105-N, 1921, 5 pp. Notes on pyrometer equipment for electric brass-melting furnace; special equipment for brazing brass; core-oven temperature control; and value of annealing. Abstract in Min. & Metallurgy, no. 179, Nov. 1921, p. 36.

FUELS

Gaseous. Gaseous Fuel in the Shipbuilding World, George Keillor. Gas Jl., vol. 156, no. 3047, Oct. 5, 1921, pp. 34–37. Discusses application in annealing, hardening and normalizing. Billet, plate and rivet heating; core and mold drying; fuel consumption. See also Iron & Coal Trades Rev., vol. 103, no. 2796, Sept. 30, 1921, pp. 476–478.

Lumber Refuse. Consumers Central Heating Company's New Hog-Fuel Burning Plant. Power, vol. 54, no. 20, Nov. 15, 1921, pp. 750–753, 6 figs. Hog fuel, consisting of sawdust, shavings, groundup edgings, slabs and trimmings, is purchased from lumber manufacturing plants for fuel. Three 7500-sq. ft. vertical water-tube boilers installed. Fuel delivered by barges and handled by 5-ton electric monorail-operated clamshell bucket to system of conveyors.

Smokeless, Manufacture of. The Manufacture of Smokeless Fuel. Engineering, vol. 112, no. 2913, Oct. 28, 1921, pp. 596–601, 41 figs., partly on supp. plate; also Engineer, vol. 132, no. 3135, Oct. 28, 1921, p. 461, 3 figs. Describes works of low Temperature Carbonization, Ltd., Barugh, England, which has 20 retorts in continuous service and are carbonizing 36 tons of coal daily. Fuel produced is sort of semi-coke carrying only very small proportion of breeze, and is called coalite.

[See also OIL FUEL; PULVERIZED COAL.]

FURNACES, BOILER

Forced-Draft Grates. New Forced-Draft Furnace Grate (Crux-Rost und -Ventisolotor), H. Pradel. Elektrotechnischer Anzeiger, vol. 38, no. 153, Sept. 27, 1921, pp. 1096–1098, 7 figs. Describes forced-draft grate and direct-operating mechanical induced-draft installations recently placed on market by Hans Cruse & Co., Berlin.

FURNACES, HEATING

Reheating. The Development and Perfection of the Reheating Furnace (Der Tiefherdofen, seine Entwicklung und Vervollkommnung), A. Sattmann. Feuerungstechnik, vol. 9, no. 23, Sept. 1, 1921, pp. 217–219, 2 figs. Notes on operation and advantages of such furnaces.

FURNACES, INDUSTRIAL

Oil Burners. The "Rotamisor" Oil-Fuel Burner. Engineering, vol. 112, no. 2914, Nov. 4, 1921, pp. 631–632, 4 figs. Describes burner constructed by Combustions, Ltd., Kingston-on-Thames, most interesting feature of which is said to be method adopted for atomization. It is being developed to all requirements from heating of small muffle furnaces for tempering, etc., to firing of large marine or stationary boilers.

FURNACES, METALLURGICAL

Smelting. Smelting Furnace Practice with Regard to Different Construction Types and Present Conditions (Der Schmelzofenbetrieb unter Berücksichtigung der verschiedenen Ofenkonstruktionen und der heutigen Verhaltnisse), Carl Rein. Giesserei-Zeitung, vol. 18, nos. 22 and 23, Sept. 6 and 13, 1921, pp. 296–300 and 312–314, 12 figs. Author records his experiences since 1919, and discusses furnace systems, charging methods and devices, and removal of iron. Points out noticeable defects in present smelting practice and furnaces and offers suggestions for their elimination. Address before Assn. German Foundrymen.

Tar-Oil-Fired. German Furnaces Fired with Tar-Oil, Kuenscher. Foundry, vol. 49, no. 19, Oct. 1, 1921, pp. 770–771. (Abstract.) Paper read before Assn. of German Non-ferrous Metal Founders.

G

GAGES

Manufacturing Uses. The Need of Gauges for Modern Manufacturing, A. C. Wickman. Can. Machy., vol. 26, no. 13, Sept. 29, 1921, pp. 25–29, 8 figs. Discusses the subject of gaging screws, and the checking of gages.

McLeod. An Extension of the Range of the McLeod Gauge, A. H. Pfund. Physical Rev., vol. 18, no. 1, July 1921, pp. 78–82, 2 figs. The pressure of the gas forced into capillary is measured by means of a hot-wire gage. The ratio of compression being known, the time pressure can be determined.

Precision. Precision Gauges, M. E. Kanek. Mech. World, vol. 69, no. 1782, Feb. 25, 1921, pp. 139–141. Discusses 81-block sets, types on the market, effect of size on accuracy, material for gages, direct and comparative methods of measuring, etc.

Snap. Systems of Gauging. Eng. Production, vol. 3, no. 54, Oct. 13, 1921, pp. 345–346, 2 figs. Describes an adjustable snap gage and setting micrometer, which is said to be adaptable and inexpensive.

GAS PRODUCERS

Fuel Economy. Fuel Saving in Modern Gas Producers and Industrial Furnaces, W. B. Chapman. Mech. Eng., vol. 43, no. 11, Nov. 1921, pp. 717–621, 7 figs. Calls attention to fuel wastes in industries using gas producers and producer-gas furnaces, reviews progress in last 25 years in gas-producer construction, and describes distinctive type of recuperative furnace and extension of its use to pulverized coal and oil. (Abstract.)

GEAR CUTTING

Gear Shapers. Production Shaping. Machy. (N. Y.), vol. 28, no. 3, Nov. 1921, pp. 186–190, 10 figs. Use of shapers in production work in machine-tool building plants.

Machines. An Improved Gear Generating Machine. Eng. Production, vol. 3, no. 57, Nov. 3, 1921, pp. 412–415, 7 figs. Details of novel design for helical, straight and internal gears.

GEARS

Erosion in High-Speed. Pitting in High-speed Gearing. Machinery (Lond.), vol. 19, no. 472, Oct. 13, 1921, pp. 50–51, 2 figs. Discusses new method developed to eliminate pitting or erosion in teeth of wheels.

Hardening under Pressure. Hardening Gear Under Pressure. Eng. Production, vol. 3, no. 57, Nov. 3, 1921, pp. 426–427, 3 figs. Describes new method.

Involute. The Evolution of the Involute Gear Tooth—VIII and IX, A. Fisher. Machinery (Lond.), vol. 19, nos. 474 and 475, Oct. 27 and Nov. 3, 1921, pp. 101–103, 6 figs. and pp. 132–136, 7 figs. Involute pitch and pressure angle permutability.

Non-Metallic. Design and Manufacture of Non-metallic Gears. Machinery (Lond.), vol. 19, no. 471, Oct. 6, 1921, pp. 6–11, 12 figs. Discusses preparation of rawhide and fabric-base gear materials physical characteristics, design and machining of gear.

Power-Transmission. Gear Tooth Problems (Beitrag zur Zahnradfrage für Uebersetzungsgetriebe), O. Lasche. Zeit. des Vereines deutscher Ingenieure, vol. 65, no. 42, Oct. 15, 1921, pp. 1087–1088, 8 figs. Based on examples of gear teeth for marine and land installations, values for tooth loads and speeds are developed. Sliding conditions with standard and AEG (German Gen. Elec. Co.) teeth are compared. Suggests means of obtaining a neater and more accurate tooth.

Spur. The Production of Spur Gears, R. Waring-Brown. Eng. Production, vol. 3, no. 55, Oct. 20, 1921, pp. 364–368, 8 figs. and (discussion), no. 56, Oct. 27, 1921, pp. 389–391. Comparison of modern methods. Paper presented before Instn. Production Engrs.

Spur, Hobbed, Backlash in. Backlash in Hobbed Spur Gears, Carl G. Olson. Machy. (N. Y.), vol. 28, no. 3, Nov. 1921, pp. 222–224, 5 figs. Amount of backlash recommended to provide for unavoidable inaccuracies in machining and heat treatment.

Sykes Gear-Tooth Comparator. The Sykes Gear-Tooth Comparator. Mech. World, vol. 70, no. 1814, Oct. 7, 1921, pp. 280–282, 4 figs. May be used for comparing and definitely measuring thickness of teeth, for comparing uniformity of pitch and for ascertaining amount of inaccuracy of tooth shape.

GOVERNORS

Shaft, Adjusting. Adjusting Shaft Governors. Power, vol. 54, no. 17, Oct. 25, 1921, pp. 641–647, 16 figs. Shows how to adjust different types of governors.

GRINDING MACHINES

Surface. Economy of Surface Grinding Machines (Wirtschaftlichkeit der Flächenschleifmaschinen), F. Warsow. Betrieb, vol. 3, no. 25, Sept. 15, 1921, pp. 829–832, 6 figs. Describes machines equipped with grinding cylinders for economical machining of various flat pieces from the rough. Comparison of results show a much higher efficiency with described machines than with those operating with circumferential grinding disks with equal neatness and precision.

H

HANDLING MATERIALS

Equipment. A Survey of Material-Handling Equipment, R. H. McLain. Chem. Age (N. Y.), vol. 29, no. 10, Oct. 1921, pp. 427–431, 25 figs. Suggestions for the use of labor-saving devices in chemical manufacture.

HANGARS

Cape May. Cape May Hangar for Dirigible Built From Two Small Ones. Eng. News-Rec., vol. 87, no. 17, Oct. 27, 1921, pp. 698–700, 4 figs. Sheds at Montauk and Cape May reërected on new base sections to produce hangar of greater capacity.

Suspended Roofs. Large Roofs Suspended by Cables To Avoid Columns. Eng. News-Rec., vol. 87, no. 17, Oct. 27, 1921, pp. 638–639, 4 figs. Novel design of airship sheds, giving unobstructed full-length side openings. Translated from Génie Civil.

HEAT TRANSMISSION

Bibliography. Bibliography on Heat Transmission. Am. Soc. Refrig. Engrs. Jr., vol. 8, no. 2, Sept. 1921, pp. 150–162.

Theory for Turbulent Streams. Transmission of Heat from Solid Bodies to Turbulent Liquid or Gas Streams (Der Wärmeübergang an einen turbulenten Flüssigkeits- oder Gasstrom), H. Latzko. Zeit. für angewandte Mathematik u. Mechanik, vol. 1, no. 4, Aug. 1921, pp. 268–290, 10 figs. Based on laws of velocity distribution of turbulent streams developed by Prandtl and v. Kárman, attempt is made to develop systematically a theory of heat transmission for turbulent streams and of dependence of heat-transmission coefficient on shape and dimensions.

HEATING, ELECTRIC

Arc and Resistance. Arc vs. Resistance Heating (Lichtbogen- oder Widerstandsbeheizung), H. Wintermeyer. Elektrotechnischer Anzeiger, vol. 38, nos. 155, 156, 147 and 158, Sept. 29, Oct. 1, 4 and 5, 1921, pp. 1109–1110, 1115–1116, 1125–1126 and 1133–1134, 8 figs. Discusses most important features in connection with industrial arc and high- and low-current resistance heating.

Gas Heating vs. Comparison of Gas and Electric Heating (Comparaison du chauffage au gas et a l'électricité, A. Grebel. Le Génie Civil, vol. 79, no. 12, Sept 17, 1921, pp. 249–252. Compares 1 kg. of coal transformed with low tension electricity and into gas and by-products. Shows that cost of production is in favor of gas.

HEATING, HOT-WATER

Electric. Electric Hot-Water Heating Plants with Heat Storage for Schoolhouses (Elektrische Warmwasser-Heizanlagen mit Wärme-Akkumulierung für Schulhäuser). Schweizerische Bauzeitung, vol 78, no. 13, Sept 24, 1921, pp 151–153, 7 figs. Describes hot-water heating system installed in two schoolhouses in Aarau, Switzerland, in which electric current of 4000 volts is employed. Points out success and advantages of system.

HEATING, STEAM

Isolated Power Plant. Heating and Its Relation to Isolated-Plant Operation, E. L. Wilder. Power, vol. 54, no 20, Nov. 15, 1921, pp. 758–761, 8 figs. Discusses factors that make for efficiency and inefficiencies in a combined power and heating plant.

Radiation, Calculation of. Radiation Calculation Charts, D. N. Crosthwait, Jr. Heat. & Vent. Mag., vol. 18, no 10, Oct. 1921, pp. 27–29, 2 figs. Gives tables of square feet of direct cast iron steam radiation for heat loss through two pane windows, and through wall area, room temperature 70 deg. fahr. and outside temperature 0 deg. fahr. and explains application.

Stationary Heat Storage. A Steam Heating Plant with Stationary Heat Storage (Eine Dampfheizanlage mit festem Wärmespeicher), M. Hottinger. Schweizerische Bauzeitung, vol. 78, no. 10, Sept. 3, 1921, pp. 124–126, 2 figs. Results of tests carried out on electric heating installation in spinning mill of H. Buhler & Cie., Sennhof, Switzerland, described in previous issue of same Journal (July 17, 1920).

Vacuum. Operation and Advantages of Vacuum Steam-Heating Systems (Vorzüge und Wirkungsweise der Vakuumdampfheizungen). Elektrotechnischer Anzeiger, vol. 38, nos. 161 and 162, Oct. 11 and 12, 1921, pp. 1158–1160 and 1164–1165. Said to be especially adapted to small and medium-size factories.

HOBS

Gear. Inspection of Involute Spur and Helical Gear Hobs. Machinery (Lond.), vol. 19, no. 474, Oct. 27, 1921, pp. 90–95, 19 figs. Testing accuracy of hob and tooth parts; hobbing test.

HOISTING MACHINES

Safeguards. Hoisting and Conveying. Power Plant Eng., vol. 25, no. 20, Oct. 15, 1921, pp. 1000–1003. Machinery safeguards and safe operation.

HOT-WATER SUPPLY

Water-Temperature Control. Determination of Hot Water Requirements, William Wilcox. Heat. & Vent. Mag., vol. 18, no. 10, Oct. 1921, pp. 31–35, 7 figs. Essential points to be considered, with data on apartment houses and various methods of water-temperature control.

HOUSES

Wall Construction. Design and Construction of Dwelling House Walls, Carroll Beale. Concrete Products, vol. 21, no. 4, Oct. 1921, pp. 51–52. Discusses types of construction, including concrete. Reprinted from Contractor's Atlas.

HOUSING

Garden City Scheme, London. Building Garden-Cities at the London Conférence (La Construction des Villeset Cités-Jardins a la conference de Londres), M. De Heem. Annales des Travaux Publics de Belgique, vol. 22, no. 4, August 1921, pp. 595–626, 11 figs. Partly on supp. plates. Discusses the housing question and recent competition in designs in London. Gives illustrations.

Sherbrooke, Can. Housing Developments in Sherbrooke. Contract Rec., vol. 35, no. 45, Nov. 9, 1921, pp. 968–969, 8 figs. Model city built to house workers of Canadian Connecticut Cotton Mills.

HYDRAULIC MACHINERY

Packing Friction. Experiments with Packing Friction (Versuche über Stulpenreibung), Eugen Irion. Zeit. des Vereines deutscher Ingenieure, vol. 65, no. 39, Sept. 24, 1921, pp. 1016–1017, 2 figs. Results of tests on a 75-ton drop and bending machine with hydraulic gage connected directly to working cylinder. Comparison with values determined by Martens. Advantages of the simplified pressure measurement with measuring cylinders.

HYDRAULIC TURBINES

Draft Tubes. Draft Tubes—How They Operate and Why. Power, vol. 54, no. 16, Oct. 18, 1921, pp. 600–604, 17 figs. Elementary, non-mathematical explanation of hydraulic draft tubes. Use of barometer and "scenic railway" to illustrate fundamental principles involved.

Kaplan. Design and Use of the Kaplan Turbine (Die Kaplanturbine in Ausführung und Verwendung), C. Reindl. Zeit. des Vereines deutscher Ingenieure, vol. 65, nos. 40 and 41, Oct. 1 and 8, 1921, pp. 1035–1040 and 1066–1069, 33 figs. Deals with development and details, including rotars, guide vanes, draft tubes, single and double turbines. Experimental results and behavior under different operating conditions. Useful possiblities and advantages.

Speed Regulation. Speed Regulation of Hydraulic Turbines, John S. Carpenter. Power Plant Eng., vol. 25, nos. 19 and 20, Oct. 1 and 15, 1921, pp. 947–950 and 990–993, 5 figs. Principles and methods of calculation involved in design of hydraulic turbine governors.

Speed Regulation in the Hydraulic Plant, N. L. Devendorf. Power, vol. 54, no. 20, Nov. 15, 1921, pp. 764–767, 6 figs. Conditions that must be met by waterwheel governor. Development from early flyball governor to present oil-pressure type. Requirements of low-head versus high-head plants. Operating in parallel

HYDROELECTRIC DEVELOPMENT

Belgium. Utilizing Hydraulic Resources of Belgium (Avant-Projet de captation des energies hydrauliques Belges), Herman Chauvin. Révue Universelle des Mines, vol. 11, no. 1, Oct. 1, 1921, pp. 1–28, 9 figs. Describes Ardennais works, reservoirs, dams, canals, power plants, their cost, capacity, equipment, etc.

Colorado River. Electrical Construction Plan for Colorado River, Charles Heston Peirson. Elec. Rev. (Chicago), vol. 79, no. 16, Oct. 15, 1921, pp. 586–588. Comprehensive development proposed to regulate stream flow for utilization of available water power.

Switzerland. Plans for Hydroelectric Development in the Bernese Oberland (Les projets des Forces Motrices Bernoises dans l'Oberhasle), Jean Ganguillet. Schweiz. Elektrotechnischer Verein Bul., vol. 12, no. 8, Aug. 1921, pp. 209–216, 2 figs. Presents plans for harnessing the Aar River and for developing in Oberhasle the future greatest source of electric energy in Switzerland.

HYDROELECTRIC PLANTS

California. Progress on Pit River Project in California. Eng. News-Rec., vol. 87, no. 15, Oct. 13, 1921, pp. 604–606, 1 fig. First plants completed. Features of development will be 220,000-volt transmission line, 7-mi., 3000-sec-ft. tunnel on Pit River No. 5, and 40,000-hp. reaction turbines under 454-ft. head in Pit River No. 1.

Great Falls, Conn. Great Falls Hydro-Electric Development. Power Plant Eng., vol. 25, no. 20, Oct.15, 1921, pp. 981–986, 11 figs. Describes equipment of Falls Village hydroelectric plant of Conn. Power Co., on Housatonic River, supplying normally 10,000 kw. at 66,000 volt, to main lines.

Italy. Hydroelectric Plants in Southern Italy (Gli impianti idroelettrici del Mezzogiorno d'Italia), Emirico Vismara. L'Elettricista, vol. 10, no. 18, Sept. 15, 1921, pp. 137–140, 4 figs. Discusses power transmission problems in connection with irrigation.

Maximum Rates. Determination of Maximum Rates for Hydroelectric Power Centrals (La fixation des tarifs maxima dans les cahiers des charges des concessions d'énergie hydraulique), G. Tochon. Révue Générale de l'Électricité, vol. 10, no. 13, Oct. 1, 1921, pp. 451–455. Discussion of standard specification for maximum rates proposed by Ministry of Public Works.

Sicily. Brief Description of the Works of the Societa Generale Elettrica of Sicily (Descrizione sommaria degli impianti della Societá Generale Elettrica della Sicilia). L'Elettrotecnica, vol. 8, no. 27, Oct. 5, 1921, pp. 604–610, 9 figs. Discusses hydroelectric construction, power houses and equipment, and system of transmission lines.

I

ICE PLANTS

Brine Agitation. Modern Propeller Design for Brine Agitation and Circulation, E. A. Burrows. Am. Soc. Refrig. Engrs. Jl., vol. 8, no. 2, Sept. 1921, pp. 127–133 and (discussion) 133–134, 10 figs. Describes experiments with Halvorsen propeller, reducing power consumption from 25 to 50 per cent.

INDEXES

Construction and Comparison. Details of Index Number Construction and Comparison of Indices, E. E. George. Eng. & Contracting, vol. 56, no. 19, Nov. 9, 1921, pp. 431–434, 3 figs. Notes on volume of production index. Bradstreet's, Dun's, and Federal Reserve Board index, standard and tests, and cost-of-living indexes.

INDUSTRIAL MANAGEMENT

Distribution of Manufacturing Expense. The Distribution of Manufacturing Expense, C. Haigh. Can. Machy., vol. 26, no. 15, Oct. 13, 1921, pp. 34–36. Discusses five methods for distributing overhead expense: man-rate; man-hour; material and labor; sold-hour; and machine-hour rate.

Factory Investigation. How Factory Investigations Reduce Costs, Albert A. Dowd and Frank W. Curtis. Machy. (N. Y.), vol. 28, no. 3, Nov. 1921, pp. 208–212, 7 figs. Discusses effect of design upon cost of machining and gives examples of savings realized by change of design; savings effected in drilling, and by use of punch press.

Instruction Sheets. Proposals for New Factory Instruction Sheets (Entwürfe neuer Betriebsblätter). Betrieb, vol. 3, no. 25, Sept. 15, 1921, p. 160. Proposal of Works Dept. of German Federation of Technical and Scientific Societies for care and handling of automobile tires.

Proposals for New Factory Instruction Sheets (Entwürfe neuer Betriebsblätter). Betrieb, vol. 3, no. 26, Sept. 25, 1921, pp. 166–168. Proposals of Works Dept. of German Federation of Technical and Scientific Societies for care and handling of precision ball and roller bearings; installation, operation and care of transmissions.

Material Control. Material Control for the Small Industrial Plant, Henry C. Haskell. Indus. Management, vol. 62, no. 5, Nov. 1921, pp. 271–273, 1 fig. Describes simple, direct and logical method of approaching problem. Includes illustration of stock card used in system which includes material costing, ordering and planning.

Purchasing Department. Purchasing. A. B. Johnson. Paper, vol. 28, no. 19, July 13, 1921, pp. 17–19, 28 and 38. Discusses work and organization of purchasing departments. Paper read before Superintendents' Assn.

Scientific. Scientific Management XXXII, Henry Atkinson. Eng. & Indus. Management, vol. 6, no. 15, Oct. 13, 1921, pp. 400–401 and 403. Failures of scientific management and their cause.

Stores Records. Machine-Posted Balance of Stores Records, C. Moffitt Ford. Bul. Taylor Soc., vol. 6, no. 4, August 1921, pp. 139–152, 4 figs. Discusses mechanical equipment and card design; posting of cards; method of proof; filing, posting and verifying routine; etc. Paper read before Phila. Section of Taylor Soc

Tool Handling. The Handling of Metal-Cutting Tools (Die Behandlung der Werkzeuge in derFabrik), A. Fattler. Zeit. des Vereines deutscher Ingenieure, vol. 65, no. 41, Oct. 8, 1921, pp. 1063–1065, 3 figs. Notes on materials for tools; storage and distribution in factory; repair and renewal: hardening of tools.

[See also TIME STUDY.]

INDUSTRIAL ORGANIZATION

Reorganizing Small Works. Reorganizing the Small Works, H. N. Munro. Eng. & Indus. Management, vol. 6, no. 17, Oct. 27, 1921, pp. 459–462, 9 figs. Writer demonstrates importance of forming clear idea of conditions of working, capabilities of staff, and proper location and layout of plant, in describing practical system of reorganization. Notes on planning organization chart.

Stimulating Interest of Workers. Making Work Fascinating as the First Step Toward Reduction of Waste, Walter N Polakov Mech Eng, vol 43, no. 11, Nov. 1921, pp 731–734 and 765, 7 figs. Points out that such experiments as have been already conducted to uniting brain work with manual work have proved beyond any doubt that such a course liberates dormant or suppressed creative capacities of men, improves quality and quantity of production, and, above all substantially ameliorates industrial relations. Advantages to owner and labor groups are set forth. (Abstract.)

INDUSTRIAL RELATIONS

Coöperation. Experiments in Industrial Coöperation. Iron Age, vol 108, no 19, Nov 10, 1921, pp. 1207 1208. Constructive solutions of employer-employee relations presented at meeting of Acad of Political Science.

Economic Axioms. The Economic Axioms of Industry. E W Petter. Eng. & Indus. Management, vol 6, no 18, Nov 3, 1921, pp. 500–502. Notes on creation and unequal distribution of wealth, community's well-being, employer and worker, piece-work rates, unemployment doles and waste, how the State can assist. (Abstract.) Lecture arranged by Indus. League & Council.

Human Factor. The Human Factor in Industry—II, Clarence H. Northcott. Indus Management, vol. 62, no. 5, Nov 1921, pp 292 297, 4 figs. Points out importance of weighing physical and mental differences and study of job in vocational selection. Discusses motion study, fatigue, rest periods, etc.

Industrial Court, Great Britain. The Industrial Court of Great Britain and Ireland, R W. Patmore. Indus Management, vol. 62, no 5, Nov. 1921, pp. 269 271. Its history, functions and personnel.

INTERNAL-COMBUSTION ENGINES

Carburation. Study of Carburation, Thermodynamics of the Explosion Engine (Introduction à l'etude de la carburation, pyrodynamique du moteur à explosions), M Carbonaro. Memoirs et Compte Rendu des Travaux de la Société des Ingenieurs Civils de France, vol 74, no 4 5–6, April-June 1921, pp. 185–249, 13 figs. Discusses deflagration at constant pressure, ignition temperature, flame propagation and its velocity, etc.

Cooling-Water Systems. Cooling-Water Systems for Internal Combustion Engines, Edgar J. Kates. Power, vol. 54, no. 20, Nov. 15, 1921, pp. 710 713, 4 figs. Notes on quality of water use of cooling tanks; open cooling systems and their faults, inclosed cooling systems.

Increasing Power Output. Petrol Engine Performance. Times Eng. Supp., no. 564, Oct. 1921, p. 277. Notes on increasing power output.

Supercharging. Supercharging Engines, C. H. T. Alston. Automobile Engr., vol. 11, no. 155, Oct. 1921, pp. 337–341, 2 figs. Discusses advantages and disadvantages; its application to aircraft, road motor vehicles, marine, stationary, and portable engines, etc.

[See also AIRPLANE ENGINES; DIESEL ENGINES; KEROSENE; OIL ENGINES, SEMI-DIESEL ENGINES.]

IRON

Gray, Oxygen in. Discusses Problems of the Foundry, J. Shaw. Foundry, vol. 49, no. 19, Oct. 1, 1921, pp. 759–761. Discusses differing view of metallurgists regarding effect of oxygen in gray iron. Methods of making physical tests and their effects on results are pointed out.

Oxygen in, Determination. A New Method for the Determination of Oxygen in Iron (Ueber ein neues Verfahren zur Bestimmung des Sauerstoffs im Eisen), P. Oberhoffer and O. von Keil. Stahl u. Eisen, vol. 41, no. 41, Oct. 13, 1921, pp. 1449–1453, 6 figs. By employment of new method, iron- and manganese-oxygen compounds in all mixture proportions can be completely reduced, with iron- and silicium-oxygen, compounds, whose silicic-acid contents do not exceed 20 per cent, at least 93 per cent of total oxygen content can be reduced.

Pig and Cast, Composition of. Composition of Pig Iron and of Cast Iron, Y. A. Dyer. Iron Age, vol. 108, no. 20, Nov. 17, 1921, pp. 1267–1270. Chemical and structural composition. Various elements, their characteristics and effect on metal. Oxygen in iron.

IRON AND STEEL

Tests. Experiments on Properties of Iron and Steel to Resist Wear (Undersökning rörande järns och ståls samt en del andra kroppars förmåga att motstå nötning), J. A. Brinell. Jernkontorets Annaler, vol. 105, no. 9, 1921, pp. 347–398, 22 figs. Describes series of tests made, and abrasives used; gives table of results.

IRON CASTINGS

Reversed Chilled. Steel Addition to Pig Iron and Reversed Chilled Casting (Stahlzusatz zum Roheisen und der umgekehrte Hartguss), E. Piwowarsky. Giesserei-Zeitung, vol 18, no. 26, Oct. 3, 1921, pp. 356–359, 7 figs. Writer seeks to establish relation between chemical analyses and the congealing diagram of iron-carbon alloys. Bibliography.

IRON, PIG

Mixer. Pig Iron Mixer. Eng. Progress, vol. 2, no. 10, Oct. 1921, pp. 227–230, 8 figs. Advantages of mixing process, rolling and tilting mixer; electrical tilting device.

Synthetic. Synthetic Foundry Pig Irons in Germany. Iron Age, vol. 108, no. 18, Nov. 3, 1921, pp. 1137–1138. Methods of production during war to overcome scarcity of low phosphorus irons; their properties; charcoal iron. Translated from Stahl u. Eisen, June 20, 1921.

K

KEROSENE

Carburation. Carburation of Kerosene and the Action of the Walls (La carburation par le petrole lampant et l'action de paroi), G. Lumet. Memoirs et Compte Rendu des Travaux de la Societe des Ingenieurs Civils de France, vol. 74, no 3 5 6, April-June, 1921, pp. 291–300. Discusses effect of cooling the walls and gives results of tests made, also tables

L

LABOR

Hours of Work. The Eight Hour Law (La Loi des Huit Heures), Léon Repriels. Révue Universelle des Mines, vol. 10, no. 6, Sept. 15, 1921, pp. 651–676. Discusses its provisions and its application, and why Belgium cannot ratify the Washington eight-hour convention.

Organization. The Purpose of the Labor Articles in Automotive Industries, Harry Tipper. Automotive Industries, vol. 45, no. 15, Oct. 13, 1921, pp. 732 733. Points out necessity for studying human side of production activities with a view to preventing trouble rather than waiting for difficulties to arise and then attempting to find a remedy. Production cost depends largely upon human organization

LABOR TURNOVER

Problem. A Common Sense Attack on Turnover, James R. Adams. Indus. Managment, vol. 62, no. 5, Nov. 1921, pp. 298–302, 4 figs. Writer tells what has been done by Studebaker Corp. under present conditions, to make employees appreciate management's problems and to enlist their intelligent coöperation for the common good.

LABORATORIES

Applied Mechanics. A Laboratory of Applied Mechanics (Notice sur le Laboratoire de Mécanique appliquée), J. Boulvin, F. Keelhoff, G. Van Engelen, O. Steels. Annales de l'Association des Ingénieures Sortis des Écoles Spéciales de Gand, vol. 11, 5th Series, 1921, pp. 130–148. Discusses its functions, and equipment for teaching purposes.

Gas. The Industrial Laboratory of the Bourbonnais Co. (Le Laboratoire industriel de la Compagnie du Bourbonnais), J. H. Brodin. Chaleur et Industrie, vol. 2, no. 17, Sept. 1921, pp. 554–560, 4 figs. Discusses development and equipment dedicated to gas interests.

Scientific Industrial Research. A Modern Scientific Industrial Research Laboratory and Its First Results (Un exemple de laboratoire moderne pour recherches de science industrielle; ses premiers résultats), Georges Baume. Révue Générale de l'Electricité, vol. 10, no. 12, Sept. 24, 1921, pp. 396–398. Discusses laboratory of Société de Recherches et Perfectionnements Industriels, founded in 1919 at Puteaux, and how it works.

LATHE TOOLS

Circular Form Tools. Designing Circular Form Tools. Eng. Production, vol. 3, no. 55, Oct. 20, 1921, pp. 370–371, 2 figs. Describes use of practical formulas.

Apron Design. Lathe Aprons, A. Clegg. Eng. Production, vol. 3, no. 55, Oct. 20, 1921, pp. 373–378, 12 figs. Comparison between typical English and American designs.

Economical Operation. Study of Economical Lathe Operation with Special Regard to the Cutting Pressure (Ein Beitrag zur Erforschung der Wirtschaftlichkeits an Drehbänken unter besonderer Berücksichtigung des Schnittdruckes), Herbert Sack. Betrieb, vol. 3, no. 25, Sept. 15, 1921, pp. 800–813, 21 figs. Investigation of effective power and its dependence on feed and depth of cut in connection with detachment of chip. A diagram is developed from which the cutting speed for cross-section of every chip can be obtained.

Feed Reverse Mechanisms. The Design of Feed Reverse Mechanisms for Lathes, A. Clegg. Machinery (Lond.), vol. 19, no. 472, Oct. 13, 1921, pp. 34–39, 13 figs. Discusses the tumbler, fixed center, bevel, and planetary or epicyclic gears, and their advantages and disadvantages.

Headstock Design. Improved Lathe Headstock Details and their Jigs, Hubert Bentley. Eng. & Indus. Management, vol. 6, no. 15, Oct. 13, 1921, pp. 398–399, 4 figs. Describes very simple and successful type of spring-locking bolt and jig employed to ensure accuracy in drilling of locking bolt holes in both cone and gear wheel.

"Non-Stop" Methods. Devices for Repetition Work. Eng. Production, vol. 3, no. 56, Oct. 27, 1921, pp. 392–393, 4 figs. Describes certain non-stop methods, by means of which lathes or machines are kept running.

Oerlikon Works, Switzerland. Recent Machine-Tool Developments. Engineering, vol. 112, no. 2915, Nov. 11, 1921, pp. 652–656, 23 figs. Describes new lathes made by Swiss Machine-Tool Works, Oerlikon, Two designs are built, one with three-stepped belt cone pulley drive, and one with single-pulley, and all-geared head.

Turret. Production Work in the Locomotive Shop. Machy. (N. Y.), vol. 28, no. 3, Nov. 1921, pp. 228–230, 3 figs. Application of the Bullard vertical turret lathe.

Turret and High-Speed Lathes (Revolverdrehbank und Schnelldrehbank), R. Ende. Betrieb, vol. 3 no. 25, Sept. 15, 1921, pp. 789 797, 8 figs. Points out as an example that round parts can be as accurately machined on a turret as on a high speed lathe, without employment of skilled labor required for latter machine. Thus initial increased cost of installation is often made up within a year's time.

LIFTING MAGNETS

German Type. Lifting Magnets (Lasthebemagnete). Glasers Annalen, vol. 89, no. 5, Sept. 1, 1921, pp. 51 56, 8 figs. Describes construction, handling and uses of lifting magnets, with special reference to the Demag (Duisburg, Germany) type.

LIGHTING

Exterior and Interior. Improved Practices in Exterior and Interior Illumination. Elec. World, vol. 78, no. 20, Nov. 12, 1921, pp 971 974, 8 figs. Broadening applications of modern equipment yielding greater service to industry and homes.

Factory. Better Illumination Cuts Production Costs, WardHarrison, Orville F. Haas and Fred W. Dopke, Elec. World, vol. 78, no. 16, Oct. 15, 1921, pp. 763 764, 2 figs. Test data show increase in production of 12.2 per cent due to installation of modern lighting system. Tests made by Dover Mfg. Co., Dover, Ohio.

LIGNITE

Water-Soluble Ash. Importance of Water-Soluble Ash in the Evaluation of Lignite (Wichtigkeit der wasserlöslichen Asche bei der Verwertung der Braunkohle), Th. Limberg. Feuerungstechnik, vol. 9, no. 22, Aug. 15, 1921, pp. 205–207. Points out importance of analysis of composition of ash, and discusses influence of water-soluble ash on the different products of lignite.

LOCOMOBILES

German Type. The Overtype Steam Unit, H. Keay Pratt. Mech. World, vol. 69, no. 1782, Feb. 25, 1921, pp. 141–143, 1 fig. Discusses development of locomobile by R. Wolf of Magdeburg, giving 1 b.hp. per lb. of coal in special trials. Advantages and details of operation.

LOCOMOTIVE BOILERS

Fire Tubes, Mounting. Mounting and Fixing Fire Tubes in Locomotive Boilers (Le montage et la fixation des tubes a fumée dans les chaudières de locomotives), H. Gallon. La Technique Moderne, vol. 13, no. 2, Feb. 1921, pp. 59–62, 12 figs. Describes new automatic apparatus for the purpose.

LOCOMOTIVES

Boosters. The Locomotive Booster As an Operating Factor. Ry. Rev., vol. 69, no. 15, Oct. 8, 1921, pp. 461–469, 16 figs. Results of tests made with five new Pacific and one Mikado types of locomotives fitted with boosters. Operating characteristics.

Economic Use of Steam. On the Question of the Economic Production and Use of Steam on Locomotives, Maurice Lacoin. Bulletin International Ry. Assn., vol. 3, no. 9, Sept. 1921, pp. 1157–1204, 35 figs. Discusses steam superheating and compounding, packings, valves, feedwater heating water-tube boilers, scale, combustion control, etc., Appendixes.

Economical Design. Avoidable Waste in Locomotive Operation as Affected by Design, James Partington. Mech. Eng., vol. 43, no. 11, Nov. 1921, pp. 729–730. Points out that best way to overcome waste is to design locomotive so that it will fulfill efficiency requirements of (1) a drawbar horsepower for minimum amount of fuel, (2) for minimum amount of weight of locomotive and tender, and (3) for minimum cost of repairs, and shows how these are secured. (Abstract.)

Feedwater Heating. Feed Water Heating on the London & North Western Railway. Ry. Gaz., vol. 35, no. 16, Oct. 14, 1921, pp. 572–574, 2 figs. Details of latest application of Weir feedwater heating system and pump to "George the Fifth" class of express locomotive.

Floating Bushings. The Development of Floating Bushings. Ry. Rev., vol. 69, no. 17, Oct. 22, 1921, pp. 535–538, 5 figs. Describes early development, and recent application to new locomotives built by Am. Locomotive Co.

Mallet. Virginian Mallet Locomotives. Ry. Jl., vol. 27, no. 10, Oct. 1921, pp. 12–13, 1 fig. Tractive power 147,200 lb. working compound and 176,600 lb. working simple; 2-10-10-2 type. Comparison with 2-8-8-2 type.

Mexican Railways. New Power for Rehabilitation of Mexican Railways. Ry. Rev., vol. 69, no. 18, Oct. 29, 1921, pp. 578–580, 5 figs. Baldwin builds nearly 100 locomotives comprising five distinct type for service on heavy grades. See also Ry. Age, vol. 71, no. 20, Nov. 1912, 21, pp. 937–939.

Northern Pacific. New Locomotives for the Northern Pacific. Ry. Age, vol. 71, no. 17, Oct. 22, 1921, pp. 767–769, 3 figs. Pacific type for heavy fast service. Mikados, mallets and switchers follow lines of earlier designs.

Operation. Traveling Engineers Present Valuable Reports. Ry. & Locomotive Eng., vol. 31, no. 10, Oct. 1921, pp. 265–271. Discusses operation and maintenance of oil-burning locomotives, self-adjusting wedges, feedwater heaters, devices for increasing tractive power, and operating stoker-fired locomotives. Report of Executive Committee.

Paulista Railway, Brazil. Electric Motive Power for Paulista Railway. Ry. Age, vol. 71, no. 16, Oct. 15, 1921, pp. 721–722, 3 figs. Describes electric freight and passenger locomotives for Brazil; tractive efforts at 25 per cent adhesion 58,500 lb. and 51,000 lb. respectively.

Thermic Siphons. The Installation and Operation of Thermic Syphons. Boiler Maker, vol. 21, no. 10

Oct. 1921, pp. 273–277, 12 figs. Discusses application to locomotives as an efficiency-promoting device.

Valve Gear. Poppet Valve Gear for Steam Locomotives (Weiteres uber die Ventilsteuerung bei Dampflokomotiven), H. Wittfeld. Zeit. des Vereines deutscher Ingenieure, vol. 65, no. 44, Oct. 29, 1921, pp. 1141–1142, 10 figs. Supplementary to article in same journal (no. 24, p. 623), a special type of Lentz gear is described and compared with an older type.

LUBRICATION

Tests on Steam and Gasoline Engines. Comparative Lubrication Engineering. Sci. Lubrication, vol. 1, no. 9, Sept. 1921, pp. 18–21. Describes test on small-power Corliss engine, and on a Continental motor, giving some interesting dilution data.

LUBRICATING OILS

Castor and Mineral-Oil Mixture. Tests of Castor Oil and Mineral-Oil Mixtures on Gnome Rotary Engine, O. J. May and Howard Cooper. Sci. Lubrication, vol. 1, no. 9, Sept. 1921, pp. 10–14, 6 figs. U. S. Army Service report discussing method and results of tests made.

M

MACHINE CONSTRUCTION

Allowances. Determination of the Required Allowance Dimensions for Different Constructions (Feststellung der erforderlichen Passmasse fur die verschiedenen Erzeugnisse), W. Kühn. Betrieb, vol. 3, no. 26, Sept. 25, 1921, pp. 406–411, 8 figs. Explains when limit gages should be used and how selection of allowance dimensions for a given construction piece should be made.

Record of Materials. Record of Materials Used in Machine Construction. Machinery (Lond.), vol. 19, no. 471, Oct. 6, 1921, pp. 1–3, 4 figs. Gives details of a "commodity book" in which are recorded all materials and standard parts used by the firm, these records are kept up-to-date. Various advantages are claimed for this book.

MACHINE SHOPS

English. Famous British Works. Eng. Production, vol. 3, nos. 55, 56 and 57, Oct. 20, 27 and Nov. 3, 1921, pp. 362–363, 4 figs., 386–388, 4 figs., and 410–411, 2 figs. Oct. 20: Worcester works of Heenan & Froude, Ltd., for manufacture of Froude dynamometers, Heenan air filters, oil and water coolers, refuse destructors, and refrigerating machinery. Oct. 27: Works of Marshall, Sons & Co., Ltd., Gainsborough, Lincolnshire, for manufacture of engines, boilers and machines. Nov. 3: Works of John Fowler & Co., Ltd., Leeds, for manufacture of steam plows, road-transport and heavy-haulage engines, traction engines, etc.

The Wellman-Smith-Owen Engineering Works at Darlaston. Iron & Coal Trades Rev., vol. 103, no. 2798, Oct. 14, 1921, pp. 545–546, 18 figs. on pp. 547–550. Describes machine, fitting and erecting, and pattern shops, laboratory, welfare section, etc.

Layout. Building Machine Tools in a New Plant, F. L. Prentiss. Iron Age, vol. 108, no. 17, Oct. 27, 1921, pp. 1070–1075, 16 figs. Arrangement, transportation system, routing of material and lighting are features of Colburn Machine Tool Co., Cleveland, Ohio.

Factory Lay-out as an Aid in Reducing Costs. Machy. (N. Y.), vol. 28, no. 3, Nov. 1921, pp. 182–185, 8 figs. Describes new plant of Colburn Machine Tool Co., Cleveland, Ohio, laid out with view to economy in manufacturing.

A Machine Tool Shop of Unusual Construction, Fred H. Colvin. Am. Mach., vol. 55, no. 17, Oct. 27, 1921, pp. 668–670, 8 figs. Description of Colburn Machine Tool Co., Cleveland, Ohio.

Steam Turbine. New Works of the Compagnie Électro-Mécanique at Bourget (Seine) [La nouvelle usine de la Cie. Électro-Mécanique au Bourget (Seine)], Ch. Dantin. Le Génie Civil, vol. 78, no. 26, June 25, 1921, pp. 541–545, 8 figs. Describes constructional details of works, all reinforced concrete.

MACHINE-TOOL INDUSTRY

Orient as Market. The Orient As a Machine-Tool Market, W. H. Rastall. Am. Mach., vol 55, no. 18, Nov. 3, 1921, pp. 730–5. Data on pre-war growth of foreign business and growth since 1913; foreign markets other than European. How to sell machinery in Asia. Address before Machine Tool Builders.

MACHINERY

Dismantling. Valuable Hints on the Dismantling of Machinery. Can. Machy., vol. 26, no. 15, Oct. 13, 1921, pp. 29–32, 8 figs. Discusses separation of rusted parts, seized parts, forcing methods, and bolt action.

Perforated-Record Control. The Control of Machines by Perforated Records, Emanuel Scheyer. Am. Mach., vol 55, no. 19, Nov. 10, 1921, pp. 743–747, 8 figs. Principles of pneumatic and electric control of machinery. Difficulties of automatic control. Machines controlled by paper records.

Power Consumption. Determination of the Power Consumption of Machinery (Bestimmung des Kraftbedarfes von Arbeitsmaschinen). Elektrotechnischer Anzeiger, vol 38, nos. 149, 150, 151, 152 and 153. Sept. 20, 21, 24 and 27, 1921, pp. 1065–1066, 1073–1074, 1079–1080, 1087–1088 and 1095–1096. 11 figs. Notes on numerical determination of power consumption, determination by comparison with machines of same construction type, but different output; determination through measurement.

MANGANESE STEEL

Castings, Grinding. Grinding Manganese Steel Castings, F. B. Jacobs. Foundry, vol. 49, no. 19, Oct. 1, 1921, pp. 767–770, 8 figs. Frogs and switches produced from accurate patterns and carefully molded. Ground because too hard to machine. Annealed before grinding. Wheels are coarse grit in hard grades.

MARINE STEAM TURBINES

S.S. Giulio Cesare. The Machinery of the Four-Screw Geared Turbine S.S. "Giulio Cesare." Engineering, vol. 112, no. 2915, Nov. 11, 1921, pp. 662–664, 18 figs. partly on supp. plate and p. 666. Constructed by Wallsend Slipway and Eng. Co. Ltd.

MATERIALS

Testing. Testing Materials, T. W. MacAlpine. Eng. & Indus. Management, vol. 6, no. 18, Nov. 3, 1921, pp. 498–499. Plea is advanced for formation of a British national testing organization.

MEASURING MACHINES

Internal Diameters. A Machine for the Measurement of Internal Diameters, G. A. Tomlinson. Engineering, vol. 112, no. 2912, Oct. 21, 1921, pp. 558–560, 6 figs. Describes method and machine developed at Nat. Physical Laboratory, Teddington, England, which is said to give high accuracy and allow inside diameter to be explored to any extent necessary.

METALLOGRAPHY

Foundries. Applications of Metallography in Iron, Steel and Malleable Foundries (Anwendungen der Metallographie in der Eisen-, Stahl- und Tempergiesserei), Rudolf Stotz. Giesserei-Zeitung, vol. 18, nos. 24, 25 and 27, Sept. 20, 27 and Oct. 11, 1921, pp. 325–328, 341–344 and 370–372, 43 figs. Notes on microscopic investigation of iron castings. Paper read before Assa. German Foundrymen.

Microscopic Examinations. Metallography—The Microscopic Study of the Structure of Metals, Henry S. Rawdon. Am. Mach., vol. 55, no. 17, Oct. 27, 1921, pp. 659–664, 29 figs. Value of metallurgical science in industry; uses of the microscope. Study of metallic structures. Results of microscopic examinations.

Optics of. The Optics of Metallography, W. I. Patterson. Trans. Am. Soc. for Steel Treating, vol. 2, no. 2, Nov. 1921, pp. 108–132, 36 figs. Deals with important optical parts of microscopes.

METALS

Cold Work, Effect of. Strengthening Metals by Cold-Work, E. Heyn. Chem. & Met. Eng., vol. 25, no. 16, Oct. 19, 1921, pp. 735–736, 2 figs. Explains nature of changes in cold worked metal, elastic and plastic deformation, etc. From Metall und Erz, 1918, Nos. 22 and 23.

Protective Coatings. Metal Coatings as Protection Against Corrosion (Metalüberzüge als Rostschutzmittel), Werner Lange. Zeit. für Metallkunde, vol. 13, no. 9, June 1921, pp. 267–275, 36 figs. Discusses protective coatings of lead, tin and aluminum.

Refinement Tests. Refinement Tests with German Metals (Veredelungsversuche mit inlandischen Metallen), H. Hanszel. Zeit. für Metallkunde, vol. 13, no. 10, July 1921, pp. 319–329, 1 fig. Deals with aluminum, mild steel, cast iron and electron, and discusses methods for testing of metals and alloys.

Rolling. Metal Rolling (Le Laminage), Sigma. La Métallurgie, vol. 53, no. 40, Oct. 6, 1921, pp. 1881–1887. Discusses longitudinal or parrallel rolling; cross or circular rolling, i.e., reeling; and helicoidal or oblique rolling, as for Mannesmann tubes.

Structural Properties. Structural Properties of Metals and Alloys, R. W. Woodward. Am. Mach.; vol. 55, nos. 15 and 16, Oct. 13 and 20, 1921, pp. 596–599 and 636–638, 2 figs. Applicability of metals; factors of strength and elasticity; compression; ductile and brittle materials; fatigue; thermal, magnetic and optical properties; corrosion.

METRIC SYSTEM

Arguments Pro and Con. The Metric System of Weights and Measures, David A. Mulitor. Jl. Eng. Inst. Can., vol. 4, no. 11, Nov. 1921, pp. 569–572. Advantages of system, legal problems, transition steps.

Metric versus English System. Eng. & Contracting, vol. 56, no. 18, Nov. 2, 1921, pp. 426–427. Summarizes points in favor and opposed to metric bill. Reprinted from Lefax.

MILLING CUTTERS

Formed. Formed Milling Cutters, George H. Strain. Machinery (Lond.), vol. 19, no. 474, Oct. 27, 1921, pp. 109–112, 18 figs. Factors in design which eliminate waste of driving power; cutting angles, rake and clearance of circular tools; standards for convex and concave formed milling cuttings.

MILLING MACHINES

Heavy Vertical. Investigation of a Heavy Vertical Milling Machine (Untersuchung einer schweren Senkrechtfräsmaschine), Willi Mitan. Zeit. des Vereines deutscher Ingenieure, vol. 65, no. 43, Oct. 22, 1921, pp. 1116–1118, 13 figs. Construction and operation of new machine by Fritz Werner Corp. Berlin-Marienfelde, for unwieldy workpieces. Calculation of feeds and speeds. Performance tests.

Rotary. Reducing Costs by Rotary Milling. Machy. (N. Y.), vol. 28, no. 3, Nov. 1921, pp. 202–205, 10 figs. Examples of work advantageously handled on Becker vertical rotary milling machines.

MOLDING MACHINES

Modern. Modern Molding Machines (Neuere Formmaschinen), U. Lohse. Giesserei-Zeitung, vol. 18, nos. 23, 24 and 25, Sept. 13, 20 and 27, 1921, pp. 308–311, 331–335 and 344–348, 20 figs. Construction development during recent years. Deals with hand and power-molding machines, pattern machines with lifting carriage, stripping-plate and roll-over machines, etc.

MONEL METAL

Welding. Monel Metal Welding, Michael Dzamba. Welding Engr., vol. 6, no. 10, Oct. 1921, pp. 41–42. Discusses welding generally, also welding of rods, sheets and castings, and soldering.

MOTOR PLOWS

Engines. The 45/60-Hp. B.M.W. Motor-Plow Engine (Der 45/60 B.M.W. Pflugmotor), Otto Schwager. Oel- u. Gasmaschine, vol. 18, nos. 6 and 10, June and Oct., 1921, pp. 97–104 and 164–165, 7 figs. Details of engine built by the Bavarian Motor Works Corp., Munich, based on their experiences in construction of aeroplane engines. Test results with described engine.

MOTOR TRUCKS

Future. The Motor Truck of the Future, Rollin W. Hutchinson. Indus. Management, vol. 62, no. 5, Nov. 1921, pp. 257–261, 4 figs. What permanent highways, pneumatic tires and ferro-steel will do in revolutionizing motor-truck engineering.

German. German Motor Trucks and Tractors (Der Kraftwagen als Nutzfahrzeug). Allgemeine Automobil-Zeitung, vol. 22, nos. 29, 30 and 31, July 16, 23 and 30, 1921, pp. 23–26, 26–30 and 21–26, 32 figs. Details of various types, including delivery trucks, tippers, timber-hauling trucks, hearses, street sprinklers, hook-and-ladder cars, omnibuses, etc.

N

NICKEL ALLOYS

Nickel-Aluminum-Copper. The Properties of Some Nickel-Aluminium-Copper Alloys, A. A. Read and R. H. Greaves. Metal Industry (Lond.), vol. 19, no. 13, Sept. 23, 1921, pp. 232–239, 23 figs. Discusses preparation; rolling and machining; tensile tests; properties of cast, cold-rolled and heat-treated alloys, etc. Paper read before Inst. of Metals.

NICKEL METALLURGY

Rolling. Rolling Pure Nickel, A. E. Surface. Sci. Am., vol. 125-A, no. 17, Nov. 1921, p. 34, 3 figs. Describes rolling of 99-per cent pure nickel into the various shapes into which mild steel is rolled, according to method developed by Charles T. Hennig and carried out at plant at Hyde, Pa.

NUTS

Acme Thread. Making an Accurate Acme Thread Nut, B. M. W. Hanson. Machy. (N. Y.), vol. 28, no. 3, Nov. 1921, pp. 197–199, 4 figs. Notes on difficulty of obtaining proper contact between screw and nut; use of roughing and finishing taps; lubrication when tapping; holding an Acme tap in a turret lathe.

O

OIL ENGINES

Marine. Oil Fuel Burning Installation on S.S. "Paris" (Installation de la chauffe au pétrole sur le paquebot "Paris"). Bulletin Technique du Bureau Véritas, vol. 3, no. 8, August 1921, pp. 181–185, 4 figs. (In English on pp. 186–188.) Discusses storage, piping, pumps, burners and operation, and gives test data.

Still. The Still Engine. Mar. Engr. & Naval Architect, vol. 44, no. 528, Sept. 1921, pp. 36–40, 4 figs. Describes engine which may be two-stroke or four-stroke type; burns gas, petrol or oil. Advantages, starting, overload, efficiency, etc.

OIL FUEL

Burning. The Burning of Oil Fuel, A. Keens. Mar. Engr. & Naval Architect, vol. 44, no. 529, October 1921, pp. 76–85, 12 figs. Discusses various types of machinery and its arrangement for burning oil fuel. Observations and comments derived from experience.

Combustion. Combustion of Fuel Oil, Percival J. Woolf. Iron & Coal Trades Rev., vol. 103, no. 2797, Oct. 7, 1921, p. 501. Discusses drawbacks of excess of air supplied for rapid combustion, advantages and disadvantages of an additional combustion chamber, and the Sklovsky patent for eliminating excess air. Extract of paper read before Refractory Matls. Section of Ceramic Society.

Handling. Security in Handling Inflammable Liquids Chem. Age (Lond.), vol. 5, no. 119, Sept. 24, 1921, pp. 372–373, 1 fig. Describes Mauclère patent for storage and protection of petrol which also permits distribution either in a continuous flow or in predetermined quantities.

Mexican. The Production and Combustion of Mexican Fuel Oil—VII, J. M. Pettingell and J. R. Carlson. Combustion, vol. 5, no. 5, Nov. 1921, pp. 209–212, 7 figs. Describes use of Mexican oil in various metallurgical furnaces, although sulphur content is high.

Power Uses. The Application of Oil to Power Purposes, Sydney H. North. Trans. Inst. Mar. Engrs., vol. 33, Sept. 1921, pp. 325–331. Shows increase in water evaporated per lb. of oil, and in thermal efficiency of Diesel engines.

OIL STORAGE

Shipyard Plant. Shipyard Bulk Storage Oil and

Paint Plant. Engineering, vol 112 no 2914 Nov 4, 1921, p. 632, 10 figs. partly on p. 634 Describes installation at new yard of Furness Shipbuilding Co., designed with steel storage tanks and automatic measuring pumps for distribution of oils, layout being such as to reduce cost and increase ease of handling.

OILS

Linseed. Air Required in Baking Cores Made With Linseed Oil, A. A. Grubb and U. S. Jamison. Chem & Met Eng vol 25 no 17 Oct 26, 1921, pp 793 795. Results of laboratory and plant experiments on consumption of air and oxygen in baking linseed oil-bound cores together with a review of available data on absorption of oxygen by linseed oil in drying.

P

PARACHUTES

Aeronautical Life Belts. Parachutes. T. Orde Lees. Aviation vol 11, nos 16 and 17, Oct 17 and 24 1921 pp. 451-453 and 485-488, 5 figs. Discusses parachutes in the sense of aeronautical life-belts for pilots and passengers. Lecture before Roy. Aeronautical Soc.

PETROLEUM

Catalytic Oxidation. The Catalytic Oxidation of Petroleum Oils, C. E. Waters. Jl. Indus & Eng. Chem., vol 13, no 10, Oct. 1921, pp 901-903. Discusses briefly relation between oxidation of petroleum oils and formation of deposits in internal-combustion engines to sludging of transformer oils and to deterioration of turbine oils.

PIPE, CAST-IRON

Manufacture. Cast Iron Pipe. The Method of Manufacture and Its Inspection, William R. Conrad. N. E. Water Works Assn. vol 35, no 3 Sept 1921, pp 205-220 and (discussion) pp 220-227, 6 figs. Discusses manufacturing details, including drying, pouring, cleaning and testing.

Standardized. Standardized Cast Iron Pipes. Eng. Production vol 3 no 56, Oct 27, 1921, pp 401-404, 10 figs. Describes methods of Stanton Ironworks Co., Ltd., Nottingham, England, as example of advantages attendant on standardization of foundry products.

PIPE, STEEL

Butt-Welded. Recent Improvements in the Manufacture of Welded Pipe, F. N. Speller. Blast Furnace & Steel Plant, vol. 9, no. 10, Oct. 1921, pp. 580-582. While there have been many improvements in appliances for butt-welding pipe since introduction of this process, the method of finishing has not been materially changed for some time.

Hammer-Welded. A Hammer-Welded Steel Pipe. Iron Age, vol. 108, no. 18, Nov. 3, 1921, pp. 1130-1131, 3 figs.; also Iron Trade Rev., vol. 69, no 18, Nov. 3, 1921, pp. 1148-1151, 7 figs. Product of National Tube Co., Pittsburgh. Steel plates are bent to required shape and overlapping edges are heated and welded under hammer. Hammer-weld process adapted to large sizes of pipe. Protective coating applied.

Hammer-Welded Pipe; Its Manufacture and Use. Eng. & Contracting, vol. 56, no. 19, Nov. 9, 1921, p. 445, 1 fig. Notes on sizes and thickness; manufacturing process; physical properties of material; joints, elements of economy and efficiency. Describes a hammer-weld gas line. (Abstract.) National Bul. No. 13 published by Nat. Tube Co.

Manufacture. Bessemer Plant of Steel & Tube Company, Gilbert L. Lacher. Iron Age, vol. 108, no. 19, Nov 10, 1921, pp. 1199-1205, 11 figs. Latest developments in design and equipment embodied in addition to Mark works, Chicago, for manufacture of pipe.

PISTONS

Aluminum, Machining. Precision Machine Work in the Production of Aluminum Pistons, J. Edward Schipper. Automotive Industries, vol. 45, no. 15, Oct. 13, 1921, pp. 722-725, 15 figs. Methods employed in manufacturing pistons for Essex engine. Special care exercised in machining piston pin hole square with piston axis, and in aligning piston with cylinder bore.

Machining. Machining Hudson Super-Six Pistons. Machy. (N. Y.), vol 28, no 3, Nov. 1921, pp. 225-227, 5 figs. Methods used by Hudson Motor Car Co. in producing pistons with high-production machinery at low cost.

PLATES

Perforated, Stresses in. Increased Stress Caused by Circular Holes in a Plate Under Tension (Ueber die Spannungserhöhung durch kreisförmige Löcher in einem gezogenen Bleche), Th. Pöschl. Zeit. für angewandte Mathematik u. Mechanik, vol. 1, no. 3, June 1921, pp. 174-180, 3 figs. Derivation of formulas for determining increase in stress caused by a number of holes, as for example, rivet holes in a plate.

POWER

Industrial, Analysis of. Analysis of Industrial Power, H. Goodwin. Power, vol. 54, no. 16, Oct. 18, 1921, pp. 584-588, 3 figs. Investigations based on latest census returns from North Atlantic States show more than 76,000 industrial plants, using in aggregate over 9,000,000 hp. of which over 2,000,000 hp. is supplied by steam engines, 600,000 by steam turbines, 540,000 by water power, 279,000 by internal-combustion engines, and remainder purchased power.

POWER GENERATION

Cost Systems. How to Follow Up Power Costs, N. A. Graigue. Indus. Management, vol. 62, no. 5, Nov. 1921, pp. 275-279, 3 figs. Analysis and distribution of operating costs to consumers.

Fuel Economy. Fuel Economy by the Adoption of Scientific Management in Power Generation and Utilization, David Brownlie. Eng. & Indus. Management, vol 6, no 14, 15 and 16, Oct 6, 13 and 20, 1921, pp 393-394 and 396, 421-424 and 433-436, 13 figs. Notes on flue-gas analysis and boiler feedwater meters.

POWER PLANTS

Coal Mine. Mixed-Pressure Turbine Installation with Regenerator Appreciably Decreases Power Costs at Nokomis, C. W. Smith. Coal Age, vol 20, no 19, Nov 10, 1921, pp 753-757, 7 figs. Describes very modern coal-mine power plant at Nokomis mine, Illinois, of Nokomis Coal Co.; capacity 1,300 kw. of which 1,000 kw. is mixed-pressure and 300 kw. high-pressure turbine power.

Design. Developments in Power Station Design—XII, XIII and XIV. Engineer, vol 132, nos. 3432, 3433 and 3435, Oct. 7, 14 and 28, 1921, pp. 361-365, 390-392 and 445-447, 13 figs. Oct. 7: Babcock boilers for utilization of waste heat from coke ovens and blast furnaces. Oct. 14: Halberg-Beth blast-furnace-gas-cleaning plant; Kirke waste-heat boiler with integral economizer; and waste-heat boilers with vertical tubes. Oct. 28: Describes Bonecourt gas-fired boiler unit; Thomson boilers operated with coke-oven gas; Brett drop-forging-furnace waste-heat unit; Babcock & Wilcox furnace for burning saw-mill refuse.

Mine-Mouth. Seward Plant of Penn Public Service Corporation. Power Plant Eng., vol. 25, no. 19, Oct. 1, 1921, pp. 937-947, 17 figs. A mine-mouth power plant supplying industries in Johnstown district. Details of equipment, mechanical and electrical.

Modern Practice. Refinements of Practice in Modern Power Plants, I. L. Kentish-Rankin. Power Plant Eng., vol. 25, no. 20, Oct. 15, 1921, pp. 988-990. Discusses features regarding furnace construction and the overcoming of difficulties with superheater operation.

Superpower. The Performance and Cost of the Superpower System, Arthur R. Wellwood. Power, vol. 54, no. 19, Nov. 8, 1921, pp. 725-730, 10 figs. As result of work of Superpower Survey, certain vital facts concerning performance and cost of superpower system are presented, and conclusions drawn.

POWER TRANSMISSION

Machine Shops. Transmission of Power in Machine Shops, F. A. Pike. Mech. World, vol. 70, no. 1815, Oct. 14, 1921, p. 298, 3 figs. Advocates more direct driving.

PRESSES

Automobile Parts. Presses and Dies used in the Production of Motor-car Body Parts. Machinery (Lond.), vol. 19, no. 475, Nov. 3, 1921, pp. 117-121, 10 figs. Description of tools and machines used by Austin Motor Co., Ltd., Longbridge Works, Birmingham.

PRICES

Stop-Loss, Finding. Finding the "Stop Loss" Price Point, H. R. Boston. Indus. Management, vol. 62, no. 5, Nov. 1921, pp. 266-268. Definite way of estimating how far a price may be cut.

PRODUCER GAS

Qualitative Regulation. Device for the Qualitative Regulation of Producer Gas (Vorrichtung zur qualitativen Regelung von Generatorgas), Robert Nitzschmann. Feuerungstechnik, vol. 9, no. 22, Aug. 15, 1921, pp. 209-211, 2 figs. Discusses basic principles for qualitative regulation and describes arrangement which is said to fulfill required conditions.

PULVERIZED COAL

Advantages and Disadvantages. Firing With Pulverized Coal (Le Chauffage au charbone pulvérisé), P. Frion. Memoirs et Compte Rendu des Travaux de la Société des Ingenieures Civils de France, vol. 74, no. 4-5-6, April-June 1921, pp. 123-172. Report of Commission of Fuel Utilization, appointed by Minister of Pub. Works. Discusses actual developments in use of pulverized coal. Describes installation using it, its advantages and possibilities, and its inconveniences and dangers. See also Révue Universelle des Mines, vol. 11, no. 1, Oct. 1, 1921, pp. 48-56.

Firing With Pulverized Coal (Le Chauffage au charbon pulverisé), Sigma. La Métallurgie, vol. 53, no. 38, Sept. 22, 1921, pp. 1781-1782. Discusses disadvantages and draws conclusions comparing these with advantages. (Concluded.)

Boiler Firing. Burning Powdered Coal and Blast-Furnace Gas at River Rouge, Thomas Wilson. Power, vol. 54, no. 18, Nov. 1, 1921, pp. 664-670, 9 figs. Arrangement and construction of big boilers and their control. Pulverized-coal equipment and layout of gas piping and burners. Performance guarantees and operating force required.

Burning Powdered Coal in Boiler Furnaces, K. Kita. Jl. Inst. Elec. Engrs. of Japan (Denki Gakkwai Zasshi), no. 399, Oct. 1921, pp. 713-740. Author tries to make comparison of combustion of powdered coal with that of ordinary method, and points out important factors to be considered in construction of furnace. Bibliography. (In Japanese.)

PUMPING

Centrifugal and Air-Lift. Modern Pumping. Colliery Guardian, vol. 122, no. 3170, Sept. 30, 1921, pp. 933-934. Paper on "Modern High Speed Centrifugal Pumps" by S. F. Barclay and paper on Experiments in Air Lift Pumping by J. S. Owens. Read before British Assn. See also Eng. & Indus. Management, vol. 6, no. 18, Nov. 3, 1921, pp 503-506.

PUMPS, CENTRIFUGAL

Design and Application. The Centrifugal Pump, S. F. Barclay. Engineering, vol. 112, no. 2914, Nov. 4, 1921, pp 642-644, 8 figs. Notes on mechanical design and application. (Abstract.) Paper read before British Assn.

Manufacture. Manufacturing Centrifugal Pumps. Western Machy. World, vol. 12, no. 10, Oct. 1921, pp. 392-395, 12 figs. Describes machine operations on pump bases, brackets, spiral bodies, impellers, etc.

PUNCHING MACHINES

Efficiency. Increasing the Efficiency of Punching Machines (Zur Frage der Leistungssteigerung bei Lochwerken), Hugo Becker. Betrieb, vol. 3, no. 25, Sept. 15, 1921, pp. 832-838, 16 figs. Comparison of costs of punching work in the plating of a freight steamer with use of a simple punching machine and of a roller table machine shows economy of latter.

R

RADIOMETALLOGRAPHY

Possibilities. X-Ray Photography and Material Testing (Röntgenphotographie und Materialprüfung), R. Schenck. Stahl u. Eisen, vol. 41, no. 41, Oct. 13, 1921, pp. 1441-1449, 24 figs. Discusses nature of Röntgen rays and possibilities for their use in material testing and metallography.

RAILS

Magnetic Surveys. Magnetic Surveys of Railroad Rails. Iron Age, vol. 108, no. 20, Nov. 17, 1921, pp. 1271-1273, 7 figs. Determination of fissures obscured by heavy damage from gagging presses. Improvements being made in section and in straightening.

Second-Hand, Use of. Classification and Distribution of Second Hand Rail for Use in Track. Eng. & Contracting, vol. 56, no. 20, Nov. 16, 1921, pp. 463-464. Notes on supply and demand for used rail; variables to be considered in use of rail; recommended method of assigning and distributing rail.

RAILWAY CONSTRUCTION

Germany. Construction of the Railway Between Tongres and Aix-la-Chapelle (Der Eisenbahnbau Tongern-Aachen), E. Hünerwadel. Schweizerische Bauzeitung, vol. 78, nos. 14, 15 and 17, Oct. 1, 8 and 22, 1921, pp. 163-167, 182-184 and 201-205, 22 figs. Describes section including bridges and tunnels built by Germany between years of 1915 and 1918, said to be one of largest and most important works of engineering carried out during war.

RAILWAY ELECTRIFICATION

Austria. The Electrification of the Austrian Federal Railway (Die Elektrisierung der österreichischen Bundesbahnen), H. Baecker. Glasers Annalen, vol. 89, no. 5, Sept. 1, 1921, pp. 48-51, 1 fig. Notes on projects, hydroelectric and power-transmission plants.

Brazil. The Paulista Railway Electrification, S. B. Cooper. Ry. Rev., vol. 69, no. 16, Oct. 15, 1921, pp. 507-509, 8 figs. Describes Westinghouse equipment recently delivered and conditions making electrification desirable.

Heavy Traction. Electrification Report of the A.E. R.A. Ry. Elec. Engr., vol. 12, no. 10, Oct. 1921, pp. 391-396, 1 fig. Report of Committee of the Am. Elec. Ry. Assn. on heavy electric traction. Compares locomotives and multiple unit-cars. (Abstract.)

Italy. Economic Aspects of Electric Traction in Italy (Aspetti economici della trazione elettrica in Italia), Pietro Lanino. Ingegneria Italiana, vol. 7, no. 170, Sept. 10, 1921, pp. 144-146. Summarizes needs of Italian electrification and gives list of impending constructions.

Electrification Progress on Italian Railways, Giovanni B. Santi. Ry. Elec. Engr., vol. 12, no. 10, Oct. 1921, pp. 371-375, 6 figs. Discusses development of electrification on account of high price of coal and no oil resources. The Valtelline three-phase, 15-cycle, 3000-volt system has been working for 20 years.

Steel Plant. Electrification of the Steel Plant Railroad, R. B. Gerhardt. Blast Furnace & Steel Plant, vol. 9, no. 10, Oct. 1921, pp. 613-617. Discusses savings effected in fuel, repairs, labor, and depreciation; also discusses safety, frogs and switches, etc. (Abstract.) Paper read at Assn. Iron & Steel Elec. Engrs. Convention.

RAILWAY MOTOR CARS

Gasoline. Petrol Rail Motor Cars, Kalka-Simla Railway. Ry. Gaz., vol. 35, no. 15, Oct. 7, 1921, pp. 535-539, 7 figs. Describes car for narrow-gage mountain service in India under severe working conditions, due to steep inclines and many sharp curves. Design includes several noteworthy features particularly gearing and transmission, frame construction, and combination of coupled wheels and radial trucks to give flexibility on curves.

RAILWAY OPERATION

Automatic Train Control. Automatic Safety Apparatus and Automatic Train Control (Appareil automatique de sûreté et de contrôle des trains), Maurice Gouineau. Révue Générale de l'Élec-

tricité, vol. 10, no 12, Sept. 24, 1921, pp. 406–412, 10 figs. Describes Regan system as adapted to French railroads.

Cab Signaling and Automatic Stopping of Trains (La répétition des signaux sur les machines et l'arrêt automatique des trains), J. Netter. La Technique Moderne, vol. 13, no. 3, March 1921, pp. 101–104, 7 figs. Criticism of Regan system recently tested on Paris-Dreux line; comparison with Rodolausse apparatus, systems used by principal French railroads.

Interchange of Rolling Stock. On the Question of Interchange of Rolling Stock, C. W. Crawford. Bulletin International Ry. Assn., vol. 3, no. 9, Sept. 1921, pp. 1275–1321. Discusses the question as it affects United States, Canada and Mexico. Gives summary of their regulations and practices, also answers to questions sent. Appendixes.

Passenger Traffic. Handling Heavy Passenger Traffic at Doncaster. Ry. Gaz., vol. 35, no. 14, Sept. 30, 1921, pp. 493–496 and 507, 4 figs. Describes the special traffic arrangements made by Great Central and Great Northern Railways in connection with the race traffic.

RAILWAY REPAIR SHOPS

Contract Shop, vs. The Cost of Contract vs. Railway Shop Repairs, J. W. Roberts. Ry. Age, vol. 71, no. 16, Oct. 15, 1921, pp. 729–731, 2 figs. Total cost to railroad was 28 per cent greater in its own shop than in a contract shop.

Experimental Scheme. An Experiment in Railroad Repair Work, Fred H. Colvin. Am. Mach., vol. 55, no. 20, Nov. 17, 1921, pp. 807–808. Securing greater interest by local management. Improved machinery and buildings. Describes scheme adopted by Erie R.R. at Hornell, N. Y.

Requirements. The Requirements for a Modern Car Repair Shop, H. H. Dickinson and Paul Schioler. Ry. Age, vol. 71, no. 19, Nov. 5, 1921, pp. 890–893, 3 figs. Type of building, character of tools and general plan for both steel and wood equipment.

RAILWAY SHOPS

American Practice. Railway Machine Shop Practice—III. Machinery (Lond.), vol. 19, no. 473, Oct. 20, 1921, pp. 67–69, 9 figs. Examples of American practice in machining bearing brasses, axle boxes and wedges.

Machine Tools for. Railway Shop Machine Tool Equipment. British Machine Tool Eng., vol. 1, no. 2, September-October 1921, pp. 277–399, 188 figs. A series of articles on railway-shop equipment, including locomotive boiler shop, wheel and axle shop, frame shop, spring shop, grinding shop, general machine shop, capstan and turret lathes, carriage and wagon frames, girder work, etc.

RAILWAY SIGNALING

Alternating-Current. Principles of Alternating Current Signaling, John S. Holliday. Ry. Signal Engr., vol. 14, no. 11, Nov. 1921, pp. 443–445, 9 figs. Explanation of motor and generator motion and transformer action that produces rotation in an induction motor.

Automatic. Road Test of New Automatic Train Control. Ry. Signal Engr., vol. 14, no. 11, Nov. 1921, pp. 431–432, 4 figs. Test conducted on system in which no physical contact is made between apparatus on locomotive and on roadway.

Automatic Block. Proposed Modification of Stop-and-Proceed Rule. Ry. Age, vol. 71, no. 19, Nov. 5, 1921, pp. 867–869, 4 figs. Details of practice on fourteen roads using "tonnage" signals, relaxing the stop-and-proceed rule. See also Ry. Signal Engr., vol. 14, no. 11, Nov. 1921, pp. 429–430.

Automatic Color Light. The Re-Signaling of the Liverpool Overhead Railway. Ry. Gaz., vol. 35, no. 16, Oct. 14, 1921, pp. 571 and 576, 4 figs., partly on p. 570. Describes automatic signaling system on electrically operated railroad, using color light signals only.

Block System. Absolute Permissive Block Signal System, C. A. Dunham. Ry. Signal Engr., vol. 14, no. 11, Nov. 1921, pp. 438–440, 7 figs. Study of single track signaling showing track layout and circuit diagram and explaining operation of trains between sidings. (Abstract.) Paper read before Kansas City Sectional Committee Meeting.

Electric. Principles of Alternating Current Signaling, John S. Holliday. Ry. Signal Engr., vol. 11, no. 10, Oct. 1921, pp. 389–390, 12 figs. Explaining an easy method of constructing vector diagrams and the application to track circuit problems.

Interlocking. Interlocking at a Railway Bridge in England, James Benjamin Ball. Ry. Signal Engr., vol. 14, no. 11, Nov. 1921, pp. 424–428, 7 figs. Interesting signaling features on Keadby Deviation Railway and movable span over Trent river. (Abstract.) Paper read before Inst. Civil Engrs.

One-Lever Route. One-Lever Route Signaling. Ry. Gaz., vol. 35, no. 18, Oct. 28, 1921, pp. 643–648, 9 figs. A new design of power locking frame whereby one lever is used to set up each route, signalman is given a visible indication of all that occurs, conflicting movements are rendered impossible and separate point levers are dispensed with entirely.

Progress, America. Progress of Railroad Signaling in America, H. S. Balliet. Ry. Signal Engr., vol. 14, no. 11, Nov. 1921, pp. 433–437. Detailed history of apparatus and methods used from the days of the smoke blanket to present efficient systems. Paper delivered before N. Y. Signal Sectional Committee.

Tunnel Signals. The Electric Signaling System in the Arlberg Tunnel (Zur Geschichte der elektrischen Fernmeldeeinrichtungen des Arlbergtunnels), L. Kohlfürst. Elektrotechnische Zeit., vol. 42, no. 34, Aug. 25, 1921, pp. 939–943. Describes numerous troubles experienced with system installed in 10.25-km. tunnel through which trains driven by steam locomotives are operated. A telephone cable, which when installed measured 8000 microhms resistance per km. from copper to lead sheath dropped in six years to only 0.2 microhm.

RAILWAY TRACK

Concrete Supports. Concrete Block Track Supports on Italian Railways. Eng. News-Rec., vol. 87, no. 17, Oct. 27, 1921, pp. 689–690, 2 figs. Fixed and rocking blocks placed longitudinally have rail seats at each end. Rockers insure vertical loading.

Maintenance. Distributing Expenditures in Track Maintenance, J. L. Starkie. Ry. Maintenance Engr., vol. 17, no. 11, Nov. 1921, pp. 403–405, 4 figs. Gulf, Colorado & Santa Fe is obtaining increased interest and efficiency by means of new work records.

Advantages of Budget System for Track Work, C. A. Morse. Eng. & Contracting, vol. 56, no. 16, Oct. 19, 1921, pp. 370–372. Points out that there should be a carefully prepared budget made up in fall of year including all probable expenditures of coming year outside of ordinary upkeep of track and roadbed. Apportioning amounts covered by budget. Paper presented before Roadmasters & Maintenance of Way Assn.

Scandinavian Construction. On the Question of the Construction of the Road-Bed and of the Track, K. Ahlberg. Bul. International Ry. Assn., vol. 3, no. 9, Sept. 1921, pp. 1147–1156. Concludes that Scandinavian countries will doubtless increase the load per locomotive axle considerably without changing maximum speeds. Appendix.

Turntables. Twin-Span Turntables on the Chesapeake & Ohio. Ry. Rev., vol. 69, no. 18, Oct. 29, 1921, pp. 563–568, 12 figs. Particulars of design and advantages to be realized in use of this type of turntable. Length 100 ft.; carrying capacity 450 tons; built by Bethlehem Bridge Corp.; used for heavy Mallet type of locomotives.

RAILWAYS

Consolidation. Consolidation of Railroads. Ry. Rev., vol. 69, no. 14, Oct. 1, 1921, pp. 423–437, 29 figs. Proposed consolidation of railroad properties of United States into a limited number of systems. Tentative plan of interstate commerce commision based upon Ripley report.

Shanghai-Nanking. Notes on the Shanghai-Nanking Railway. Ry. Gaz., vol. 35, no. 18, Oct. 28, 1921, pp. 637–638, 3 figs. Describes general characteristics, standard gage, high-capacity rolling stock, train control, train service, buildings, etc.

REFRACTORIES

Fireclays. Effect of Impurities in Fire Clays, C. E. Bales. Brick & Clay Rec., vol. 59, no. 10, Nov. 15, 1921, pp. 723–725. Points out that high-grade fireclays must be akin to kaolin. Explains coloration processes and neutralizing of harmful ingredients.

Furnace Lining. Carborundum Linings for Brass Furnaces, M. L. Hartmann. Can. Foundryman, vol. 12, no. 10, Oct. 1921, pp. 34–35. Explains how carborundum refractories are applied to problems in crucible, tilting or rotary, and reverberatory furnaces, with records of certain installations. Paper read at Foundrymen's Convention.

RIVETED JOINTS

Efficiency. A Criticism of High Efficiency Riveted Joints, John S. Watts. Boiler Maker, vol. 21, no. 10, Oct. 1921, pp. 278–279, 3 figs. Calculations indicate that use of multiple riveted joints does not increase seam efficiencies.

ROLLING MILLS

Bar Mills for Alloy Steel. Adapts Bar Mills to Alloy Steel, J. D. Knox. Iron Trade Rev., vol. 69, no. 20, Nov. 17, 1921, pp. 1275–1281, 12 figs. New 12 and 18-in. merchant units installed by Ohio steelmaker rounds out rolling equipment. Unique guide box prevents scrap loss. Rolls adjusted by set screws. Description of mills.

Chambéry, France. Rolling Mill and Foundry of the Société l'Aluminium Francais at Chambéry (Ateliers de laminage et de fonderie de la Société l'Aluminium français à Chambéry), Marcel Blondin. Révue Générale de l'Électricité, vol. 10, no. 12, Sept. 24, 1921, pp. 401–405, 5 figs. Describes equipment.

Electrically Driven. Some Methods of Obtaining Adjustable Speed With Electrically Driven Mills. K. A. Pauly. Proc. Engrs.' Soc. of Western Pa., vol. 37, no. 3, April 1921, pp. 158–178 and (discussion) 179–188, 19 figs. Discusses rolling mill practice, speed of rolling and systems of speed control.

S

SCIENTIFIC MANAGEMENT

See INDUSTRIAL MANAGEMENT.

SEMI-DIESEL ENGINES

Open-Crankcase. The Open-Fronted Surface Ignition Engine, F. G. Butt-Gow. Trans. Inst. Mar. Engrs., vol. 33, Sept. 1921, pp. 239–269 and (discussion) 270–279, 22 figs. Discusses closed and open engines and compares cost of manufacture, running, overhauling, lubrication, etc. Describes various types of open-crankcase engines.

SHAPERS

Toolroom Work. A New Shaping Machine. Eng. Production, vol. 3, no. 55, Oct. 20, 1921, p. 372, 3 figs. Describes machine introduced by The Butler Machine Tool Co., Ltd., Halifax, designed especially for toolroom work.

SOLDERS

Investigation. Metal Solders (Zur Kenntnis der Metallote), L. Sterner-Rainer. Zeit. für Metallkunde, vol. 13, no. 11, Aug. 1921, pp. 368–379, 6 figs. Deals with tin-lead, aluminum, binary copper-zinc, and silver solders, copper-zinc solders containing tin, and iron, steel and gold solders. Determination of composition, melting point, tensile strength and hardness, based on which valuation of the different solders is given.

SPRINGS

Coil. The Manufacture of Coil Springs, A. W. Allen. Machinery (Lond.), vol. 19, no. 474, Oct. 27, 1921, pp. 85–89, 17 figs. Coiling machines; open coil barrel springs; press operations; eye forming; cutting, eyeing and bowing.

Compression. Nested Steel Compression Springs, T. F. Stacy. Am. Mach., vol. 55, no. 20, Nov. 17, 1921, pp. 795–796, 2 figs. Deals with design of concentric springs so proportioned that all springs are worked to maximum fiber stress.

Design. The Design of Springs, Joseph Kaye Wood. Am. Mach., vol. 55, no. 17, Oct. 27, 1921, pp. 674–677, 10 figs. Control of the "spring criterion." Formulas for leaf springs constrained at one or both ends. Characteristics of coil, spiral and buffer springs.

A General Method for Spring Design, Joseph Kaye Wood. Am. Mach., vol. 55, no. 19, Nov. 10, 1921, pp. 757–762, 3 figs. Types of springs. Economy index and load-deflection rate. General formulas and table of constants. Parallel scale chart. Importance of material index.

STANDARDIZATION

Automobile Industry. Industrial Standardization, Geo. W. Watson. Automobile Engr., vol. 11, no. 155, Oct. 1921, pp. 356–358. Advocates more standardization in British automobile industry, including agricultural tractors, etc. Résumé of presidential address before Instn. of Automobile Engrs.

STEAM

Callendar Equations. The Callendar Equations for Steam, Gerald Stoney. Beama, vol. 9, no. 4, Oct. 1921, pp. 345–350, 3 figs. Abstract of some of the best and easiest ways in which to use these equations, with special reference to steam turbine practice.

Production and Distribution Accounting. Accounting for Steam Production and Distribution, A. R. Smith. Power, vol. 54, no. 17, Oct. 25, 1921, pp. 630–633, 1 fig. Describes two forms of balance sheets and enumerates possible losses which can be detected by their use. Ways and means and advantage of metering boiler outputs.

STEAM-ELECTRIC PLANTS

Diagrammatic Recording in. How Can the Executive Keep in Touch with Plant Economy? C. H. Delany. Jl. Electricity & Western Industry, vol. 47, no. 7, Oct. 1, 1921, pp. 267–268, 4 figs. Diagrammatic method of recording results in operation of a steam electric power plant.

STEAM ENGINES

Uniflow. A 200 hp. Uniflow Steam Engine. Power House, vol. 14, no. 18, Sept. 20, 1921, pp. 21–23, 4 figs. Built by Galloways Ltd., Manchester, Has a novel high-speed valve gear and compression release.

[See also LOCOMOBILES.]

STEAM METERS

Types. Modern Feedwater and Steam Meters (Neuere Speisewasser- und Dampfmesser), W. E. Germer. Zeit. für Dampfkessel u. Maschinenbetrieb, vol. 44, no. 33, Aug. 19, 1921, pp. 259–261, 3 figs. Details of piston disk meter with cylindrical measuring disk; the Woltmann meter for turbine condensate; Venturi meter for water and steam.

STEAM PIPES

Reducing Resistances in. Economies Obtainable by Reducing Resistances in Steam Piping, O. Denecke. Mech. Eng., vol. 43, no. 11, Nov. 1921, pp. 735–738, 2 figs. Discussion of general principles on which design of steam piping in power plants should be based, with comparison of formulas suggested for various elements affecting steam consumption as function of resistances encountered to flow of steam. Translated from Zeit. fur Dampfkessel u. Maschinenbetrieb.

STEAM POWER PLANTS

Modern Design. Modern Steam Power Station Design, Frank S. Clark. Jl. Franklin Inst., vol. 192, no. 4, Oct. 1921, pp. 413–452, 11 figs. Notes on present status of turbine design; economical and mechanical features of station design; operation of plant.

STEAM TURBINES

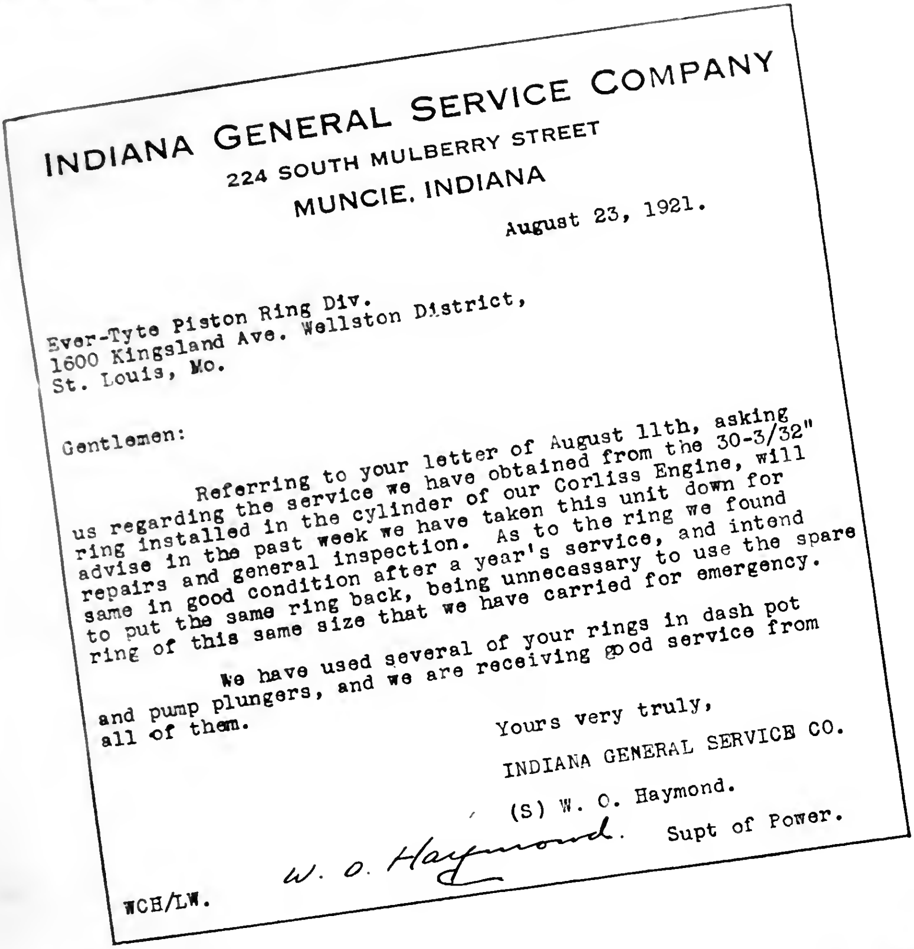
Blading Failures. Low-Pressure Turbine Blading Failures in Destroyers, D. F. Ducey. Engineering, vol. 112, no. 2913 and 2914, Oct. 28 and Nov. 4, 1921, pp. 615–619 and 647–650, 15 figs. Results of chemical analysis of damaged blades, metallographic examination, various heat-treatment, impact-shear and bend tests carried out at experiment station. (Abstract.) Reprinted from Jl. Am. Soc. Nav. Engrs.

STEEL

Artificial Seasoning. Artificial Seasoning of Steels, H. J. French. Am. Mach., vol. 55, no. 19, Nov. 10, 1921, pp. 768–771. Review of available data on length changes and spontaneous generation of heat in hardened steels. Results of preliminary experiments on artificial seasoning. Printed by permission of Bur. of Standards.

Automobile Gear. Investigation of Tooth Wear

It's what the USER says that counts



INDIANA GENERAL SERVICE COMPANY
224 SOUTH MULBERRY STREET
MUNCIE, INDIANA

August 23, 1921.

Ever-Tyte Piston Ring Div.
1600 Kingsland Ave. Wellston District,
St. Louis, Mo.

Gentlemen:

Referring to your letter of August 11th, asking us regarding the service we have obtained from the 30-3/32" ring installed in the cylinder of our Corliss Engine, will advise in the past week we have taken this unit down for repairs and general inspection. As to the ring we found same in good condition after a year's service, and intend to put the same ring back, being unnecessary to use the spare ring of this same size that we have carried for emergency.

We have used several of your rings in dash pot and pump plungers, and we are receiving good service from all of them.

Yours very truly,
INDIANA GENERAL SERVICE CO.
(S) W. O. Haymond.
W. O. Haymond. Supt of Power.

WCH/LW.

Less Fuel
Less Oil
Longer Life
Higher Efficiency

ENGINEERING INDEX (Continued)

With Automobile Gear Steels, E. R. Ross. Automotive Industries, vol. 45, no. 18, Nov. 3, 1921, pp. 865 869 10 figs. Steel with minimum of 0 45 carbon that is capable of treatment giving a scleroscope hardness of 75 or over is recommended for oil treating. Specification limits should be close enough to insure uniform results from a standard heat treatment.

Bar, Weight of. Estimating the Weight of Bar Steel, Hyman Levine. Machy. (N. Y.), vol. 28, no. 3, Nov. 1921, p. 190. Formulas for calculating approximate weights of various sections and lengths of steel.

Cast, Carbonizing Parts. The Carbonizing of Cast Steel Parts, William G. Conner. Trans. Am. Soc. for Steel Treating, vol. 2, no. 2, Nov. 1921, pp. 148-149. Writer finds that all parts or pieces should be cooled in pots to atmospheric temperature.

Cast, Impact Tests on. Study Impact Tests on Cast Steel, F. C. Langenberg. Iron Trade Rev., vol. 69, no. 18, Nov. 3, 1921, pp. 1145–1147 and 1151, 6 figs. Results of investigations on cast steels of varied compositions and heat treatments. Higher shock strength is shown to be obtained from low phosphorus material.

Crystalline Structure. Crystalline Structure of Steel (Stålets kristallbyggnad), Arne Westgren. Jernkontorets Annaler, vol. 105, no. 10, 1921, pp. 401–430, 8 figs. Discusses theory, methods of testing, structure of allotropic modifications of iron, structure of hardened steel, etc.

Hardness Formulas. Determines Hardness Formulas, E. J. Janitzky. Iron Trade Rev., vol. 69, no. 17, Oct. 27, 1921, pp. 1079–1081, 3 figs. Investigation conducted on steel specimens shows that Brinell hardness can be computed by use of mathematical formulas. Outline of method for deriving formula. (Abstract.) Paper presented before Am. Soc. for Steel Treating.

Impact Properties. Impact Properties of Various Steels, F. C. Langenberg. Chem. & Met. Eng., vol. 25, no. 20, Nov. 16, 1921, pp. 910–912, 5 figs. Cylinders of steel, centrifugal cast, were sectioned and tested, a set of steel bars, with increasing carbon content, and some steel casting were tested after various heat-treatments; comparison of impact for forged and cast steels.

Liquid, Surface of. The Surface of Liquid Steel, Cosmo Johns. Engineering, vol. 112, no. 2913, Oct. 28, 1921, p. 619. Supplementary to previous papers by author on appearance of liquid steel as it flows from the launder of an acid open-hearth furnace, and evidence of existence of vapor of iron or steel. Paper read before British Assn.

Nitrogen in Carburized. Nitrogen in Carburized Steels, W. E. Ruder and G. E. Brophy. Chem. & Met. Eng., vol 25, no. 19, Nov. 9, 1921, pp. 867–871, 7 figs. Describes micrographic methods for detection of nitrogen compounds.

Properties. The Properties of Steel. Eng. Production, vol. 3, no. 57, Nov. 3, 1921, pp. 417–418, 1 fig. Notes on influence of various elements.

Stainless. Stainless Steel for Turbines. Electrician, vol. 87, no. 2267, Oct. 28, 1921, pp. 540-541, 5 figs. Examination after 3471 hours run showed that stainless steel blades, polished and unpolished, were practically untouched. See also Iron & Coal Trades Rev., vol. 103, no. 2800, Oct. 28, 1921, pp. 626–627, 8 figs., partly on p. 628.

Stainless Steel in Engineering. Eng. & Indus. Management, vol. 6, no. 17, Oct. 27, 1921, pp. 466-467, 2 figs. Describes demonstration at Thos. Firth's & Sons, Sheffield, England, showing behavior of turbine blades, made from stainless steel, under working conditions. See also Eng. Production, vol. 3, no. 56, Oct. 27, 1921, p. 405, 2 figs.; Engineering, vol. 112, no 2913, Oct. 28, 1921, pp. 592 594, 7 figs.; and Engineer, vol. 132, no. 3435, Oct. 28, 1921, pp. 447 450, 7 figs.

[See also ALLOY STEELS; CHROMIUM STEEL; MANGANESE STEEL; URANIUM STEEL.]

STEEL CASTINGS

Heat Treatment. Heat Treatment Improves Castings, Martin M. Rock. Foundry, vol. 49, no. 20, Oct. 15, 1921, pp 797 799. Tensile tests of unannealed, air cooled and water quenched steel castings do not disclose marked difference in strength but impact tests show water-quenched product excels others.

Welding. The Welding of Steel Castings (Schweissen von Stahlformguss), L. Treuheit. Stahl u. Eisen, vol. 41, no. 39, Sept. 29, 1921, pp. 1361 1366, 21 figs. Notes on different processes with special consideration of electric arc and autogenous welding. It is concluded that for steel castings oxygen-acetylene and fire welding are best processes, and should be used exclusively for highly stressed castings. (Abstract.) Paper before Assn. German Foundrymen.

STEEL, HEAT TREATMENT OF

Hardening. Discussion of the Hardening of Steel and Other Alloys, Oscar E. Harder. Trans. Am. Soc. for Steel Treating, vol 2, no. 2, Nov. 1921, pp. 139 147, 1 fig. With particular emphasis on important part played by solution and precipitation.

Hardness Variation. Hardness Variations in Heat-Treated Steel, Carle R. Hayward Chem. & Met. Eng., vol. 25, no. 15, Oct. 12, 1921, pp. 695 696. Gives some tables of figures for shore center and half-way tests showing greater hardness in center.

Influence of Mass. A Contribution to the Problem of the Influence of Mass in Heat Treatment, E. J. Janitzky. Trans. Am Soc. for Steel Treating, vol. 2, no. 1, Oct. 1921, pp. 55 62, 3 figs. Writer seeks to show that law which relation of mass has to physical properties exists and can be determined mathematically.

Quenching. Efficiency of Various Quenching Mediums With Their Practice and Applications, James B Morey. Trans. Am. Soc. for Steel Treating, vol 2, no. 1, Oct. 1921, pp 63–69, 4 figs. Discusses effect of brine, oil, sperm, lard, sea or salt water.

Tempering. Notes on Tempering (Remarques sur la trempe), L. Grenet. La Technique Moderne, vol. 13, no. 3, March 1921, pp. 104 111, 2 figs. Criticism of Dejean's article dealing with factors affecting tempering, mechanics of tempering, tempering iron and various iron and steel alloys etc. Close of discussion by P. Dejean.

STEEL, HIGH-SPEED

Electric Tool. Features of Electric Tool Steel Practice, W. J. and S. Stuart Green. Iron Age, vol 108, no. 17, Oct. 27, 1921, pp. 1061–1064, 3 figs. Points out that standardized shop practice is necessary. Large ingots are recommended. Top pouring preferred for tool steel.

Ingots, Heat Treatment of. The Heat Treatment of Heavy Ingots of High-Speed Tool Steel (Beitrag zur Frage der Warmformgebung schwerer Blöcke aus Schnellarheitsstahl), W. Oertel. Stahl u. Eisen, vol. 41, no. 40, Oct. 6, 1921. pp. 1413–1416, 8 figs. The formation of cracks with forging of high-speed steel ingots is attributed to presence of coarse carbide concentrations, whereas observed disintegration of a forging in a circular or core part is caused by phenomena in connection with forging in angle saddle. Explains how this disintegration can be prevented.

Treatment. How to Make the Most out of High Speed Steel, A. J. Wilson. Can. Machy., vol. 26, no. 13, Sept. 29, 1921, pp. 35–36. Steel must be heated uniformly. Tools should not be hardened direct from forging operation. Should be annealed.

Tungsten Content, Effect of. Effect of Tungsten Content on the Specific Gravity of High Speed Steel, Arthur S. Townsend. Trans. Am. Soc. for Steel Treating, vol. 2, no. 2, Nov. 1921, pp. 133–138. Observations made in writer's laboratory tend to establish general rule for annealed steels that the higher the tungsten content the higher the specific gravity.

STEEL MANUFACTURE

Enameled Steel. Enameled Steel Manufacture, Chester H. Jones. Chem. & Met. Eng., vol. 25, no. 19, Nov. 9, 1921, pp. 883–886, 9 figs. Development of glass-lined steel containers; fabricating and finishing the steel; mixing and firing the enamel.

STEEL WORKS

Electrical Development in. Electrical Development in Steel Mills, R. B. Gerhardt. Iron Age, vol. 108, no. 18, Nov. 3, 1921, pp. 1135–1136. Report of progress during past year. Advance in control equipment.

French, Rebuilding. French Modernize in Rebuilding, L. Guillet. Iron Trade Rev., vol. 69, no. 18, Nov. 3, 1921, pp. 1152-1154. Better equipment than was used before war installed in iron and steel works. Products of American engineering skill used in some plant. Résumé of restoration. (Abstract.) Paper before British Iron & Steel Inst.

Scotland. The Valuation of Steel Works in Scotland. Colliery Guardian, vol. 122, no. 3169, Sept. 23, 1921, pp. 870-871. Evidence given in connection with reassessment.

STELLITE

Use for Cutting Tools. Stellite and Its Use for Cutting Tools (Le "Stellite" et son emploi pour les outils de tour). L'Ouvrier Moderne, vol. 4, no. 6, Sept. 1921, pp. 227 230, 26 figs. Properties of stellite, degrees of hardness, operating tools, etc.

STOKERS

Elvin Mechanical. Distinctive Features of the Elvin Mechanical Stoker. Ry. & Locomotive Eng., vol. 34, no. 10, Oct. 1921, pp. 259-264, 10 figs. Details of its construction and operation, and improvements made without changing fundamental principles of its design. Applied to Mallet locomotives.

Pluto. The Pluto Stoker and Its Development in the Last Decade (Der Pluto-Rost und seine Entwicklung im letzten Jahrzehnt), H. Pradel. Zeit. fur Dampfkessel u. Maschinenbetrieb, vol. 44, no. 32, Aug. 12, 1921, pp 249 251, 6 figs. Describes improvements since 1911 in forced draft traveling step grate manufactured by Pluto Grate Co , Weiss & Meurs, Ltd., Berlin.

T

TERMINALS, LOCOMOTIVE

Oklahoma City. M. K. & T. Improves Its Facilities at Oklahoma City. Ry. Age, vol. 71, no. 16, Oct. 15, 1921, pp. 713-716, 7 figs. Engine terminals and yards have been reconstructed to take care of increased business.

TERMINALS, RAILWAY

Snow and Ice Handling. Handling Snow and Ice in Railway Terminals, J. J. Navin Eng & Contracting, vol. 56, no. 20, Nov. 16, 1921, pp. 462 463. (Abstract.) Paper read before Maintenance of Way Club of Chicago.

TEXTILE MACHINERY

Construction. Machining Operations on Textile Machine Parts. Machinery (Lond.), vol. 19, no. 473, Oct. 20, 1921, pp. 57 62, 14 figs. Review of methods employed by British Northrop Loom Co., Ltd., Daisyfield, Blackburn.

TEXTILE MILLS

Hosiery. Durham's New Dyehouse and Steam Plant, Frederick Albert Hayes. Textile World, vol. 60, no. 20, Nov. 12, 1921, pp. 57 63, 9 figs. Describes equipment of Durham Hosiery Mills, Durham, N. C., and gives details of mercerizing buildings in course of construction.

Ventilation. Ventilation and Humidification of Textile Factories, H N. Leask. Domestic Eng. (Lond.), vol. 41, no. 34, Oct. 1921, pp. 155–159, 1 fig. Describes an apparatus designed by A. B. Cleworth meeting all the requirements of humidity and ventilation, etc. Extract from paper read before Rochdale Cotton Spinners' Mutual Improvement Soc.

THERMODYNAMICS

Pressure-Volume Chart. Application of the Logarithmic Pressure-Volume Diagram to Heat Phenomena (Anwendung des logarithmischen Druck-Volumen-Bildes für Wärmevorgänge), K. Körner. Zeit. fur angewandte Mathematik u. Mechanik, vol. 1, no. 3, June 1921, pp. 189–194, 5 figs. Describes how diagram can be developed, giving theoretical and actual logarithmic pressure-volume diagram of a Diesel engine, from which temperature and entropy for every point can also be directly read.

TIDAL POWER

Proposed System. Using the Power of the Tides (L'Utilisation de l'energie des marées). L'Industrie Electrique, vol. 30, no. 702, Sept. 25, 1921, pp. 345–352, 11 figs. Discusses the various systems proposed, classed as, using the water level, velocity of water, or weight of water.

Severn Project. Long Distance Transmission and Tidal Power, T. F. Wall. Electrician, vol. 87, no. 2263, Sept. 30, 1921, pp. 408–410, 3 figs. Discusses the Severn scheme of the Ministry of Transport for an average generation of 500,000 hp. over a 10-hr. day. Scheme involves d.c. generators driven by water turbines; transmission of power to London at 120,000 V. pressure. Electrical difficulties involved. (Abstract.) Paper read before British Assn.

System for Utilizing. Long Distance Transmission of Electrical Energy with Special Reference to Tidal Power, T. F. Wall. Engineering, vol. 112, no. 2912, Oct. 21, 1921, pp. 587–588, 3 figs. Preliminary outline of system obviating difficulty of varying speeds of turbines, permitting use of a.c. generators driven directly from turbines, and offering other advantages. Paper read before British Assn.

TIME STUDY

Stop-Watch. Stop Watch Time Study. Does It Promote Industrial Efficiency? Eng. & Indus. Management, vol. 6, nos. 16 and 17, Oct. 20 and 27, 1921, pp 437–440 and 463–465. Oct. 20: An indictment of the Stop Watch, by Frank B. and L. M. Gilbreth. Defense of stop watch by Carl G. Barth and Dwight V. Merrick in discussion held under auspices of Taylor Society.

U

UNEMPLOYMENT

Factors Affecting. What Construction Can Do for the Unemployed, R. C. Marshall. Eng. & Contracting, vol. 56, no. 16, Oct. 19, 1921, pp. 378–379. Outlines factors vitally affecting unemployment emergency, and discusses steps for reviving construction. Memorandum submitted to President's Unemployment Conference.

URANIUM STEEL

Microstructure. Uranium Steels, Hugh S. Foote. Chem. & Met. Eng., vol. 25, no. 17, Oct. 26, 1921, pp. 789-792, 13 figs. Discussion of microstructure of steels containing a similar percentage of carbon and increasing percentages of uranium. Brief description of influence of uranium as an alloy in structural and high-speed steels.

W

WAGES

Limitation of Output. Limitation of Output, H. M. Vernon. Eng. & Indus Management, vol. 6, no 16, Oct. 20, 1921, pp 428 432, 3 figs. Based on chapter in writer's recently published book on Industrial Fatigue and Efficiency. Includes statistical information obtained during war and now published for first time Discussion as to what is best form of wage and piece-rate payment.

Problems. Wages Problems. Iron & Coal Trades Rev., vol 103, no 2791, Sept 16, 1921, pp. 395-397. Paper by W. L. Hichens on "The Principles by which Wages are Determined" and paper by Prof. Kirkaldy on "The Wages System and Possible Developments." See also Colliery Guardian, vol. 122, no. 3168, Sept. 16, 1921, pp. 797-798 and p. 805.

Z

ZINC ALLOYS

Copper-Aluminum-Zinc. Tenax Metal (Tenax-Metall), Willy Schulte. Giesserei-Zeitung, vol. 18, nos. 18, 19 and 20, Aug. 9, 16 and 23, 1921, pp. 258 260, 268 270 and 278 280. Zinc alloy containing 2.88 per cent copper and 4 44 per cent aluminum, developed during war, practicability of which was confirmed by official investigations and private experiences. Results of tests to determine its value for construction of rods, as a substitute for brass.

MECHANICAL ENGINEERING

Volume 44 February, 1922 Number 2

A Review of Industrial Education and Training

Symposium at Annual Convention of A.S.M.E. Develops Many Principles of Value in Formulating Standard Code of Procedure in Industrial Education

FOR several years The American Society of Mechanical Engineers has maintained a relationship with the universities and colleges of this country, and it was but natural that in time the interest of this organization should be extended toward the technical and trade schools which play such an important part in our system of industrial education.

Two years ago the scope of the Committee on Relations with Colleges was extended to include Education and Training for the Industries, and the name of the committee changed to the more comprehensive one of Education and Training.[1] The symposium on this subject at the recent Annual Meeting of The American Society of Mechanical Engineers was the second public meeting held under the auspices of the enlarged committee. While conforming with the central idea of the convention, by showing how "technical education for industrial employees is for the purpose of *preventing waste* of money, materials, mechanical power, and human energy," the papers and discussions brought out many principles which will be utilized by the committee in formulating a standard code of procedure in industrial education. This can be adopted by the Society and recommended to the industries and the educational authorities.

Two papers were presented and discussed at the session held on the evening of Monday, December 5, in the auditorium of the Engineering Societies Building, New York. Dean R. L. Sackett, State College, Pa., presented the first paper, on Education and Training in the Industries, and D. C. Buell, Director of The Railway Educational Bureau, Omaha, Neb., presented the second, on Education and Training on Railroads. President E. S. Carman presided over the session and Chairman W. W. Nichols of the Committee presented the speakers. An abstract of the papers and discussions follows.

Education and Training in the Industries

By R. L. SACKETT,[2] STATE COLLEGE, PA.

THE education of the worker in the United States has been neglected, while in Europe special types of instruction have been in use for some time. The continued growth of apprentice and continuation schools there indicates that they perform a valuable service. However different the conditions abroad and here may be, the fact remains that more systematic methods must be employed to improve skill, to prepare men for promotion, and to inform our wage earners concerning American industrial methods and ideals.

The early apprentice and his master constituted the first industrial school. The apprentice system failed to meet the need of changing industry and became relatively unimportant, when the age of power and labor-saving machinery arrived about 1876.

CONTINUATION SCHOOLS

Probably the earliest continuation school was that organized in Munich, Germany, where daytime attendance at commercial and industrial schools was made compulsory for all under eighteen years of age engaged in commerce or industry. Besides the continuation of their general education in history, German, mathematics and citizenship, separate classes are arranged for the youths of each trade and in these classes both practical and theoretical instruction are given in the trade by skilled workmen and special instructors. It is to be noted that Germany, in the beginning, brought the public schools and industries into close coöperation in the conduct of the continuation school.

In Great Britain the Fisher Bill for compulsory continued education was passed in the Education Act of 1918. This bill provides for a national system of public education for those 14 to 18 years of age. The system is being applied gradually and the number of students will increase from 600,000 to about 1,200,000 in 1925. Attendance of two half-days per week is required and the subjects are divided into—

a Study of English, Geography, History, Mathematics, etc.

b Instruction in Handicraft, Practical Science, Vocational Instruction.

c Physical Training, including drill, swimming, gymnastics, organized games.

The possibilities of the continuation school were first recognized in the United States about eight years ago, since which time twenty states have established such schools. The need for them as a part of our state system was emphasized by Charles W. Eliot, President Emeritus of Harvard College, who said in 1916:

> A survey of the programs of existing American secondary schools—public, private and endowed—would show that as a rule they pay little attention to the training of the senses and provide small opportunities for acquiring any skill of eye, ear, or hand, or any acquaintance with the accurate recording and cautious reasoning which modern science prescribes.

In support of the continuation school and of industrial instruction in general, the National Association of Manufacturers in convention May, 1913, declared:

> First, It is the purpose of vocational education to save, educationally, that 50 per cent of the children of the land who now leave school at the end of the sixth grade, undirected, unskilled, uninformed, and to train them and others of all ages in the essentials of successful and happy workers in their chosen occupations, in commerce, in manufacturing, in agriculture, and in home making.[1]
>
> Second, It is essential that the teachers in vocational schools shall have had extended experience in actual employment in the occupations taught, to the end that the instruction be practical and meet actual conditions.
>
> Third, Failure has marked every attempt at vocational education not directed principally by employees and employers from the vocations, thereby assuring that the instruction given shall justify the confidence and hope of students, parents and the vocational interests whose coöperation is essential.

In 1913 the state of Wisconsin began a continuation-school program requiring one half-day per week attendance by those between 14 and 16 years of age. Following this example nearly half the states have since enacted laws of a similar character, but most of them require attendance two half-days per week.

In general, the program of the continuation schools in this country has included instruction in English, mathematics, history and then vocational instruction along the trade which the employee is pursuing. Classes in any community are therefore divided according to the principal occupations in the local industries. Attendance is required during two half-days per week and this time

Abstracts of papers presented at the Annual Meeting, New York, Dec. 5 to 9, 1921, of THE AMERICAN SOCIETY OF MECHANICAL ENGINEERS. All papers are subject to revision.

[1] *American Industries*, vol. 13, no. 11, pp. 27–38.

is deducted from the maximum number of hours of employment permitted per week. The employer is required to make provision for the absence of those who are required to attend the continuation school.

Pennsylvania was the second state to provide continuation schools, and in 1915 when the act was passed there were probably "at least 50,000 children between the ages of 14 and 16 who had left school to go to work." Why do they leave the common schools? A very recent report of the Pennsylvania Department of Public Instruction says, "Many children when asked why they leave school to go to work give economic necessity as the reason." Careful and conclusive investigation shows that very few children leave school to go to work because of financial necessity. Thirty-five per cent of the children when first asked give economic necessity as a reason, but the invariable result of investigation is to reduce this number to between 10 and 15 per cent. In the majority of cases further questioning brings out the statement that the desire to leave school is the result of "lack of interest, the failure to make the next grade, dislike of a teacher, distaste for one or another of the prescribed studies, the desire for clothes, spending money, or a craving to try something different." Whatever the reason may be, the fact remains that the secondary- and high-school systems which have been built up in the United States, valuable as they are, do not serve all the needs of all the people and the continuation school is an attempt to appeal to and to serve the objective type of mind, the restless, those who are not adapted to our public schools, or are led to think they do not meet the workers' needs.

The instruction given in the typical continuation school requiring attendance eight hours per week is about as follows:

	Hours
I General Classes:	
English, Vocational Guidance and Occupational Analysis	2
Industrial Geography, Citizenship, Hygiene, Music, Recreation, Arithmetic, Drawing	2
Industrial Arts and Home Projects	1½
Reading for Appreciation	½
II Prevocational Classes for "Self-Discovery:"	
English, Vocational Guidance and Occupational Analysis	2
Industrial Geography, etc.	2
Related Arithmetic and Drawing	2
Commercial Household Arts or Industrial Prevocational Work	2
III Vocational Classes:	
English, Social Science, Industrial Geography	2
Related Arithmetic, Drawing and Hygiene	2
Commercial Home Making or Industrial Vocational Work. (In school, shop or in place of employment under special instructor)	4

Students are assigned to one or the other, according to their preparation and their needs.

What are the purposes of the continuation schools? I quote from the Pennsylvania Bulletin showing a realization of a supreme need and of an immense service which these schools may perform if rightly directed.

> These children must learn how to adjust themselves to the task of earning a living, realize that for practically all of them promotion will be slow and must be earned, that shifting from job to job is a wasteful practice, that they must learn to be responsible punctual, industrious, willing to render cheerful service, if they are to succeed.
>
> Industry grants them little opportunity for instruction on the present job, the line of promotion, or the next job. Especially does industry fail to give them outlook and opportunity toward the permanent job which in a few years will replace the present and temporary job.
>
> Therefore, the continuation school must provide opportunity in fundamental subjects for review and drill on what is already known, for advanced work on what is yet unknown; and for applying what is studied in school to the experiences of every day. The school must help the child to analyze the present job and the job to come, give vocational counsel and vocational guidance, provide opportunity for prevocational shop experience which eventually will become vocational experience. While making the child more efficient on the present temporary job the school must prepare the child for the probable permanent life job.
>
> Because many of these pupils are irresponsible at fifteen years of age and may be more so at nineteen years, there must be training in the things that make for decent, restrained, respectable citizenship and community relations. And because all, both boys and girls, will soon be voters, there must be training in civics, in knowledge of the structure and functions of democratic government.
>
> Lest the pupils become careless in personal habits and in regard to the safety of themselves and others, there must be training in personal hygiene, community hygiene, and safety-first principles.
>
> Because the gang spirit is strong and is the inevitable characteristic of adolescent youth, it must be made a force for right doing through the influence of assembly gatherings and the development of school spirit. Because normal youth must have recreation and leisure, the school must train and guide in the profitable use of recreation and leisure.

The Need for Coöperation. A school system which can perform all these functions or one-half of them is such a valuable asset to industry and hence to society that its aid should be invoked. As the English Labor Party pointed out, these aims cannot be reached without the closer coöperation of the industries with this type of school. None of the legislation so far passed provides for the active advice of industrial leaders in the community. This is important if the continuation school is to fulfill all its functions as above set forth. On the other hand, it would be a serious error to make this type of school merely a manual-training vestibule to factory employment. It is a social institution as well as an industrial one. It is even more important to industry just now that half the effort of our schools be applied to fundamental training in habit and character formation, to right thinking and right acting about work and citizenship.

Apprentice Schools

The Union Pacific, the New York Central System, the Santa Fe, and the Pennsylvania Railroad organized schools for apprentices of one kind or another beginning in 1874 when the Lake Shore & Michigan Southern Railroad began a school for apprentices at its Elkhart, Indiana, shops, but attendance was not compulsory until 1901. In 1886 evening classes for apprentices were organized at the Jackson, Michigan, shops of the Michigan Central Railroad. Later the class hour was shifted to the close of the work but was not on company time. Still later the instruction was shifted to the morning hours and on company time, which is now the general rule. The Pennsylvania Railroad began its apprentice school in 1911 and has gradually extended the plan until there are now eleven schools east of Pittsburgh. At first the position of labor unions toward industrial education was one of hostility, but this has changed in the main and now the International Typographical Union has its own extensive schools, the first of which was established in 1908.

To the foresight and frugality of Germany is due the completeness of her educational program, which for a half-century has excelled in the applications of chemical and electrochemical research to the promotion of her industries. The beet-sugar industry, the production of synthetic dyes, the by-product coke oven, reforestation, the improvement of river navigation, have been the product of scientific education directed toward the development of new resources and the reduction of costs. More recently she has anticipated the solution of the human problem in industry by a plan of intensive practical education for every youth who leaves school to earn a living. Furthermore, her industries have been copartners with the state in the conduct of the program—an important factor in which she still leads the United States.

The experience and present developments in European industrial education are of interest because they exhibit the trend of educational affairs and the effects of the war. Germany now probably possesses the most complete educational system of any country in Europe. Boys are required to attend the usual courses in elementary school instruction up to the age of 14, but during the last year they are allowed in some cases to work in the trade-school shops during their Saturday half-holiday, provided that their health is good.

The trade apprenticeship course is from three to four years in length, which is somewhat shorter than is usual in Great Britain. The distinctive thing about German trade training is that it is given in company shops rather than in public trade schools. For instance, the Siemens & Halske Company have special school shops where apprentices attend for one year and also return for the last three months of their apprenticeship to make a "test piece." The latter is used as a part of the examination for licensing as a journeyman. At the end of the course the apprentice goes before an examining committee of experts who test his knowledge of the trade and to whom he submits his "test piece." Successful ones secure a journeyman's certificate. The apprentice then goes on and obtains a master's certificate. The apprentice training in the industry must be supervised by one having a

master's certificate. Special short courses of about eight weeks' length are given for those who desire a master's certificate. Those who attend the apprentice school in a recognized plant are exempt from attendance at the government continuation schools.

In France there is no national scheme for training artisans. In Paris and other industrial centers, however, evening and Sunday morning classes afford opportunity for trade instruction and there are certain day schools for the combined practical and trade instruction of young men who intend to become expert workmen or foremen.

In Switzerland there is no national system of apprentice training, but a plan of continuation education embodying trade instruction somewhat similar to that of Germany, is carried on.

In Great Britain apprentice training has probably been a more important factor in supplying skilled mechanics than in the United States. One of the most notable schools for the training of employees who enter as apprentices is that conducted by the British Admiralty for more than 75 years, with marked success. The object is to train men for positions as draftmen and subordinate dockyard officers, to select the most capable for advanced training as designers, and to give an employee the largest opportunity.

In the *Journal* of the Institution of Electrical Engineers of Great Britain, vol. 53, p. 571, there is a discussion of the various types of industrial education in operation in Great Britain. The principal ones are as follows:

- *a* A trade apprenticeship combined with evening or part-time study
- *b* A short period of, say, a year in works, then a college course followed by works apprenticeship for college graduates
- *c* Taking a complete college course and then a works course
- *d* Sandwiching college and works training as in the coöperative plan frequently used in the United States
- *e* Taking a complete works course and then a college course.

Mr. Fleming of the British Westinghouse company, describes their course for ordinary apprentices and says that:

> . . . they are first carefully selected on their educational qualifications and character. After a short probational period to test their practical aptitude they are admitted to the apprentice school.
>
> Instruction is given about five hours per week to all apprentices on company time and the firm also supplies books and stationery.
>
> The apprentice is paid the regular rate during his school hours.
>
> The instruction is of two kinds: general and trade. The first is a continuation of the apprentice's regular education and is important as the standard of education is low for this class of people in England.
>
> The trade instruction is given by members of the engineering staff, including leading foremen and shop engineers. Drawings, lantern slides, and shop demonstrations are used to teach processes.
>
> An interesting feature is an elective committee of apprentices representing the different trades, which coöperates with the school staff.
>
> The most promising apprentices are selected as a result of their school work and are sent for one day per week to the Manchester Municipal School of Technology on company time and expense.

Another works school which has caused considerable comment is at Manchester, England. It is devoted to general education and to trade education. I quote a significant paragraph from the description:

> Before a trade training in England can be effectively given it has been found necessary to lay the foundation of a general education of a deeper and more solid character than can at present be obtained in a primary school.

Is this true in the United States? Are we attempting to make skilled workmen, and losing sight of the importance of general education and intelligent citizenship?

In one British plant, which is believed to be the Vickers Company, the apprentice attends school four hours per week for four years. His general education includes 18 months of mathematics with shop applications, elementary science, that is, fundamental physics, principles of heat, electricity and mechanics. He has also freehand drawing to relate the hand and eye. The general subjects include also civics, industrial history, written and spoken English, the laws of health and first aid.

The trade instruction begins after the above period of 18 months of general education. The students are now divided into two classes—those to follow mechanical engineering lines and those to follow electrical engineering lines. The treatment of the two is quite similar and only one will be described.

Six months are devoted to the development of mechanical principles, after which the groups are divided into some 12 trades and are taught the principles of their trade with demonstrations by expert foremen.

> Boys meet their foreman in the school room and there discuss with him in class matters of trade practice. This is of the most healthy character, and is doing much to remove that natural diffidence which boys normally experience in approaching their foreman upon such matters.
>
> The lecturing staff at the works school is composed of half-time lecturers all of whom are works engineers. Mostly university graduates volunteer their services.
>
> This association of future leaders with future workmen and foremen, superintendents, etc., is *valuable*. These advantages belong only to works schools.
>
> During the last two years a unique development has occurred. The main body of apprentices is self-governing. Each class elects one of its number to represent its interests and these come together once a week and form an apprentice council. The Council has a chairman and secretary. Council organizes social functions and acts as an apprentice tribunal.

In the latter capacity it has already done good service. It has settled minor differences, and arbitrated in such cases with more satisfaction to apprentices than could have been given by any other method.

Apprentice Training in the United States

While the number of apprentices in proportion to the number of skilled workmen may be less today than in the past, the training of apprentices is an important factor in some of our industries—in railway motive power, in the metal trades and to a lesser extent in other fields. There are two classes: first, those who have had a grammar-school or a high-school education, and, second, special apprentices who are graduates of technical colleges.

The practice of one of the electrical companies will illustrate a typical plan for the first class. Apprentice trade training is given to prepare draftsmen, patternmakers, foundrymen, machinists, toolmakers, electricians and junior engineers.

Applicants are first accepted on probation for a period of three months.

> At the completion of each month of the probation period their names are brought to the attention of the Trades Apprentice Committee, at which time their record is reviewed for the purpose of determining their aptitudes and characteristics. At the completion of the third month a definite decision is made by the committee as to whether the young man shall be placed on the course, recommended for a regular position in the organization where they can be under further observation, or released from the company as unsuited for the work.
>
> When the probation period is completed an agreement is entered into between the company and the apprentice and his parents, and outlining what the company expects of the apprentice during his course and what the apprentice may expect from the company. The apprentice is then placed in a special training department in the factory where he receives preliminary instruction in the operation of various machine tools under the direction of especially qualified instructors.
>
> The training department turns out a product the same as other departments in the factory, but it is particularly equipped to take care of young men who have had no previous experience on machine-tool operation. Supplementing the shopwork each apprentice reports to the trades apprentice school four hours per week. Two hours of instruction are given up to blueprint reading, sketching and mechanical drawing, including tool design. The other two hours per week are devoted to economics, science and a study of shop problems, including the application of mathematics to manufacturing operations.
>
> After several months' experience in the apprentice training the young men are placed in the different manufacturing divisions on various kinds of work to thoroughly acquaint them with our products, organization, personnel and policies. As they progress through the course more difficult assignments are given them, both in the shop and in the trade apprentice school.

Students are "upgraded" and promoted and wage scales determined by careful supervision and records of performance, character and habits. The drafting course and junior engineering course are open only to high-school graduates. Advanced technical training is available for all trade apprentices in an evening school supported by the industry and in evening classes at technical institutions in the city.

Special Apprentice Courses

Special apprentice or graduate-student courses for college technical graduates are given by an increasing number of corporations. These courses are designed for the dual purpose of acquainting the student with the processes and product of the company and of finding the line to which each student is best adapted. The method frequently employed is to devote one year to practical experience in design, assembly, and testing with weekly conferences with and

instruction by the engineers and executive staff. After the particular line of work for each to pursue is decided the subsequent training is more intensive in that particular line and leads to design, research, testing, and sales or executive positions.

The motive-power departments of the Pennsylvania and New York Central systems have had courses for college graduates which have led students in the past to enter a few of our technical schools that provided special training preliminary to service in the motive-power departments. This plan was successful until the railway shop unions were able to obtain an agreement with the director of the railroads under government control that college graduates should not be so employed. This was not only short-sighted but unfair to college-trained men and to the railroads.

The general apprentice courses are effective where they are employed in training skilled mechanics and in preparing men of ability to become foremen and minor executives. The special apprentice courses serve as vocational guides and acquaint the student with the product, methods of manufacture and business ideals and practices of the company. There is no doubt of the value of such courses. The objection is raised that they are too long and that college students avoid apprentice courses, some of which are four years in length. This objection could be partly met by a coöperative plan in which the industries accepted undergraduates as apprentices, employing them before graduation for one or two summer periods of three months.

General Instruction for Skilled and Semi-Skilled Employees

This country has developed types of instruction unknown abroad, adapted to the needs of mechanics, electrical workers and a wide variety of other trades unknown in other countries.

Correspondence Courses. The English type of extension lecture course was first introduced here about 1891 and it soon replaced the old lyceum. This variety of extension instruction was not adapted to the needs of the average industrial employee. It was soon supplemented by correspondence courses, and private correspondence schools for instruction in a wide variety of subjects sprang up and flourished. A number of them are still active—one claiming to have a million students enrolled. The public and private correspondence schools have done a great service for those who had the ambition and ability to pursue the work.

The Pennsylvania Plan. Classes are organized in the shops, power plants, and wherever a group of men or women desire to study industrial or engineering subjects. A teacher is selected from the executives, who knows by experience the problems of the machine shop, boiler room or other parts of the industry in which the group is employed. The subject which they desire is prepared in special form adapted to the type of instruction.

The class meets with a teacher once or twice a week in a room equipped and provided by the plant or in the city schools or in the Y. M. C. A. The time is usually at the close of work hours and before the workers go home. An increasing number of companies allow a part or the whole instruction to be given on company time. Some pay the cost of lessons, drawing materials and instruction as a bonus to those completing the course satisfactorily.

Supervised Home Study. A plan devised where the group desiring a subject is too small to warrant the expense of an instructor or where an isolated employee desires an advanced subject, is to provide correspondence lessons as is usual but have an instructor or supervisor in reach of such student, who may be consulted at a stated place and time to answer questions and explain difficulties. The answers are sent to the college teachers for grading.

The Engineering Extension Division of the Pennsylvania State College organizes the three types of instruction, viz., correspondence and extension classes and supervised home study, for over 7000 men and women employed in the industries of Pennsylvania. The subjects cover a wide field which is constantly being extended. Special lesson material has been and is being prepared; or the texts produced by the University of Wisconsin Extension School are used. Courses for college credit in engineering are given by both institutions mentioned under proper restrictions.

Coöperative Courses for Technical Students. It is not the purpose of this outline of the various types of industrial education to discuss college curricula for technical students who expect to enter industrial or engineering occupations. A word concerning the various forms of coöperation between the schools of technology and the industries, however, seems appropriate.

For years the industries have employed college men during the summer vacation, or for a half-year or more before graduation. The coöperation was at first more or less loose and informal, with a growing tendency to require reports from the industries and from the students on the quality of work done, its character, and the comments of the "boss" on the human qualities of each student.

The first systematic attempt was that made by the University of Cincinnati, under Dean Herman Schneider, in 1906. The plan is for the student to spend two weeks in pursuing his studies in course and the following two weeks in a shop somewhat as an apprentice learning a trade. Thus alternate periods are devoted to class and to practical work. Groups alternate so that the same subject is repeated in class and in the industry. The student is paid a wage increasing with his practical experience.

The plan was first applied to students in mechanical engineering and later to civil engineering students and those following business pursuits. It took about five years of eleven months each to complete the course, and it was stated that "present coöperative students who have been at the University of Cincinnati four years are of more value to the industries than the ordinary college graduate who has had a four-year course and two or three years as a special apprentice.

A number of other institutions have adopted a coöperative plan differing only in the length of the period spent in the class room between periods in the shop or in other details. The plan has certain merits now well recognized.

The Massachusetts Institute of Technology has established a course in coöperation with the General Electric Company at its Lynn, Mass., works which was described in detail by Prof. D. C. Jackson and M. W. Alexander at the May, 1921, meeting of the A.S.M.E. in Chicago.

Under this plan the student pursues two years of the regular course at the Institute as heretofore. At the close of the sophomore year, the summer period of 13 weeks is spent by all those accepted as coöperative students at the Lynn Works of the General Electric Company. The succeeding terms of 13 weeks each are spent alternately by one-half the class at the works and at the Institute except that the last term is pursued at the Institute by all students. The coöperative course is five years of eleven months each in length, a month of vacation following each eleven months' term.

Foremanship Training. Probably no educational factor in industry has been so emphasized by the war as the need of special training for the foreman. The character of his job has changed and his importance has increased. He determines certain factors which decide whether production is on an economical or a wasteful basis. He also represents the management or may do so in the new relations with employees. He is no longer employed to "hire and fire," but to organize, assist the accounting department in analyzing costs and reducing them, to coördinate more closely with other departments and to maintain good personal relations with his men as the representative of the management.

Numerous plans of instruction have been prepared to be given in short intensive courses of two weeks, or by correspondence, or by weekly works meetings of the foremen in a plant. Quite frequently, however, it is the management that needs to take the course in order that the importance of the foreman's job may be appreciated and in fact officials are taking new and increased interest in education for workingmen, foremen and for minor officials.

Foreman Teacher Training. Congress passed the Smith-Hughes law designed to give each state a specified amount of federal funds if matched by an equal appropriation of state funds for the purpose of training industrial teachers. This has been interpreted as applying to foremen who may be given "foreman teachers' training." The good foreman has always been a teacher, but recent industrial conditions and the numerous coöperative schemes for training secondary-school, high-school and college students in industry have magnified the foreman's importance as a teacher. Many are inclined to smile at the idea of formal training for the foreman teacher, but the fact is that the act offers opportunities for practical training of foremen in the art of teaching that may have an important effect on the loss of material, human effort and wages in poor work or retarded production.

It is a wise industry which utilizes every honest strategy to prepare it for world competition. If the Manufacturers' Association were to confer with the Federal Board for Vocational Training which administers the Smith-Hughes funds and approves courses, a much more valuable training might be devised.

The Young Men's Christian Association has for years conducted courses in mathematics, drawing, auto mechanics and other subjects of service to those employed in the industries and has aided thousands of young men to get a better knowledge of their daily job. Kindred organizations are doing likewise.

Conclusion

There are numerous demonstrated educational aids to the worker, and whatever helps him will improve industry and society at large. Neither our public-school authorities nor the industries have fully realized the stabilizing value of practical education. The reduction of waste and the increase of efficiency in production are matters of education of which both the employer and the employee have need.

Furthermore, our educational work in the industries has been mainly to help the man in his daily job. We need to look farther ahead and use sound pedagogical methods in presenting to the employee the principles of economics, of simple finance, of factory operation and company policies. Some improvement in our industrial relations is possible by the use of the simplest educational principles heretofore largely ignored.

Education and Training on Railroads

By D. C. BUELL,[1] OMAHA, NEB.

THE education and training of railroad men is a subject which has received considerable attention from railroad executives for many years. The history of pioneer railroad-development work in this country forms one of the romances of the new world. Less than 100 years have elapsed since the first American railroad was projected, and the subsequent development carried with it those possibilities that attract men, both young and old.

In the early days the whole railroad was a school. Home boys importuned the agents of the railroad to be allowed to learn telegraphy and station work. It was a privilege to be allowed to ride on an engine or on a train so as to learn to be a fireman or a brakeman, or to help switch cars in the yard or truck freight in the freight house, or even to work in the track gang or around the engines in the roundhouse. There was always a trained man ready to step into almost any minor job on the railroad and handle the work connected with the job successfully.

While the old apprentice systems obtaining in most shops were in effect in the railroad shops of the country at an early date, nevertheless the first educational work of a general nature inaugurated by the railroads was in connection with associations of engineers, executives, and others brought together for the purpose of adopting standards of equipment, engineering, and operation. Much of the educational work on railroads has been done through the medium of such associations, members of which in many cases had the power to pass officially on standard methods and practices presented for their consideration.

These men were confronted with standardization problems because of differences of gage of the railroads, the necessity for transferring freight and passengers from one road to another, etc. Their deliberations and conclusions have made possible our unified transportation methods of the present day.

New Educational Requirements of the Roads

Up to the last twenty years sufficient new railroad mileage was built each year so that enough new positions were created to make promotion rapid. Today things are entirely different. There has been so little new mileage built in the last few years that opportunities for promotion in railroad service have been far below normal. Men ready for promotion have had to wait years before their opportunity came.

During the last fifteen years political interference, both state and government, in railroad operation tended to remove from the railroad executive his power of initiative and his ability to do big things in a big way. Consequently, in a manner almost unnoticed by himself or his community except in its cumulative effect, his prestige was reduced. During this same period the labor unions placed barriers in the way of their members training men to take up railroad work. Rules and restrictions forced upon the railroads and counter rules and restrictions imposed by the railroads made railroading much less attractive to the youth of the country than formerly. There is a reaction at the present time following the experiment of government control of the railroads, that would indicate the possibility of a partial return to the older conditions of management which made railroading more spectacular and consequently more attractive to youth.

Railroad executives have not been insensible to these changing conditions. Most of the railroad companies in the past twenty years have experimented with the training of apprentices in the shops. Some of the companies have very efficient apprentice systems, among which those of the Sante Fe and New York Central stand out preëminently.

Individual executives fired with enthusiasm have made sporadic efforts at educational work of almost every kind in almost every department in individual organizations, but it was not until about 1905 that a comprehensive plan of educational work for a railroad organization was seriously considered.

Basic Efforts in Educational Work

At that time the late E. H. Harriman called on the executives of the various lines under his control to work out some plan of educational work which would provide opportunity for ambitious employees to increase their knowledge and efficiency and fit themselves for promotion.

On the Southern Pacific Railroad, under the leadership of Mr. Kruttschnitt, a plan of training students in railroad operation was evolved which was in effect for a number of years. Young men selected for this training were given a four years' course of directed practical work to give them experience in the various departments of the railroad and to fit them for supervising positions when their period of training was completed. This plan, like any other new plan, had its faults as well as its good features. The fact that it is no longer followed is due to lack of placement opportunities rather than to a failure of the system per se.

Following the lead of the Southern Pacific, the Union Pacific Railroad Company in 1909 organized a Railway Educational Bureau on much broader lines than the Southern Pacific's plan and with an entirely different objective.

The Union Pacific idea was to offer to every ambitious employee in the service an opportunity to increase his knowledge and efficiency and place himself in line for promotion. In order to make the service equally available to all employees instruction was offered by correspondence.

In building up this Union Pacific educational plan it was necessary to prepare practical lesson texts on almost every phase of railroad work. The problem of preparing such texts for all classes of employees involved the expenditure of several years' time and of a considerable number of thousands of dollars. The response of the employees to this educational opportunity was greater by far than had been anticipated. There were as high as thirty to thirty-five per cent of the employees of the Union Pacific enrolled as students under this plan.

Operation of Railway Educational Bureau

As an example of the operation of this plan, track laborers were given opportunity to study those things which they needed to know to become successful section foremen. Not only actual problems of track work but other subjects such as a working knowledge of the time table and the book of rules, a non-technical knowledge

---

[1] Director, Railway Educational Bureau, Omaha, Neb. Mem.Am.Soc.M.E.

concerning the operation of signals, instruction concerning emergency repairs to the telegraph line, instruction concerning the operation of track motor cars, instruction about such uses of concrete as might be a part of a section man's routine of duties, a thorough drill in section foreman's accounting for labor and material, etc., were offered them for study. In other words, the Bureau furnished to employees practical information about their duties and the duties of the positions ahead of them that would assist them to become more efficient and place themselves in line for promotion.

Other railroads interested in this educational work undertook the problem of working out similar service for their employees. A start was made on the Chicago & Great Western and on the Pennsylvania to establish similar educational work, but the time required to prepare the texts and the considerable cost involved in inaugurating the plan seemed to prevent other companies from going very far with the idea.

The Union Pacific educational work was extended to other Harriman lines, including the Illinois Central and the Central of Georgia. Plans were then made for extending this educational service to all of the Harriman lines, but the demand for this kind of work all over the country was such that Harriman line officials in conference decided to turn over the work to the author, who had originated and directed the plan, and thus made this educational service general in its nature and available for any and all railroads interested.

Since 1913, the Railway Educational Bureau with its office at Omaha, Neb., has functioned as a semi-commercial institution coöperating with any railroad management interested in offering educational opportunities to its employees. At the present time this Bureau is coöperating with nearly 100 railroad companies, representing well over one-third of the railroad mileage of the United States. Interested employees pay a nominal fee for the service, the railroad companies making the collections for the Bureau in the same manner they do for insurance companies, watch companies, board, etc.

While this Bureau has provided the railroads with a comprehensive educational plan available for their employees, changing conditions require that much more than this be done.

Even Broader Solution Must be Sought

Old methods of apprenticeship no longer function. There must be new methods inaugurated for training new employees before inducting them into the service, for the training of foreigners and those with educations too limited to allow them to study by correspondence. Then, too, there is needed special training for employees selected for promotion to minor supervising positions before they actually take up their work of supervision.

A number of prominent railroad executives are giving careful thought to methods by which the educational necessities outlined in the preceding paragraph may be accomplished in a practical manner.

There is also needed, some method of keeping railroad employees informed of current problems, changes in standards, new methods and practices.

The Railway Educational Bureau at the present time is coöperating with the Society for Visual Education in Chicago, in the working out of a plan for a library of railway moving-picture films which will be available for all of the railroads in the country on a distribution system similar to that in effect through film exchanges to the motion picture theaters. This plan presupposes the purchase by individual railroads of projection machines which will be located at division points, general offices, etc., so that weekly programs of educational pictures can be furnished for employees and their families.

It is realized by railroad executives that the whole subject of railway educational work ties up with two other very important problems, one the employment of men and the other, directed personnel work following employment.

It is the belief of some of those who have made a study of this subject that the trend of thought in the railroad world will lead to the adoption of a centralized office to which railroad executives can go for aid in educational and personnel problems. One of the functions of this centralized office would be to prepare educational matter suitable to, and available for, the use of the railroads. This centralized office should handle the railway library of moving-picture films, and should also coöperate with individual roads in working out individual educational problems in connection with the training of new employees, apprentice training, intensive training for men selected for minor supervising positions, etc.

DISCUSSION ON EDUCATION AND TRAINING

Dr. Ira N. Hollis,[1] Past-President A.S.M.E., emphasized that the need is to train men not only for high efficiency in the industries, but also for greater satisfaction with their work. The inevitable consequence of the latter would be that their spare hours would be usefully occupied in those things that tend to the greatness of our country. He hoped that the A.S.M.E. as it gains in opportunities and progresses in influence, might have the foresight to take a hand in this most important question before the industrial world today.

Dean A. A. Potter[2] thought that in industrial education, too little attention had been paid to the talents of the learner.

Prof. A. L. Williston[3] while agreeing with the authors of the papers that progress has been made in industrial education, contrasted what has been done with the need that exists in all the different lines of industry today. He criticised the industries themselves for making almost no effort to supply this need.

He hoped that the Society would go into this matter with a considerable degree of seriousness, and that it would have vision enough to see that back of this is a contribution comparably greater than any other it can make to the profession and to the country.

To J. A. Randall[4] it seemed that since industry wants individuals trained more definitely for the job, it is necessary to have more definite conceptions of the duties to be performed in the industries.

In addition, employees should be trained in company policy, in attitude toward the company, the community, and society.

The problem of industrial training is so large that no single industrialist or group can solve it, and he suggested that the Society join with other organizations in improving courses, which so far have given the means of getting a living without conveying the power to live a life.

Edward Robinson[5] gave a few vital statistics showing just what fraction of the population the problem in hand applied to, and he, in turn, considered the committee was on the right track and hoped the Society would support further work.

L. W. Wallace[6] thought that much could be done through the Federal Board of Vocational Training if the engineer-citizens of the country would take a greater interest in its work. He said that an engineer could, with advantage, be appointed on the Board.

C. B. Connelly[7] emphasized Mr. Wallace's statement. This Society stands for education, if it stands for nothing else, and it is the duty of the Society to take up this important work. We have an engineer in the cabinet—the first since the time of George Washington, and the engineering point of view is being incorporated into government matters. Now, therefore, is the greatest opportunity for success.

A. B. Clemens[8] contributed a written discussion of both papers. His discussion of Dean Sackett's paper detailed the work of the correspondence schools under contract or agreement with industrial concerns for the instruction of employees, and his discussion of Mr. Buell's paper supplemented this information with a review of the work of the correspondence schools with the railroads.

Avoidable Waste in Car and Locomotive Operation

By WILLIAM ELMER,[1] ALTOONA, PA.

The average freight locomotive travels less than 60 miles per day. It spends about half of its time either in the hands of the transportation department moving trains or ready to move them, or in the hands of the motive-power department being repaired and prepared. There is naturally avoidable waste in each department, and questions which may accordingly be asked relate to whether the engines are properly loaded and properly used. The present paper outlines the procedure for determining this, and one of its several appendices gives a method of working out the most economical tonnage for loading the freight engines of any division, based on actual practicable performance in everyday operation. The treatment considers the value of the locomotive, taking account of interest, depreciation and taxes; the relationship between straight-time and overtime rates for road crews; the quickening up of the time of the trains by a reduction of tonnage and the increase of the time the crews are on duty by an increase in tonnage. When these matters have been sufficiently studied in the light of the recorded facts, the question relating to proper loading can be intelligently answered.

The author discusses avoidable waste in the operation of cars under three heads: (a) Their utilization in the hands of agents, shippers and consignees; (b) their handling and dispatchment in yards and on the road; and (c) their repair and inspection.

Things contributing most to the reduction of waste in car and locomotive operation are coöperation and teamwork. If a division superintendent can be assured that everything is being done that can be done to have every available engine in service that can be put in service and that every engine dispatched is being loaded to the maximum number of cars it can economically haul, then he is assured of an economical performance and an avoidance of waste in the operation of both locomotives and cars.

LOCOMOTIVES, the first of the two divisions set forth in the title, are classified into major groups as freight, passenger, shifting and work locomotives. There are 65,000 locomotives on the railroads of the United States and half of them are in freight-train service. Thirty-two thousand and eighty locomotives earned a freight revenue of \$4,325,078,866 in 1920, or an average of \$135,000 per locomotive per year. Each engine made an average of 59.3 miles per day or 1800 miles per month. The average freight engine earned for its owners \$370 per day or \$6.25 per mile run. This is at the rate of \$15.40 per hour or about 26 cents per minute. The striking thing in the group of facts above presented is the figure of 59.3 miles per day made by the average freight locomotive. How can we excuse an average mileage for all the freight locomotives in this country of less than 60 miles per day? We can picture the average freight locomotive rolling along the rails at 15 miles per hour and that means less than four hours out of each twenty-four actually moving trains. The locomotive spends its entire time either in the hands of the Transportation Department moving trains or ready to move trains, or in the hands of the Motive Power Department being repaired and prepared. Roughly we may say that the engine is in the hands of each of these departments about half the time. Of course there is avoidable waste in each.

Taking up first the Transportation Department, there are two broad inquiries which may be made: (*a*) Are the engines properly loaded? (*b*) Are they properly used? Assuming that suitable engines have been furnished the Transportation Department, or taking the engines on any division as we find them, how are we to know when they are properly loaded? If a dynamometer car is available, road tests may be run to determine the drawbar pull of the engines and to measure the resistance of trains of various make-ups on the ruling grades at the desired speeds. In the absence of this facility it may be desirable to outline the procedure.

A—Are the Engines Properly Loaded?

A track chart of the road is necessary, giving the distances from the starting point to the beginning and ending of each curve and tangent, with the degree of curve, and elevations of points where the grade changes. With these data a true profile may be plotted, showing the elevations above sea level and the actual grades; but this profile will not be fully representative of the resistances encountered by moving trains until it has been transformed into an equivalent compensated profile by superimposing the curve resistances on top of the grade resistances for each direction of traffic. We can imagine a level railroad so full of sharp curves that a very considerable resistance would be experienced by a moving train. Many experiments have been tried in an effort to find how much resistance various curves offer to a moving car, and we will take 1 lb. per ton of 2000 lb. per degree of curve. The resistance due to grade is fortunately an exact mathematical quantity—20 lb. per ton for each 1 per cent of grade. Therefore each degree of curve offers the same resistance as a 0.05 per cent grade. A 6-deg. curve had the same resistance as a 0.3 per cent ascending grade. A grade which is climbing upward at the rate of 26.4 ft. per mile or 0.5 per cent and has in it a 6-deg. curve, or 955-ft. radius, will therefore have superimposed on the true grade of 0.5 per cent the equivalent resistance of a 0.3 per cent grade due to the 6-deg. curve, or a total equivalent grade of 0.8 per cent. Of course, to a train coming down this hill the equivalent grade would be the difference between these values, or 0.2 per cent.

Having determined the equivalent grade, it will be necessary to decide whether it can be operated as a momentum grade or not. If the length of the grade or other physical conditions on the approach prevent attaining any considerable speed, the dead pull of the locomotive will have to be depended on to get the train over. The tractive power of a locomotive is readily calculated from a very simple formula where p is the boiler pressure in pounds per square inch by gage, d the diameter of cylinders, l the length of stroke and D the diameter of the driving wheels, all in inches. For a simple two-cylinder engine, tractive power = $0.85pd^2l/D$. When a locomotive is moving, some of its tractive-power effort is used to overcome friction of the engine and tender, and on a grade some more is needed to lift its weight against gravity, and at speeds of more than six or eight miles per hour the boiler becomes a factor in its inability to furnish enough steam to follow the pistons with full pressure under long cut-off conditions, so that some more complicated formula becomes necessary in the calculation of the tractive power required for moving trains. Besides the resistances due to curves and grades, trains are affected by journal and flange friction, wind, rolling resistance, temperature, etc.

It is a well-known fact that trains cannot be loaded on tonnage alone. One hundred empty cars weighing 20 tons each would be a 2000-ton train, and might overload an engine to the stalling point, whereas the same engine on the same grade would handle twenty-five 80-ton cars with no trouble. The number of axles is the important factor, and in order that a long empty train may have the same resistance as a short loaded train, it is necessary to use a factor for each car known as the adjustment factor, and this factor will vary with the different physical conditions met with on different divisions.

Having discovered the adjustment factor for any given division, and knowing the principal types of freight engines in use on that division, it is well to construct tractive power-speed curves for the various engines, and plot on the same sheet adjusted-tonnage train-resistance curves on various level and compensated-grade tracks, so that the intersection of the tractive power curve with any given grade will show the speed that could be maintained with a full-tonnage train on that grade.

After having completed the above described investigations and having before us the equivalent profiles and the speed curves on various grades, we can lay out a schedule of the running time between the various towers, adding the necessary time to cover the initial and final terminal delay, water stops, coal and fire-cleaning stations, interference from passenger trains, etc., and bearing in mind the overtime limit based on a speed of $12^1/_2$ miles per hour for the distance between terminals and the time the crew is on duty.

---

[1] Superintendent, Middle Division, Pennsylvania Lines, Altoona, Pa. Mem.Am.Soc.M.E.

Presented at the Annual Meeting, New York, December 5 to 9, 1921, of The American Society of Mechanical Engineers, 29 West 39th Street, New York. Abridged. All papers are subject to revision.

Now comes the crux of the whole matter. After the tonnage has been established, what are the results on the road? Do the trains lose so much time sponging or setting off cars with hot boxes, or draw heads out or brake rigging down, or due to interference from other trains that they cannot get over the road without excessive overtime? If the dispatching and terminal and road supervision are all that they should be and a record has been made for a sufficient period from which may be drawn reliable conclusions, we can determine whether the overtime is excessive—in which event the tonnage should be decreased—or if the majority of the trains get over the road within the overtime limit, then the tonnage should be increased. Appendix No. 1 contains the description of a graphical report showing each morning the performance of each of the previous day's trains, both slow and fast freight, plotting the time on duty from called to relieved against the percentage of the full tonnage loading of the engine utilized. This gives the train master, road foreman of engines and superintendent a review of the preceding day's operations, and any falling away from the standards set up on the part of the subordinate officials whose duty it is properly to load the trains is quickly brought to light. In Appendix No. 2 is given the method of working out the most economical tonnage for loading the freight engines of any division, based on actual practicable performance in everyday operation. The treatment considers the value of the locomotive, taking account of interest, depreciation and taxes; the relationship between straight time and overtime rates for road crews; the quickening up of the time of the trains by a reduction of tonnage and the increase of the time the crews are on duty by an increase in tonnage. When these matters have been sufficiently studied in the light of the recorded facts, we are in a position to answer the question, Are the engines properly loaded?

B—Are the Engines Properly Used?

So far as the Motive Power Department is concerned, it is important to have reliable reports which present promptly to the responsible operating officers, on the succeeding day if possible, all the pertinent facts concerning the performance of the locomotives available. These reports should cover not only the utilization made of the serviceable locomotives but also of all those laid off for repairs, both in the roundhouses and the back shops. The more promptly the work is done the more engines will be available for service and the smaller will be the number required to be purchased and to bear interest and depreciation charges. To this end the facilities at the engine terminals should be ample to inspect promptly the incoming locomotives and send the reports to the dispatcher, who can at once call a crew in case the engine has only light work which can be completed by the time the crew reports. The fire-cleaning pits and facilities for handling ashes, coal, sand and water should be in duplicate at important points, and at one well-known freight-engine terminal it is possible to clean the fires and prepare for service 400 locomotives per day. Hot-water systems for washing and filling boilers save time, and drop tables or unwheeling hoists should be provided for handling driving wheels, spring rigging and driving-box repairs. Ample jib or overhead cranes should be installed in all important enginehouses, as the rods, pumps, pistons, smokebox fronts, etc., of modern locomotives are now so heavy that mechanical appliances must be used to reduce the cost of handling and save time in running repairs. The enginehouse referred to above at times furnishes the power for ten eastbound trains in two hours and at the same time ten to fifteen engines an hour for westbound trains. An operation of this magnitude requires close supervision in order that waste of power and loss in efficiency may be avoided.

CARS

The avoidable waste in the operation of cars may be considered under three heads:

a The utilization of cars in the hands of agents, shippers and consignees

b The handling and dispatchment of cars in yards and on the road

c The inspection and repair of cars by the maintenance of equipment department.

A—The Utilization of Cars in the Hands of Agents, Shippers and Consignees

The committee of engineers appointed by Secretary Hoover some months ago to investigate waste in industry made a most amazings report. They undoubtedly gave this question careful study and the report that they made brought out the fact that the production of this country could be immediately increased about 50 per cent by the full utilization of existing facilities. The managements of the industries of this country are acknowledged to be the most efficient known and the railroad managements are no exception, therefore it is the more surprising to find such disparity between the present efficiency and the attainable.

So far as the railroads are concerned, one great means that suggests itself is the increased use of cars in the hands of agents and shippers, which necessarily involves the promptness with which they are loaded and unloaded and the extent to which they are loaded, i.e., that the maximum loading be secured for the car in the minimum time, etc.

Maximum car loading is a matter of dire necessity during periods of car shortage. If is also very essential to the economic conduct of transportation. During recent months the necessity for conserving cars has been decreased by the small volume of tonnage handled by the railroads; the requirement of economy is more urgent than at any time within the past eighteen months. This is all a matter of education and a spirit of coöperation on the part of the public. When the railroads had more business than they could handle the local officers were being urged to get out and interview the shippers, the underlying idea being to secure their coöperation, especially in the matter of better and heavier carloads. Distinct improvements were noticeable and the effort proved its worth. With the slump in traffic the "drive" lost its punch and there is a tendency on the part of the shippers and railroad men alike to let down in their efforts to secure maximum loading. This "line of least resistance" method is resulting in considerable less-than-capacity loading.

It is a fact, not generally recognized, that car loading affects the cost of railroad operation very seriously, not only because the paying load may be a small percentage of the gross train load, but also because lightly loaded cars require more tractive effort per ton than heavily loaded cars; e.g., the average weight of a car is from 15 to 20 tons while the average weight of all commodities is averaging approximately 27 tons. The load of the car itself must be hauled with every movement of the contents and requires as much tractive effort on the part of the locomotive per ton to move this weight as it does for the contents, therefore the importance of keeping the percentage of lading to total weight as high as possible is self-evident. This question has assumed a very different aspect to the shipper since the passage of the Transportation Act, which stipulates that the rates must be sufficient to earn a fixed return on the value of the properties. Any waste due to the light loading of cars adds to the operating cost and thereby to the rates necessary to earn the specified return. The shipper therefore has a new interest in effecting economies of transportation and can contribute to that end most effectively by coöperating in the heavier loading of cars.

During the period February to August, 1920, the average loading of cars in the United States increased from 28.3 tons to 29.8 tons per car. As a result of this coöperation on the part of shippers there was a gain of carrying capacity equal to approximately 112,500 cars. From time to time we have noticed by the public press that there is a shortage of 100,000 cars in the United States, and as such is considered a serious matter to the trade of the entire country, it is very apparent that the simple feature of increasing the load in each car 1.5 tons more than liquidated the alleged shortage.

General practice permits the loading of cars 10 per cent in excess of the marked capacity. There are great possibilities in the utilization of this margin, for with many classes of loading great advantage may be taken of it to gain one car in every ten and to increase the average carload correspondingly.

There are many commodities moving which will permit of the making of trade units to correspond to the capacity of the car; this has been done with cement and other like commodities. The trade unit for cement shipments was set at 144 bbl. for a 50,000-lb.

capacity car; 173 bbl. for a 60,000-lb. capacity car; 231 bbl. for an 80,000-lb. capacity car and 289 bbl. for a 100,000-lb. capacity car. The establishment of this standard encourages the loading of cars to capacity. If this were done with flour and all similar commodities great assistance might thus be rendered to the railroads.

The agent through close association with shippers is in the best position to encourage maximum loading. It is often decidedly hard to convince shippers that they are not loading their cars to cubical capacity. This is particularly true of the coal operators. The best means of producing convincing evidence of the empty space in a car is to show the shipper a photograph of the car which will speak for itself, and we have found a kodak to be a most helpful instrument in increasing the tons per car. The cars may easily be intercepted and photographed at scales or in classification yards.

The prompt release of cars under load is a large factor in the efficiency of the car. Most shippers and consignees are reasonable in this respect and will give us their best efforts if the matter is handled with them in a diplomatic way. After urging the shippers and consignees, the railroad then has a very important part to play by the prompt movement of cars, whether loaded or empty; it being purely psychological that after urging the shipper or consignee and then failing on our own part would necessarily breed antagonism.

B—The Handling and Dispatchment of Cars in Yards and on the Road

After cars have been loaded and waybills furnished by the agent to transport freight from point of origin to destination, it becomes the duty of the train master to arrange for movement and delivery with the least possible delay consistent with economical operation. This necessarily involves good organization and effective supervision to accomplish proper movement through yards and over the road. Normally cars are weighed at the first track scale encountered after departure from shipping point, for the purpose of ascertaining proper charges for transporting freight which involves the agent at the scales, who is responsible for securing accurate weights as a basis for applying the freight charges. As a rule, the weighing is performed in a yard consisting of receiving and classification tracks. Trains arriving in the receiving yard are subjected to inspection and minor repairs to insure safe movement over the road between terminals, sending to the repair yard any bad-order cars that must be "shopped" for this purpose. After inspection and repairs have been completed, the train is prepared for switching from receiving yard to classification yard, which process requires car markers to chalk-mark cars for their respective classification tracks, according to destination and routing, also furnishing corresponding switching lists for the conductor in charge of switching crew, and switchmen who operate switches leading into the classification yard. Yard locomotives and a force of trainmen are required to switch trains into the classification yard at proper speed for accurate weighing at points where cars pass over a track scale; also requiring brakemen, commonly designated as "car droppers," to ride cars into the classification yard and control them by use of hand brakes to bring them to a stop at the proper point and to avoid damage by impact with preceding cars standing on track.

The train from receiving yard has now been distributed on various tracks in the classification yard, usually from ten to thirty tracks, depending on the size and importance of the yard operation. The original train having thus lost its identity, following trains, classified in like manner to the same tracks, are required to assemble cars that will comprise new trains to be dispatched when the required tonnage is accumulated. A variety of conditions arise at this stage of the operation that seriously influence the time consumed by cars enroute to their destination, which may necessarily be repeated from one to many times between the originating point and destination of cars, depending on the distance and the territory over which they are moving. The time required to assemble sufficient tonnage for a train in the classification yard is very largely dependent on the steady or intermittent arrival of trains in the receiving yard; also on the hauling capacity of road locomotives used on trains dispatched in the same direction, which may be 35 or 50 cars from one yard and 100 to 115 cars from another yard for the same class of locomotive, depending on the ruling grade of the division over which trains are being hauled.

In this connection another primary cause of delay in assembling trains in the classification yard is to be found in the usual number of classifications imposed upon certain yards for the convenience of connecting divisions to meet their requirements for various reasons, but primarily due to inadequate track and switching facilities. So-called "prior classifications" are also a source of yard delay at the point where they are assembled, but the time thus consumed is presumably offset by saving in time at the next yard or terminal point where such trains are kept intact and delivered to the division in advance thereof without reclassifying, which means an actual saving in the aggregate time consumed from shipping point to destination, also in operating expenses. Therefore a considerable portion of yard delay is beyond control, owing to prevailing conditions that cannot be eliminated. However, there is ample opportunity for minimizing yard and road delays to train movement by employing the best operating methods, maintaining sound organization and efficient supervision.

Time consumed assembling tonnage for heavy trains to be hauled by large types of locomotives over comparatively level grades may be viewed by some as a contributory cause of "avoidable waste in cars," but it should be recognized that doing so reduces the number of engine and train crews and locomotives required to haul a large volume of freight, which means economical operation.

C—The Inspection and Repair of Cars by the Maintenance-of-Equipment Department

When trains are hauled over the road certain defects develop, and by the time they reach the terminal of a run a certain portion of the cars, say 3 to 5 per cent, must go to shop for repairs. The cars from the time last inspected until they go to the industries or mines to be loaded and return, develop many defects due to stress and strain of service, and consequently they have to be shopped when reaching the nearest terminal.

There are three distinct classifications for shop cars: light, medium and heavy. When an inspector discovers a defect which he cannot correct, he applies a bad-order card, and places it in a conspicuous location on the car. These cards are placed in one of three positions: vertical, horizontal or at an angle of 45 deg. A card placed in a vertical position indicates light repairs; horizontal, heavy repairs; and at a 45-deg. angle, medium repairs.

After the train is inspected a car marker goes along the train and marks each car with chalk and the date and track number to which each particular car is to be classified.

As already stated, the classification yard consists of a number of tracks for the various classifications; a certain number of these tracks are set aside for shop cars, some tracks for light-repair cars, some for medium, and some for heavy repairs. The shop cars are moved from the classification yard to the car-repair yard by shifting engines, usually at night, and the repair tracks filled up so that when the gang foremen arrive at their places of duty approximately one-half hour in advance of the commencing time for the shop forces, they can prepare their work for the day. It is their duty to see that the work is properly distributed and there is sufficient material on hand to proceed with the repairs.

After they have all the cars written up they start inspecting the work done by the men to determine if it has been properly performed, and that proper charges for material have been made. After this is completed they report out such cars as are ready to go and mark those uncompleted to be set back. The shifting crew then takes out the entire string, returning those not completed. It is the gang foreman's duty to see that any cars not completed are in such shape that they can be moved out with the O. K. cars, as otherwise there would be non-movable cars between two or three cars O. K. for service and this would hold the cars ready for movement an unreasonable length of time.

After the cars are turned out of the repair shop they are returned to the receiving yard and reclassified over the hump to be returned to service.

In order to keep a check on cars undergoing repairs, a report is prepared and sent to the different operating officials. The report

indicates the time the car is shopped, the time it is moved to the shop, the time repairs are completed and the time car is moved out of shop. By checking over this report each morning the master mechanic, superintendent or general officers can determine in a few seconds if there are any cars that are being held an unreasonable length of time.

It is the aim of the operating officials not only to see that all cars are repaired, but to have the cars repaired promptly and returned to service in the most expeditious manner.

Conclusion

The great secret of the entire operation, therefore, lies in coöperation and teamwork, and these can be checked by suitable reports.

The statistics which reach the superintendent's desk giving hourly, daily, weekly and monthly information are many and varied, and originate from numerous sources, but the reports scanned by the author with most interest each day are those which tell where each of the heavy road freight and passenger engines were the day before and what they were doing. There is a maxim, "Take care of the shillings and the pounds will take care of themselves." It seems to apply particularly to the railroads. Take care of the engines and the dividends will take care of themselves. Of course this could not be literally true, but there is so much involved in this "taking care of the engines," embracing as it does the time and inferentially the money spent on locomotive repairs, the quality of back-shop and engine house work performed, the proper tonnage rating, and suitable loading of engines in order to obtain the most economical road speed, the reduction of delays getting into and out of yards, the inspection and repair of car equipment, the efficiency of water stations, coal-, sand- and ash-handling plants, the organization and operation of wreck forces, the handling of local freight and work trains, in fact, almost each and every one of the thousand and one matters that go to make up a successful operation of a division. If any one of the features named above is not functioning properly, as well as others too numerous to mention, the effect will be seen in the slowing down of the road speed or a lowering of the average mileage per serviceable locomotive or a falling off in the loading efficiency. All these must be at their highest possible levels of practical performance, and when they are, a glance of the eye at the daily barometer ought to tell it, and when they are not, a few minutes' inspection of the data ought to tell why and point the remedy. The supervisors must have tracks fit for speed and service; the signal engineer must have communicating systems and signal apparatus in good working order; the road foreman must have engines properly rated and sufficient crews and supervision; the train master must have his yard and road forces properly instructed and disciplined; the division operator must have his train dispatchers and signalmen alert and intelligent; and the master mechanic must produce the power in ample quantity and fit for service. If the division superintendent can be assured that everything is being done that can be done to have every available engine in service that can be put in service, and that every engine dispatched is being loaded to the maximum number of cars it can economically haul, then he is assured of an economical performance and an avoidance of waste in the operation both of locomotives and cars.

APPENDIX NO. 1

Daily Slow Freight-Train Performance Record

The record shown in Fig. 1 is prepared each morning from the train sheets and tonnage records of the previous day. Each dot or circle represents a train, its position vertically indicating on the scale at the left the percentage of the full capacity of the engine utilized, and its position across the sheet, read from the scale of hours at the bottom, shows the time the train crew was on duty. The red dots (shown in Fig. 1 as small circles) represent eastbound trains and the black dots westbound trains. The extreme left-hand dot shows a westbound train which was 99 per cent of the full adjusted-tonnage rating of the engine, and it made the run over the division in 8 hours 12 minutes from the time the crew were called to report for duty until they were relieved from duty at the opposite terminal. It includes initial and final terminal delay and this particular train made an excellent run, well within the overtime limit. The red dot (small circle) slightly above and to the right represents a 100 per cent eastbound train, 8 hours and 18 minutes from called to relieved. The dot to the extreme right shows a westbound 101 per cent train, 14 hours. It is seen at a glance that the lowest loading for that day was 94 per cent and the highest 105 per cent. The spread of the time was from 8 hours and 12 minutes to 14 hours. Fourteen runs were made within the overtime limit (of ten hours and a quarter), and no crews were relieved on account of the 16-hour law. The average of all the red dots (small circles) is shown by the red cross at A and its position shows that the average of all the eastbound trains that day were loaded to 100 per cent and the average time was 10½ hours. The black cross at B shows that the average loading of westbound trains was also 100 per cent and the time just under 11½ hours.

The black characters near the left-hand margin indicate the class of engine hauling the westbound trains, the number of cars being shown on the scale at the right, and the time from called to passing out of the yard being read on the scale of hours at the bottom. From this it can be seen that there were three trains of 100 cars each, 1 hour and 24 minutes, 1 hour and 30 minutes and 1 hour and 42 minutes getting out of the yard. There were nine trains of 115 cars each, varying from 1 hour and 12 minutes to 2 hours and 48 minutes initial terminal time. Other trains are as indicated, the total number completing their runs that day being 20. Similar information is shown for the eastbound trains by the red (dotted-line) characters near the right-hand margin, the final terminal delay being recorded from right to left and read on the scale just above; the number of cars per train varying from 90 to 105, and the time from 36 minutes to 2 hours and 6 minutes. The same sheet is also used to record fast freight trains, but these have been omitted to avoid complication. An explanation can be given on the back of any unusual conditions, undue length of time on the road, reason for relieving crews, etc. A code of symbol letters reduces the need of elaborate descriptions.

After keeping these daily sheets for several months, the location of all the red crosses may be recorded on a sheet of tracing cloth, or a composite of all the red dots (small circles) may be made on one tracing, and through the center of gravity of all the dots a curve may be drawn, and this will show for any point on the curve the average time for the trains corresponding to that tonnage loading. A similar composite of the black dots[1] will show the westbound trains. These curves are shown in Fig. 2 and are the basis of the calculations of the most economical train loading described in Appendix No. 2. Even if most of the dots and circles are concentrated along the lines of full tonnage, there will usually come days when engines are being loaded light to get them to the other end of the division to meet a heavy movement, and there are occasional mistakes of yard clerks which result in underloaded or overloaded trains which are not checked up until the conductor's wheel report is recorded at the end of the run.

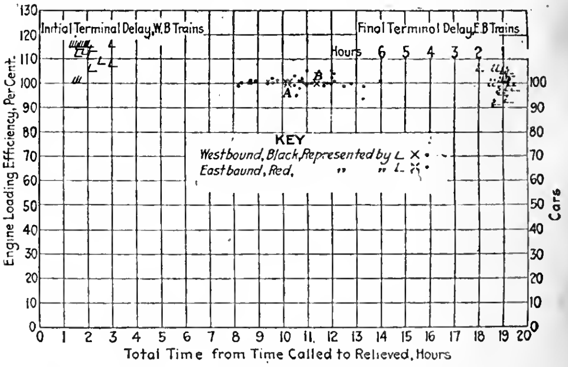

Fig. 1 Daily Slow Freight-Train Performance Record

APPENDIX NO. 2

The Most Economical Train Loading

The curves described in Appendix No. 1 having been prepared, the data shown in Table 1 may be calculated. Column 1 gives the percentage of engine loading, from 120 per cent down to 80 per cent. The average flat tons in the eastbound and westbound trains having been recorded each day on the sheets shown in Fig. 1 and the percentage of the engine loading being also available for each day, a summary may be run up at the end of the month and a comparison drawn as to the number of flat tons per train which would correspond to a 100 per cent tonnage train. A few months of this information will settle the proper figure and this has been shown for the westbound trains at the head of column 2. This amount multiplied by the percentages in column 1 gives the tons per train in column 2. From the load-time curves in Fig. 2 may be read the average time for a westbound train loaded to 120 per cent of the engine rating, etc., and these times recorded in column 3. The summary mentioned above will also show, by extension, the total gross tons moved each day, and the average of this figure is at the top of column 4. The number of trains which it would be

---

[1] It is suggested that black ink be used in making the composite of the red dots and red ink for the black dots. It is much easier to see the opposite color through the thickly clustering dots of the composite, and those below the tracing cloth will not be so readily missed.

[1] 2400 × (1) = 2400 multiplied by value in Column 1.

necessary to run to move the average day's business may be found by dividing this number of tons by the proposed tons per train in column 2 and the result recorded in column 4. The same process is followed to obtain the figure at the top of column 5 as explained for column 4 and as there will usually be the same number of eastbound as westbound trains in order to avoid running power and crews light, the tonnage per eastbound train will be found by dividing the total tons to be moved per day by the trains per day shown in column 4 and the results recorded in column 5. The total time on duty for the crews in making a round trip is shown in column 8, and from data obtained on reports described in other appendices, it has been determined that on the division under consideration, engines are off the road and in the hands of the Motive Power Department about 24 hours for every round trip they make. Consequently, 24 hours should be added to the times shown in column 8 to give the total time of an engine for a round trip as in column 9. This number of round trips made in column 4, multiplied by the number of hours per round trip in column 9 will give the total number of engine hours shown in column 10, and these figures, divided by 24 hours in the day, will give the number of engines assigned to the service as recorded in column 11.

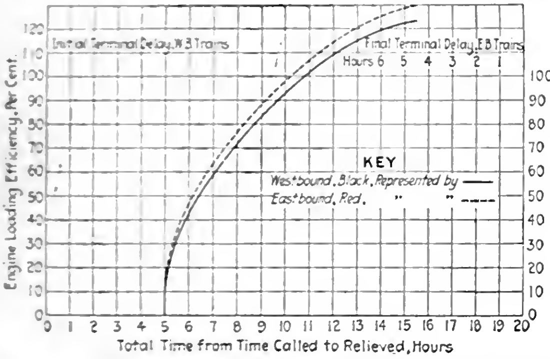

Fig. 2 Type of Curves Used to Show Average Time for Trains of a Given Tonnage Loading

As the average distance run by these trains is 128.2 miles and the overtime speed basis is now 12$^1/_2$ miles per hour, the time per trip is 10$^1/_4$ hours and for the round trip 20$^1/_2$ hours. Consequently, the overtime per round trip is found by subtracting 20$^1/_2$ from the times shown in column 8, and the result entered in column 12. We now pay time and a half for overtime in freight-train service, therefore the number of hours shown in column 12 multiplied by 1$^1/_2$ gives the overtime hours for which we have to pay at the regular hourly rates, and these figures are entered in column 13. Multiplying by the number of trains per day in column 4, we have the total number of punitive overtime hours per day shown in column 14. The total wages paid to the engine and train crews in slow freight service and with the class of engine under discussion now amounts to $3.975 per hour, and the figures in column 14 multiplied by this sum gives the total overtime cost per day as shown in column 15. The straight-time hours per day is the product of the 20$^1/_2$ hours for one round trip times the number of trips in column 4 and is shown in column 16. This at the rate of $3.975 per hour gives the total straight time cost per day shown in column 17, and adding the overtime cost in column 15 gives the total wages cost per day in column 18.

Modern Mikado locomotives of the size under consideration are worth $47,750 apiece, and taking interest at 6 per cent, depreciation at 4 per cent and insurance and taxes together at 1 per cent, we have fixed charges of $5,256 per locomotive per year, or $14.40 per day or 60 cents per hour. Column 19 shows the value of the engine hours in column 10 and the sum of the wages cost in column 18 gives the total engine and wage cost shown in column 20. It will be noted that this cost is a minimum at 100 per cent loading. The limits are rather narrow and an error of 10 per cent in overloading or underloading would cause a loss of $100 per day or $3000 per month on the amount of business handled on the division under consideration.

DISCUSSION AT RAILWAY SESSION

In opening the third session held so far by the Railway Division of the A.S.M.E. on Tuesday, December 6, 1921, Edwin B. Katte, chairman of the Division, called attention to the fact that the keynote of the Annual Meeting, the elimination of waste, was being carried out by the Division in papers relating to waste in connection with the design and operation of railway equipment. He introduced W. H. Winterrowd, chief mechanical engineer of the Canadian Pacific Railway, and now vice-chairman of the A.S.M.E. Division, who presided at the session. The papers presented were Avoidable Waste in the Operation of Locomotives and Cars, by William Elmer; Avoidable Waste of Locomotives as Affected by Their Design, by James Partington; and Avoidable Waste in Car Operation—The Container Car, by Walter C. Sanders.

Discussion of the Paper by William Elmer

Wm. L. Bean[1] opened the discussion of Mr. Elmer's paper, stating that he considered it a splendid exposition of the practical means for overcoming a loss incident to the short and inadequate use of equipment and that it presented a specific method of working out improvements. It had been his experience, he said, that locomotives which were operating satisfactorily to the extent of keeping off the delay sheet, might not be operating with satisfactory fuel economy. He had noticed on the N.Y.N.H. & H.R.R. during 1921 that the consumption of coal on a unit basis in freight service was 10 per cent less than the previous year. Part of this increase in economy was due to equality of loading, as in times of slack business trains could be uniformly loaded more easily than in busy times. He considered overloading of engines worse than underloading. He had found that many roads, in applying the adjustment factor explained by the author, failed to take account of the difference of its application on the level and on grades, as was also true of temperature adjustment, which applied, of course, only to rolling friction.

A. J. Wood[2] spoke of the importance of considering acceleration so essential in heavy passenger traffic. There was a field for development of this problem, he said. He had been interested to find how accurately schedule time can be computed by laying out speed-time curves from ordinary roadbed data.

Mr. Elmer, in closing the discussion, commented on a reference Mr. Bean had made to the importance of fuel economy, saying that he did not wish to imply that he did not consider this of importance. He would not, however, give too much attention to a slight variation in fuel economy if the loading of the locomotive were correct. Acceleration, too, was important, but was as vital in freight traffic as in passenger traffic.

Discussion of the Paper by James Partington

C. C. Trump[3] presented a written discussion in which he called attention to the application of the uniflow engine to locomotives. Prof. Johann Stumpf, by using the energy of exhaust steam with an ejector action, had been able to lower the back pressure in the cylinder by 4 or 5 lb. per sq. in., especially at heavier loads. Thus both the length and diameter of the uniflow cylinder for a given

---

[1] Assistant General Mechanical Superintendent, N.Y.N.H. & H.R.R.
[2] Professor of Railroad M.E., Pa. State College, State College, Pa.
[3] Fuller Lehigh Co., New York, N. Y.

drawbar pull had been reduced. In addition, a steadier draft had been attained. A smaller boiler is required but a larger superheater, because of reduced flue temperatures. Data from Europe indicate that with 700 to 800 lb. pressure in a compound uniflow engine, a well-designed condenser, economizer, etc., the economy and simplicity of a Diesel locomotive might be equaled, with the additional advantage of ability to use a greater variety of fuels.

Mr. Trump presented a translation of a paper by Professor Stumpf dealing with the subject of the uniflow locomotive with single-beat valves and exhaust ejector action.

Wm. H. Wood,[4] offered a written criticism in which he claimed that most of the devices for increasing the economy of locomotives, such as firebrick arches, feedwater heaters and superheaters, did not result in the economy claimed for them but in greater maintenance costs.

John L. Nicholson[5] called attention to the newly developed thermic siphon which had shown an average saving of 15 to 19 per cent in the fuel consumed per drawbar horsepower. If two thermic siphons were to be applied to locomotive No. 50,000, mentioned by the author, they would add approximately 62 sq. ft. to the radiant-heat-absorbing surface of the firebox, and result in an addition of 164 boiler horsepower to the capacity of the locomotive. Allowing for the net additional weight of the siphons, the result in this locomotive would be a reduction in weight per boiler horsepower from 119.6 lb. without the siphons to 113 lb. with the siphons.

W. F. Kiesel, Jr.,[6] called attention to the errors involved in using empirical formulas for steam requirements of locomotives. Thus comparison of the locomotives referred to in the first and second columns of the author's Table 1, which are the Erie No. 50,000 and the Pennsylvania K4S, respectively, show, according to the formulas, that the former is the more economical. Test results, however, are as follows:

	No. 50,000	K4S
Low rate, one test, coal, lb. per i.hp.	2.12	1.52
Low rate, one test, steam, lb. per i.hp.	16.5	14.96
Maximum i.hp.	2216	3184
Weight of locomotive in lb. per maximum i.hp.	121.4	97.0

This shows that the K4S is actually far ahead of the No. 50,000 on every count, instead of being inferior, as the comparison, based on the antiquated empirical formulas, would indicate.

Frans H. C. Coppus[7] wrote that the logical order of locomotive development, as far as combustion is concerned, should be the following:

1 Mechanical induced draft at front end
2 Condensing exhaust steam and returning condensate to tender
3 Pumping the hot water from the tender through a waste-steam and waste-gas heater into the boiler
4 Under-grate forced draft in the ashpan.

His discussion continued with an elaboration of these improvements and an estimate of the savings to be expected from their use. He looked forward, he said, to a reduction of the operating expense of a locomotive equivalent to 50 per cent of the present coal consumption. The suggested improvements, he pointed out, can be attached to all locomotives now in use and at a cost which will pay for them within a year.

John E. Muhlfeld[8] contributed a written discussion in which he developed some ideas in addition to those presented by the author, such as increased boiler pressure and superheat, compounding, reduction of the factor of adhesion, and tender boosters. He also pointed out that it would take a locomotive of considerably increased fuel economy to make worth while the scrapping of many serviceable obsolete locomotives now in use.

Carl J. Mellin[9] said that some of the formulas presented by the author should be accepted only as approximations.

Elmer A. Sperry[10] spoke of the possibilities of economy in railroad operation by the use of Diesel-engine locomotives. The possibility of using bunker oil as fuel in the new compound Diesel engine instead of the high-grade oil which the present Diesel required was going to be greatly in favor of this new type of power. It was possible, he said, that the Diesel locomotive would be combined with electric motors, to obtain the advantages of electric power and economical generation of current.

Oliver C. Cromwell[11] called attention to faulty design in providing sufficient lubrication for the locomotive trucks. He had found less packing used on the locomotive journals than on those of tender and trailer trucks.

Discussion of Paper by Walter C. Sanders

A. E. Ostrander[12] wrote that special containers for use in the transportation of high-grade freight are not new; they have been in successful operation for years. One large company in New York has purchased several lots of containers called "steel lift vans," and their method of operation is to supply one of these vans to a shipper, furnishing him with keys to special locks with which the containers are fitted. The shipper then loads his freight into the container, the lading in this case being high-grade furniture, locks it up and it is then delivered to the railroad for shipment to any part of the world.

The fact that they have continued in business, and, as indicated above, have purchased several orders of the vans, shows that it must have been profitable business for them; therefore it would certainly seem to be more profitable to a railroad to handle strictly high-grade freight in this manner.

In regard to the statement made that the use of the container car saves demurrage on freight cars, this seems unfair to the railroad if no charge is made for demurrage on the containers themselves. In other words, the shipper or the consignee has no more right to use a container as a storage warehouse than he has to hold up a car for the same purpose when he is not in a position to unload his goods.

Verbal discussion of the paper was participated in by V. N. Crocker, Supt. Mail Traffic, N.Y.C.R.R.; C. H. Otis, Asst. Supt. of Car Construction, N.Y.C.R.R.; R. H. R. Newcomb, Asst. to President, B.&M.R.R.; and F. S. Gallagher, Engr. of Rolling Stock, N.Y.C.R.R.; in which the advantages of the container car and experiences with it were brought out.

Bureau of Economic Research

This Bureau was organized for the purpose of finding and placing the facts in regard to economic questions before the public. In order to ensure the impartial and scientific treatment of the data, its Board of Directors is composed of men of widely divergent points of view.

The directors include Edwin F. Gay, President; John P. Frey, Vice-President; W. C. Mitchell, Director of Research. The Research Staff is composed of: Wesley C. Mitchell, Willford I. King, Frederick R. Macaulay, and Oswald W. Knauth.

How large is the National Income? Is it keeping pace with the growth of population? By what industries is it mainly produced? How is it distributed among our income receivers? These are the questions to which an answer is given in the report of the National Bureau of Economic Research of New York entitled "Income in the United States," which is now in press, and to be issued within a few days.

The total National Income increased very greatly between 1910 and 1919 when measured in current dollars; it increased less when calculated in unchanging dollars based on 1913 prices; the per capita income in terms of 1913 dollars increased still less.

The time-honored opinion that America is a nation of spendthrifts is brought into question by the report. The savings of individuals going into extension of plant as represented by new corporate issues of securities; public improvements financed by state and municipal bond issues; and the great number of private houses built each year; all these mount up to a large total.

Emergency Fleet Corporation Water-Tube Boilers for Wood Ships

By F. W. Dean,[1] Boston, Mass.

Tests upon the standard four-pass water-tube marine boiler designed by the United States Shipping Board Emergency Fleet Corporation, using coal as fuel, were reported by the present author and Mr. H. Kreisinger in a paper read at the Annual Meeting of the Society in 1919. In consequence of the introduction of oil for fuel on many of the steamships of the United States Shipping Board, it became desirable to ascertain the relative merits on several of the available mechanical atomizing oil burners for boilers. Tests were accordingly run, the boiler used having a heating surface of 2518 sq. ft., a furnace volume of 408 cu. ft., and a commercial horsepower of 435 on the basis of the marine rating of 6 lb. of water to a square foot of heating surface per hour. These tests and the results obtained form the subject of the present paper.

OIL-FUEL EVAPORATIVE TESTS

In the paper presented to this Society in 1919 by the author and Mr. Henry Kreisinger, on coal-fuel tests of Emergency Fleet Corporation water-tube boilers for wood ships,[2] it was stated that oil-fuel tests were being made, and in the present paper the principal results of those tests are given.

In consequence of the introduction of oil for fuel on many of the steamships belonging to the United States Shipping Board it became desirable to ascertain the relative merits of several of the mechanical atomizing oil burners for boilers. The tests were made under the direction of the writer assisted by Mr. Henry Kreisinger, then Fuel Engineer of the Bureau of Mines, and under the critical observation of Lieut-Commander W. R. Purnell and Lieutenant Pennycook from the Philadelphia Fuel Oil Testing Plant of the U. S. Navy. As in the coal-burning tests, assistants for chemical and physical work were furnished by the Bureau of Mines, as well as by the Emergency Fleet Corporation.

The boiler tested was the four-pass boiler illustrated on p. 627 of the former paper and here reproduced as Fig. 1. In the oil tests the bottom of the casing was dropped 12 in., and the furnace on sides and bottom was lined with brickwork about 12 in. thick, there being $2^1/_2$ in. of sil-o-cel brick next to the casing. These were covered by $2^1/_2$ in. of calcined brick. The sides were still further lined with firebrick 6 in. thick and the bottom covered with two courses of standard firebrick laid flat. This formed a very effective insulation, so good, in fact, that the bricks suffered accordingly. However, it was the standard lining of the Emergency Fleet and was very satisfactory in keeping down the temperature of the fire rooms aboard ship, for which purpose it was adopted. This is shown in Fig. 2.

The furnace volume was very small, the distance between the front and back walls was only 6 ft., and the distance from the back wall to the burner tip about 6 ft. 9 in. This short distance, without doubt, prevented the atomizing capacities of the burners from being fully developed. After every series of tests the joints between the bricks opposite each burner required pointing and sometimes the bricks over a small area required replacing.

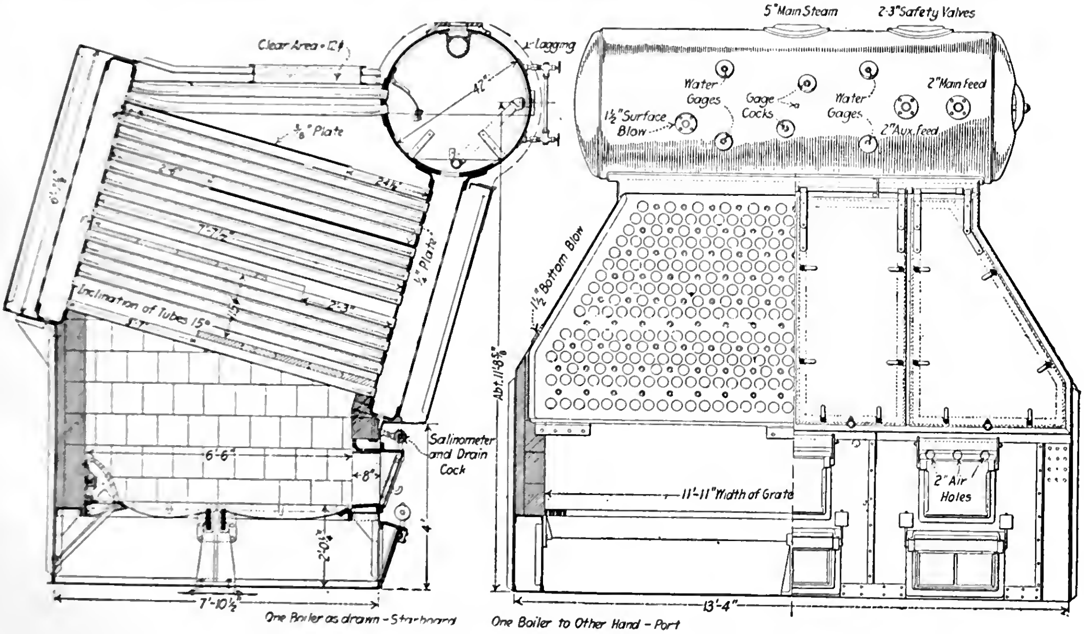

Fig. 1 Four-Pass Standard Water-Tube Marine Boiler for Wood Ships

The following were the dimensions of the firebox below the tubes

Height of furnace at front	5 ft. 0½ in.
Height of furnace at back	6 ft. 9 in.
Width of furnace	11 ft. 6½ in.
Distance between front and back walls	6 ft. 0 in.
Volume of furnace	408 cu. ft.

The boiler was equipped with thermocouples for measuring the temperatures of the gases throughout the passes and in the uptake. At the latter level there were several thermocouples for determining the temperatures at various points, for it had been previously ascertained that the temperatures in the different parts of one horizontal plane of the uptake were not uniform and varied as much as 100 deg. fahr.

Means were provided for sampling the gases at various points throughout the boiler between the vicinity of the burners and the

Presented at the Annual Meeting, New York, December 5 to 9, 1921, of The American Society of Mechanical Engineers. Slightly abridged. All papers are subject to revision.

[2] Trans. Am.Soc.M.E., vol. 41, p. 623.

uptake. Thus the progression of the process of combustion could be ascertained. Similarly draft gages were arranged to indicate the drafts at various points.

Some of the dimensions of the boiler are given as follows:

Width of casing at floor level	13 ft. 4 in.
Length of casing at floor level	7 ft. 10½ in.
Height of center of steam drum above floor	11 ft. 8⅝ in.
Width of water spaces in headers	8 in.
Outside diameter of tubes	3 in.
Exposed length of tubes between headers	7 ft. 7½ in.
Number of tubes connecting headers	388
Number of tubes between rear header and drum	21
Steam pressure carried	210 lb.

The Oil

Mexican oil was used because it is the only oil that is usually available for steamship fuel. This oil as it comes from the wells is of about 21 gravity Baumé. About 12 per cent to 13 per cent of gasoline is removed, leaving the oil at about 16 gravity Baumé. The heating value per pound is about 18,330 B.t.u.

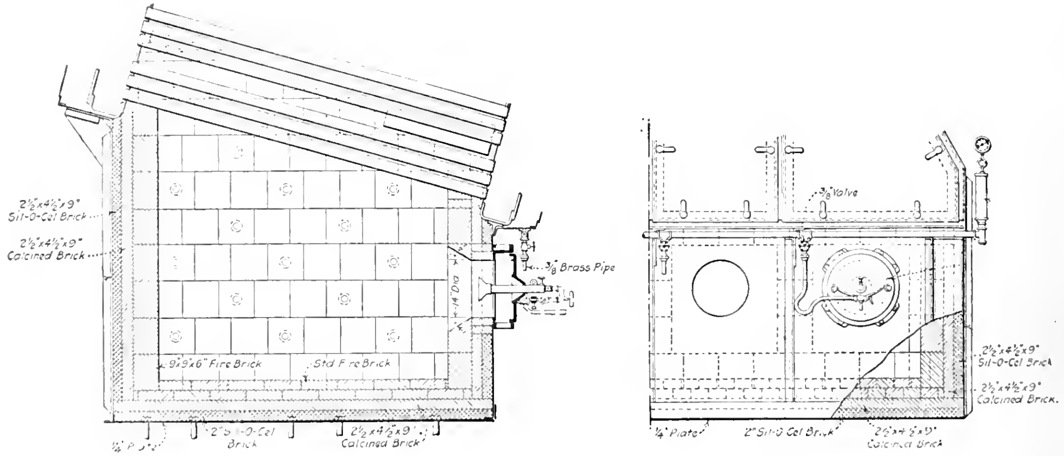

Fig. 2 Arrangement of Furnace of Boiler for Oil Firing

The first sample taken was found by the Bureau of Mines to have the following properties:

Specific gravity at 15 deg. cent	0.960
Gravity, Baumé, modulus 140, at 60 deg. fahr	15.8
Viscosity, Engler, at 65.5 deg. cent	19.21
Calories per gram	10,179
British thermal units per pound	18,323
Water, per cent	0.00
Sulphur, per cent	3.88
Mineral matter, sand, etc., per cent	0.00
Flash point (Pensky-Martens closed tester)	72 deg. cent.
Burning point (Pensky-Martens tester opened)	116 deg. cent.
Solid at	−2 deg. cent.

Other samples, of which many were taken, differed but slightly from this.

The Burners

As stated before, all burners tested were mechanical atomizing. This type is used at sea in order that all steam used in heating the oil may be condensed and saved for feedwater.

Six kinds of burners were used, No. 1 being the U. S. Navy Bureau (of Steam Engineering) Standard Register Burner.

Other Apparatus

The oil was supplied to the burners by either of two horizontal duplex pumps, $5^1/_4$ in. by $3^1/_2$ in. by 5 in. A pair of suction and a pair of discharge oil strainers and an oil heater were loaned by the Schutte and Koerting Company. On the discharge pipe of the oil pumps there was a 6-in. air chamber about eight feet high, which maintained the oil pressure at the burners sufficiently steady for the best results. This chamber was emptied of oil at the beginning of each test and charged with air at 100 lb. pressure.

The oil was heated in the railroad-car tank and forced by air pressure into the weighing tank. From this tank the oil after being weighed was discharged into a tank containing a steam coil, and to this tank the pump suctions were connected. Between the pumps and suction tank the suction strainer was located and the discharge strainer was placed between the pumps and oil heater.

The Navy Bureau Standard Burner

This burner is shown in Fig. 3, and consists of a circular cast-iron register with inclined (not radial) blades around the outside between two thin narrow rings with which they are cast, so formed that the air passes between them somewhat toward the center of the burner, and by them is given rotation.

The register is suitably bolted to the boiler front, but between it and the front there is a conical ring which serves to direct the air toward the oil and counteract the opposite tendency caused by the centrifugal effect of the register.

The oil is forced through a pipe to the so-called tip, which is screwed on the pipe and serves the purpose of delivering the oil to the furnace in a rapidly rotating stream passing through a very small hole. The tip consists of two hardened steel parts, the outer one being called the "nut," and apparent on the drawing. The nut has a conical cavity with the apex toward the furnace and the other part is conical and fits it in firm contact. The latter is provided with tangential grooves fed by small holes and these grooves serve to rotate the oil as above mentioned.

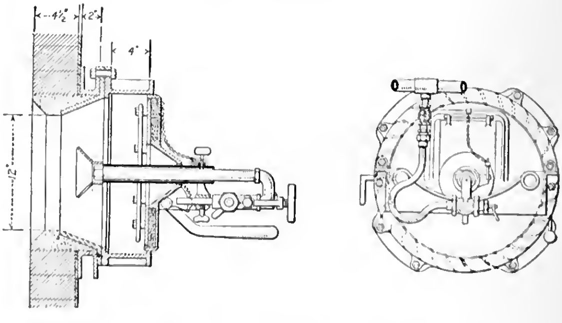

Fig. 3 The Navy Bureau Standard Burner

The centrifugal force derived from the rotation of the oil causes the latter to spread into the form of a thin hollow cone, which is protected from the inrushing air from the register by a cast-iron cone until it reaches an advisable thinness at the edge of the cone, where it is met by the rotating air with which it is thoroughly mixed. Immediately beyond this line of mixture the ignition occurs and the completeness of combustion depends upon the ade-

quacy of the quantity of air, the completeness of the atomization of the oil, and the thoroughness of the mixing.

The other burners have tips that rotate the oil, as this is indispensable in thinning the oil film, but burner No. 4 rotates the air but little, and No. 6 not at all. This demonstrates that the rotation of the air is not necessary, a conclusion that might otherwise have been reached.

THE TESTS

Four burners of each kind were applied to the boiler, and, except the Navy Bureau Standard burner, were placed with their centers 30 in. apart and 20 in. above the furnace floor, leaving 24 in. between the side walls of the furnace and centers of the adjacent burners. In some of the tests the Bureau burners were arranged likewise, but at the beginning they were placed with their centers 36 in. apart and 22 in. above the furnace floor, leaving 15 in. between the side-burner centers and the walls. No advantage in either spacing could be discerned.

The first burner to be used was the Bureau, and on account of inexperience with Mexican oil very poor results were for some time obtained and immense amounts of smoke made. With more experience excellent results were obtained and there was no difficulty in preventing smoke with this or any burner. In general a slight amount of smoke was allowed.

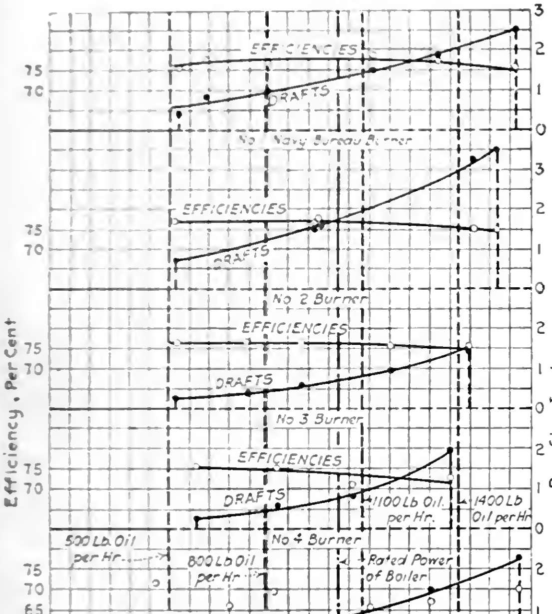

FIG. 4 EFFICIENCIES AND DRAFTS OF SELECTED TESTS

At the beginning there was frequent difficulty from the carbonizing of the oil, but this was gradually overcome.

The criteria by which the merits of a burner can be judged when used with induced draft are its ability to burn the oil to CO_2, to do this with a minimum of draft, to produce little smoke, to produce no carbonization in the burner, and to have sufficient range in oil-burning capacity.

To produce desirable CO_2 the oil atomization must be well performed and the air admitted in such a manner that it will intimately mix with the oil.

A common feature of all the mechanical atomizers tested is the rapid rotation of the oil as it enters the furnace, as in the Bureau burner. This is produced, as in that case, by forcing it at high pressure through small channels of various forms tangential to a small central hole in the burner tip through which it passes to the furnace. As it issues it rotates rapidly and the centrifugal force expands it and forms a thin conical shell of oil. While expanding it is usually protected from the incoming air by a thin cast-iron conical shell of advisable diameter placed in front of it with its base toward the furnace. When the oil reaches the edge of the cone it is swept by the incoming air and the mixing and ignition occur.

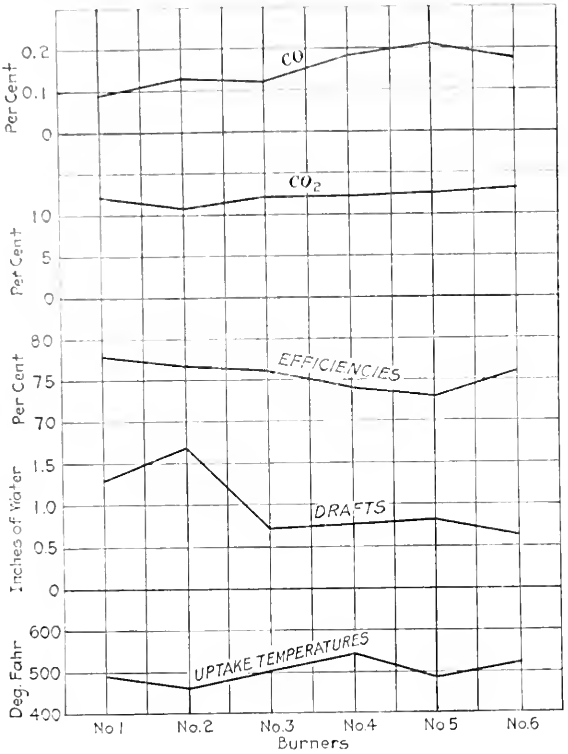

FIG. 5 COMPARISON OF BOILER EFFICIENCIES, DRAFTS, CO_2 AND UPTAKE TEMPERATURES AT RATED POWER OF BOILER WITH DIFFERENT BURNERS, AND AVERAGE CO OF SELECTED TESTS

RESULTS OF THE TESTS

The results of the tests which are considered to be most reliable and to represent the merits of the burners are given in four tables in the complete paper, of which Table 1 is representative. With each burner several preliminary tests were made before sufficient skill was acquired to obtain consistent results, and these are omitted. It may be well to remark here that the representatives of the burners were not able to operate them successfully, which indicates that the efficiencies of boilers with oil fuel are very uncertain.

It was intended with each kind of burner to consume oil at four different hourly rates for four burners collectively, namely, 500 lb., 800 lb., 1100 lb., and 1400 lb., but it was impossible to realize these results with precision.

In judging the merits of a burner by the magnitudes of the CO_2 and CO, a difficulty is encountered from the fact that these constituents are not uniformly distributed throughout the area in which they are determined, whether it is in the uptake or in one of the passes.

Usually, in the boiler tested, the combustion is complete by the time the gases reach the first or lowest pass of the boiler, but if the gases are sampled in this pass they are far from uniform at different

points between the end of the baffle and rear header. The following are examples:

Test No.	CO_2 5 in. from header per cent	CO_2 17 in. from header per cent	CO_2 39 in. from header per cent
41	10.6	10.4	11.1
42	11.9	14.2	14.3
43	10.0	12.3	12.6
44	11.9	13.3	13.6
45	11.6	—	13.6
46	12.6	12.8	12.9

While the above are at different distances from the end of the baffle, the following are at the same distance and at different points in a line parallel to the end of the baffle and 19 in. therefrom:

Test No.	Position C CO_2 per cent	Position D CO_2 per cent	Position E CO_2 per cent
26	11	12	12.3
36	12.9	9.5	11.8

Similarly the other ingredients of the gases vary.

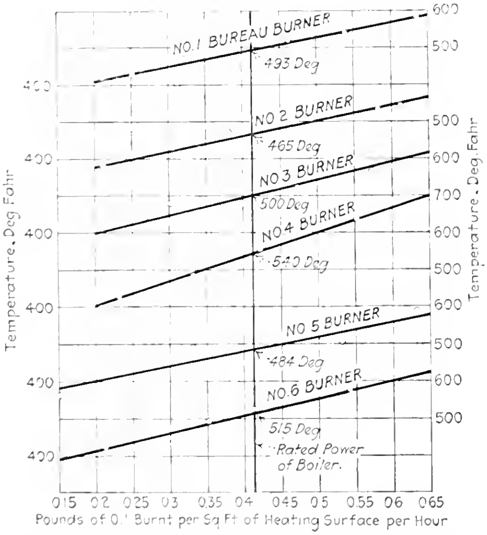

Fig. 6 Temperature Gradients for Different Rates of Oil Consumption with Different Burners

This variation of the gases of combustion renders it difficult to apply the chemical criterion in determining merits of a burner. In operating burners, of course, constant studies of the gas analyses are made, and this is necessary, for if the CO_2 is good at one point it is probable that it is at others. Nevertheless, it is necessary to determine the efficiency of the boiler under the same conditions as a final means of judging of the performance of a burner. It may be found that the maximum boiler efficiency will not correspond with the maximum CO_2, and this is true with these tests.

In the tables of results given the following efficiencies and average CO_2 and CO occur, and are here listed in the order of the burner trials.

Burner	Average efficiencies, per cent	Average CO_2 per cent	Average CO per cent
No. 1	77.02	11.88	0.09
No. 3	75.94	12.16	1.12
No. 4	73.50	12.00	1.18
No. 6	75.10	12.71	0.18

In Fig. 4 the efficiencies and drafts of the various burners are plotted. The Bureau Standard burner required more draft than the others. The reason for this is that it was designed for use on war vessels and made to require a strong draft, or fire-room pressure, in order not to backfire from gun shock.

In Fig. 5 a diagram of comparative uptake temperatures, drafts, efficiencies, CO_2 and CO is given.

In Fig. 6 the uptake temperature gradients of the different burners are shown. It will be noticed that the burner of lowest efficiency gave the steepest gradient. In Figs. 4, 5, and 6 all burners are included.

Burner No. 6 required the least draft and the least adjusting. It was the only burner that did not vibrate; it gave the highest CO_2, but also next to the highest CO. All other burners required constant adjusting to maintain proper CO_2, and the reason for this could not be ascertained.

DISCUSSION

IN the discussion which followed Mr. Dean's paper, Past-President D. S. Jacobus presiding, Joseph Nelis, Jr.,[1] who had been associated with the author in the early part of the tests, said, in reply to questions, that an attempt was made with the standard size adopted to run up to as high a capacity as possible—higher than they would be on shipboard—and that in some of the higher ratings the brickwork melted. The burners employed were all mechanical

Motion Pictures of a Stoker Furnace in Operation

By R. SANFORD RILEY,[1] WORCESTER, MASS.

THE moving-picture method of showing furnace operation is the result of about ten years of study and experiment in an effort to show continuously the action of a fuel bed. The opportunity thus offered of studying the fuel bed in operation may suggest new lines of investigation and development. The first intimate contact with a roaring-hot stoker fire usually developed the fact that motion-picture cameras were valuable and must be treated with more respect. A temperature approaching 3000 deg. fahr. presented new problems even to the most versatile motion-picture expert.

These difficulties in the observation of the phenomenon of the combustion of coal were finally overcome by the ingenuity and persistence of F. H. Daniels[2] so it is to him we owe the invention and accomplishment here described.

The camera (Fig. 1) was mounted at the right height on a stand which was arranged to roll up to the door. A heavy asbestos shield was built to protect the front and side of the camera. The shield over the front was made to fit more or less accurately in place of the door, while the shield at the side was made to protect the camera against the hot brick lining of the door when the latter swung open. This arrangement made it convenient to run the camera up into position as soon as the door was opened and maintain the furnace conditions the same as when the door was shut. Fig. 1 shows the operator in position with the door opening closed by the front shield and the hot door lining covered by the side shield shown. Even with these precautions, an electric fan was required to keep the camera safe and the operator less uncomfortable.

Fig. 1 Arrangement of Camera before Furnace Door

Of course, the real problem was the protection of the camera lens during the time it had to be exposed. The hole allowing the camera lens to look through the front screen was normally closed by another asbestos plate. This plate was tripped open by the operator's foot only during the time pictures were to be taken. Note the pedal and pulley connections thereto in Fig. 1.

For protection of the camera lens, a water cell with glass windows was first tried. A forced circulation of water through the cell did not prevent the glass from cracking. This defect was remedied by using special Pyrex glass, but it was found that air bubbles were formed on the side next the fire and even distilled water did not prevent them. These of course spoiled the clearness of the pictures. Finally, the combination of two sheets of heat-resisting glass with a thin sheet of gold between was tried. The gold acted as a mirror and threw back into the furnace approximately 75 per cent of the radiant heat, while it allowed approximately 75 per cent of the light rays to pass through. This protector for the lens was itself protected by two jets of compressed air arranged to impinge and mushroom in front of the opening in the asbestos screen. (See the hose connection in Fig. 1.) This air had to be delivered at approximately 100 lb. pressure in order to get the required cooling effect. Furthermore, it had to be clean and free from all moisture and oil. The trap shown underneath the camera was drained frequently in order to insure clean air.

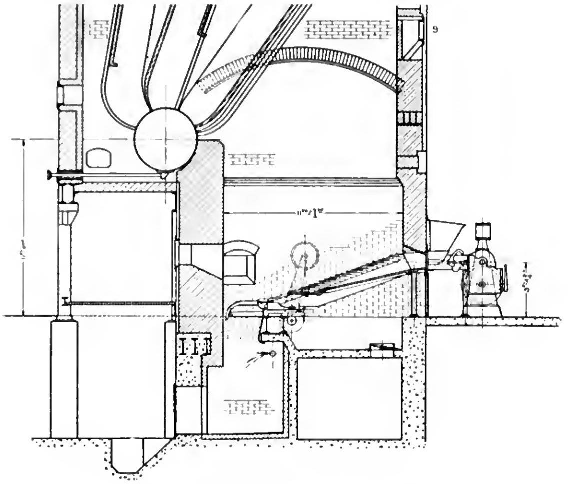

Fig. 2 Cross-Section of Furnace Setting

In addition to the screening effect of the gold leaf, it was found necessary to use what is called a Wrattan filter in order to prevent halations on the film.

At the suggestion of John A. Stevens, Mem.Am.Soc.M.E., a spectrometer was used in the fire and this showed a complete spectrum from reds down to violet and a brilliant yellow sodium line. The blues and purples increase in intensity, depending on the temperature of the fire viewed through the spectrometer. A panchromatic film stock was used to bring out the reds of the spectrum. This combination of gold screen, Wrattan filter and panchromatic film shows the texture of the fire well enough for the purpose.

The pictures were taken at the plant of Bird & Son, Inc., East Walpole, Mass. The boiler is a Stirling, of 822 hp., equipped with a 9-retort extra long Riley underfeed stoker. This installation was made by John A. Stevens, Engineer, of Lowell, Mass. and a cross-section of the furnace setting is shown in Fig. 2. The height of the mud drum being 11 ft. above the floor line allowed the use of the rear door shown in addition to the usual side observation door. Both these doors were used for taking pictures and proved just as convenient for this as they are for observation in everyday use.

Fig. 3 is a typical view through the rear door and Fig. 4 through the side door. Restriction of the view due to limited flare of the brickwork around the doors is a handicap but does not interfere with a study of the limited area seen. It is hoped later to get more extended views through specially flared door openings, but in this

Remarks accompanying presentation of motion pictures, under auspices of the Fuel Division, December 8, 1921, at the Annual Meeting of The American Society of Mechanical Engineers.

case it was necessary to take pictures under usual service conditions. It is also planned to make special studies of side-wall clinker action, and development of clinkers elsewhere in the furnace. The operating conditions were normal during the week these pictures were taken. It took nearly an entire week to get satisfactory motion pictures of the fire alone, and altogether about 2000 ft. of film were used up in order to get the 700 ft. shown. There was no attempt made to have the fire in any special condition. The pictures were taken generally as the apparatus could be prepared for action, and some of the operation shown is better as an example of what not to do.

The pictures taken and reproduced at normal camera speed show nothing much more interesting than the still pictures reproduced in Figs. 3 and 4, except perhaps the pictures of the banked fire and the dumping. The change from banked fire to 300 per cent of rating in six minutes is less monotonous than normal operation and shows quite clearly what happens in breaking up a fire bed that has been standing overnight. The dumping shows what happens if stokers of this type are dumped with a heavy fuel bed.

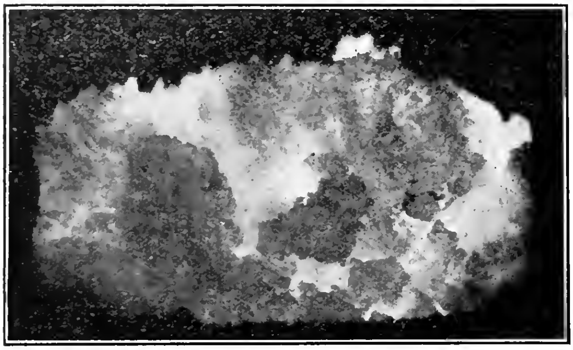

Fig. 3 Typical View through Rear Door of Furnace

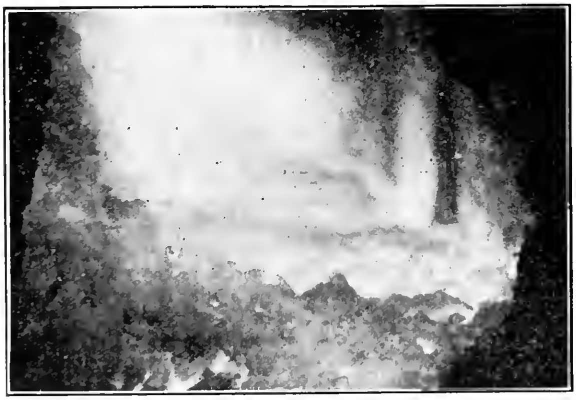

Fig. 4 Typical View through Side Door of Furnace

The most interesting features, and certainly the most dramatic, are those taken at intervals and speeded up like the well-known pictures of a growing plant, though of course no such great magnification of speed was used. Some of the pictures were taken at intervals of six and eight seconds. These show some appreciable change in the fire and when speeded up to normal reproduction rate of sixteen per second, there is an action worth watching. Particular attention will be called to some of these highly speeded-up pictures where the fuel bed appears to be "shimmying" on its way instead of "inching" along at a scarcely perceptible rate. The disintegration and melting away of the fuel is clearly shown as is also the gradual segregation of the non-combustible matter in the form of clinkers on the surface. It is to be regretted that there appears to be no way of getting a cross-section of the fire, although we hope to find a way of making some additional observations below the surface.

DISCUSSION ON E. F. C. WATER-TUBE BOILERS FOR WOOD SHIPS

(Continued from page 102)

atomizing burners, as steam atomizers wasted too much make-up water. Up to the ratings possible in marine work—4.5 to 6 lb. of evaporation per square foot of heating surface—smokeless operation was possible with oil at the proper temperature and pressure.

John A. Stevens[2] gave interesting particulars of the oil-burning installation on the Cunard liner *Mauretania*, describing the periscopes on the uptakes for observing the character of smoke passing, the foamite tanks for use in extinguishing oil fires, etc. The furnaces on the *Mauretania* were somewhat small—46 in. in diameter—and the combustion chamber restricted. The installation made it possible to dispense with 450 firemen and coal trimmers.

F. W. Leahy[3] called attention to the electric-drive vessels of the U. S. Shipping Board, which were provided with oil-burning Scotch boilers and all of the improvements that had been mentioned in connection with the *Mauretania*.

N. E. Lewis[4] gave particulars regarding the dimensions of a 450-hp. water-tube boiler with 4-in. tubes 14 ft. long and equipped for oil burning, as well as of a 2-in.-tube marine-type boiler. The efficiencies reported were perceptibly higher than those given in the paper. Mr. Lewis said that he had noted a statement in the paper that the efficiencies of boilers with oil fuel are very uncertain. He believed that a well-designed mechanical oil burner would give higher efficiencies with less care and manipulation on the part of the operator than any other fuel-burning apparatus. The adjustment of air and oil pressures was practically all that one had to watch, other than seeing that the burners were kept free, and it was not like the coal-fired, gas-fired, or other kind of boiler where several other elements entered into the operation.

Superpower

There are few who understand the superpower plan in detail, but the public does not understand it in general.

Even men in the business regard it as a collection of extra-large power houses and say that the superpower station of yesterday is the ordinary plant of today.

Perhaps they make a difference between the superpower station and the superpower plan, although they mingle them in writing and in conversation.

Look over an industrial city block of a few years ago. There are in it a dozen or twenty separate power plants. On the back street several small industries, each with its boiler and engine, coal carts from different dealers backing up and leaving the fuel, a ton or two at a time. Oil, packing and supplies bought in driblets. No one of them big enough to support a real engineer. On the main street some office buildings with more pretentious and efficient power plants, but the aggregate employing many more men than were needed, burning more fuel and paying more for their supplies than would be necessary in a well-designed and operated plant that could furnish not only power, but light, heat, hot and cold water, compressed air, vacuum, refrigeration, etc., to the entire block.

Extend this idealization to a section of the country instead of to a city block, and you have a conception of the superpower plan.

Only the superpower plan does not contemplate merely building a single immense power station for each industrial block or district and tying them all together. It proposes an intelligent engineering study of the power needs and the available sources of power supply for a district and a combination and coördination that will give to each subdivision of the district a dependable supply of power in the cheapest and most economical way.

It is the organization, the systemizing, the rationalizing of the power resources of the country.

And it is time that somebody began to think of power in that way; to look ahead to the time when the world will have to decide the purposes for which fuel may be burned and power used; to pick the essential industries. This time is already in sight so far as liquid fuels are concerned.—F. R. Low, Mem.Am.Soc.M.E., in *Power*, Jan. 10, 1922.

A Study of the Elastic Properties of Small-Size Wire Cable

By R. R. MOORE,[1] DAYTON, OHIO

In aircraft work use is made of several varieties of small-diameter steel cable, knowledge of the physical characteristics of which is important for efficient design. The present paper gives results of a series of tests carried out at McCook Field, Dayton, Ohio, in which it is shown that the modulus of elasticity of small-sized wire aircraft cable varies from 15,000,000 to 28,000,000, depending upon the size and type of the cable. The maximum difference between moduli of specimens of the same size and type of cable may be as high as 3,000,000.

It was also found that the modulus of elasticity may be raised by loading the cable below the elastic limit, and that resting the cable does not seem to have any definite effect on the modulus. The elastic limit may be raised by loading the cable a little beyond this point, the maximum increase obtained amounting to 63 per cent of the original elastic limit.

THE development of aircraft has brought into use several varieties of small-diameter steel cable, a knowledge of the physical characteristics of which is important for efficient design. Such information becomes vitally important to engineers who are concerned with the development of new types of aircraft and the advancement of the science of aviation in general. This is the case at the Engineering Division of the Air Service, located at McCook Field, Dayton, Ohio. The subject was first brought to the attention of the Material Section by a request from the Design Section for stress-strain curves on various sizes of the 19-wire non-flexible type of aircraft cable. After completing these tests the investigation was extended to cover all the available types of cable used in airplane construction.

Engineering handbooks do not quote any value for the elastic limit of wire cable, and for the modulus of elasticity they give a value of about 12,000,000. This value, however, refers to wire ropes with hemp centers and for sizes greater than $^3/_8$ in. In aircraft work we are mostly concerned with ropes made of high-strength steel wire in sizes less than $^3/_8$ in. and types which have either a wire or wire-strand center. The value for the modulus of this type of cable is considerably greater than 12,000,000.

While the determination of ultimate strength is a comparatively simple matter, the accurate measurement of elongation necessary in determining the elastic limit and modulus of elasticity presents several difficulties. In the first place, the fact that the cable is built up of so many small wires and strands makes it difficult to locate accurately a definite gage point and attach an instrument there without its shifting in position. It is evident that the usual type of extensometer with pointed screws for grips is of no use for this work. In the second place, a cable twists when under load, so that any rigid instrument cannot be used.

Tests were made on a 20,000-lb. Olsen structural-material and airplane-parts testing machine which was previously calibrated and found to be in good adjustment. However, in several cases the measurement of load was obtained from the deflection of an accurately calibrated spring placed on the upper head of the machine and arranged so as to take the load applied to the cable. The deflection of the spring was measured with an Ames dial reading to 0.001 in. It was found that this method gave more consistent results because it was considerably more sensitive to small variations in load than the lever system of the testing machine. In fact, some such arrangement is absolutely necessary in testing the small cables, particularly the $^1/_{32}$, $^1/_{16}$, and $^3/_{32}$-in. sizes, in order to obtain the elastic limit and modulus with any degree of accuracy. To obtain the breaking load, however, the spring must be removed and the load measured on the machine. A view of the complete set-up with extensometer attached is shown in Fig. 1.

The instrument used was very similar to the familar wire-wound dial type of extensometer. The greatest difficulty was in attaching the dial to the cable at the gage point. This was accomplished by attaching the dial to a specially devised clamp as shown in Fig. 2. At the other gage point, a second clamp was attached similar to the one holding the dial. To this clamp one end of a fine magnet wire was attached; the wire extended down the cable and around the brass drum, the loose end having a light weight attached to it. It is clear, then, that as the two gage points moved apart the wire turned the drum and shaft upon which the needle was mounted, thus recording directly on the dial the elongation of the cable.

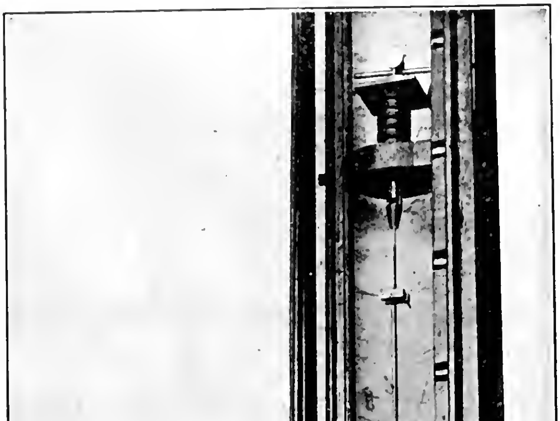

FIG. 1 COMPLETE SET-UP OF APPARATUS WITH EXTENSOMETER ATTACHED

In order to reduce the error occurring from this twisting, the wire was placed as near the cable as possible and hardly exceeded $^1/_2$ in. from the center of the cable at any time. As the maximum twist noted did not exceed 90 deg., the error incurred in the modulus due to this error of elongation is negligible.

Cables of four different types of construction and one made of phosphor-bronze wire were tested, the types and sizes tested being given in Table 1.

A chemical analysis of several wires taken from the phosphor-bronze cable gave the following composition: tin, 3.77; copper,

---

[1] Chief, Physical Testing Branch, Material Section, McCook Field.

Abstract of paper presented at the Annual Meeting, New York, December, 1921, of THE AMERICAN SOCIETY OF MECHANICAL ENGINEERS. All papers are subject to revision.

95.60; zinc, 0.34; phosphorus, 0.28. A chemical analysis of several wires from the steel cables gave the following composition: carbon, 0.64; manganese, 0.55; phosphorus, 0.033; sulphur, 0.033.

In Fig. 3 is shown the arrangement of the wires and strands in the four different types of cables.

Stress-strain curves for computing the modulus and locating the elastic limit were plotted on cross-section paper with a scale of 1 in. equal to 0.01 in. actual elongation in 50 in. The vertical scale was made so as to give the curve a slope of about 45 deg. with the horizontal. This large-scale plotting showed the readings of the extensometer to be very consistent, indicating that the cable was stretching uniformly and also twisting uniformly.

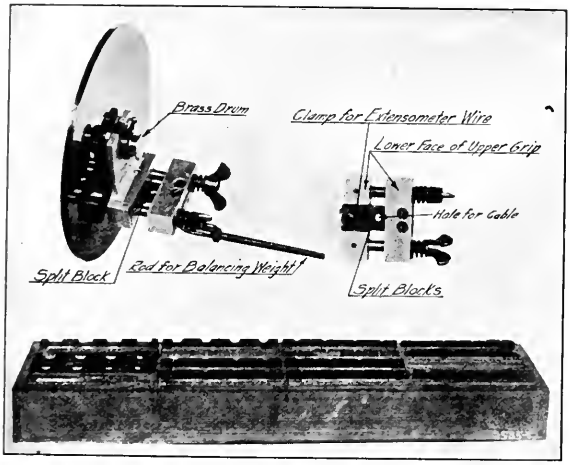

Fig. 2 Extensometer Clamp

The values for elastic limit were obtained by selecting the highest point on the straight-line section of the stress-strain curves. Strictly speaking, this is not the elastic limit but the proportional limit. (American Society for Testing Materials.)

However, as the majority of practical designing engineers use the term "elastic limit" to designate what is actually the proportional limit, we have also used it in that sense in order to avoid confusion.

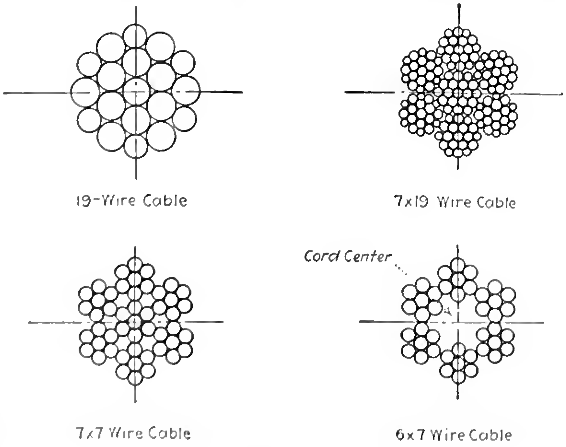

Fig. 3 Types of Cable Construction

There is considerable variation between the modulus of different-sized specimens of the same type. In order to show the comparative modulus values for the different types of cable, Table 2 was prepared, selecting the same size of cable from each type as nearly as it was possible to obtain.

There is in several cases quite a difference between the first-run modulus obtained on different specimens of the same cable. The largest of these differences is in these $^1/_8$-in. 7 by 19 cable, specimens 13 and 14, which show a difference of about 3,200,000; and the 6 by 7 cable, specimens 16 and 40, which show a difference of 2,760,000.

The highest modulus obtained on any cable is 27,793,100. This value was obtained after loading below the elastic limit. It should be remarked here that this value is more than twice as large as the value 12,000,000 which is commonly quoted for wire rope.

The largest increase in modulus is found in the $^1/_8$-in. 7 by 19 cable, which shows an increase of 6,600,000 after loading above the yield point. It is noticeable that this maximum increase occurs on the smallest-sized cable. The phosphor-bronze cable shows the smallest increase in modulus of any of the other cables, even though it is of the same type of construction (7 by 19) as the one which showed the greatest increase.

TABLE 1 TYPES AND SIZES OF CABLES TESTED

Type	Material of Wires	Protective Coating on Wires	Diameter of Cable
19 wire	Steel	Tinned	$^1/_{32}$*, $^1/_{16}$, $^7/_{64}$, $^1/_8$, $^5/_{32}$, $^7/_{32}$
7 by 7	Steel	Zinc-plated	$^1/_{16}$, $^3/_{32}$, $^5/_{32}$
7 by 7	Steel	Tinned	$^3/_{32}$
6 by 7	Steel	Zinc-plated	$^9/_{64}$
7 by 19	Steel	Tinned	$^1/_8$, $^5/_{32}$, $^7/_{32}$, $^9/_{32}$, $^{11}/_{32}$
7 by 19	Phosphor-bronze	None	$^7/_{32}$

* This cable has only 7 wires because of its small size.

TABLE 2 COMPARATIVE MODULUS VALUES FOR DIFFERENT TYPES OF CABLE

Type	Size	Average 1st Run Modulus	Average Modulus after Loading above Yield Point
19 wire	$^5/_{32}$	24, 870, 000	25, 687, 000
7 by 7	$^5/_{32}$	19, 505, 000	22, 985, 000
6 by 7	$^9/_{64}$	17, 989, 000	20, 660, 000
7 by 19	$^5/_{32}$	15, 605, 000	20, 112, 000
7 by 19[1]	$^7/_{32}$	11, 307, 000	11, 953, 000

[1] Phosphor-bronze.

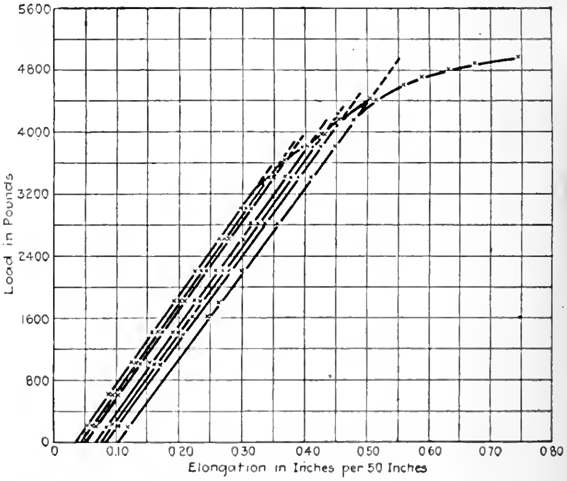

Fig. 4 Rise in Elastic Limit of $^3/_{16}$-in. 19-Wire Non-flexible Steel-wire Cable

While it is true that the modulus is raised a greater amount by loading above the yield point than below the elastic limit, it is to be remembered that a very large part of this increase is due to the loading below the elastic limit. It is evident, then, that the net effect of loading above the yield point is small.

The final object of this investigation was to determine whether it is possible to raise the elastic limit by loading a little beyond this point. The results of one set of runs made to show this are given in Fig. 4. These curves indicate definitely that the elastic limit can be considerably increased.

The amount of increase obtained on the cables tested is as given in Table 3, page 111.

(Continued on page 111)

Air Lines and Some of Their Problems

By R. B. C. NOORDUYN,[1] NEW YORK, N. Y.

To those who are interested in the early and successful development of commercial air lines in this country, this paper will give an index of the problems to be solved, both from the point of view of development of the machine itself, as well as of such important accessory factors as proper landing facilities, ground organizations, legislation, and insurance.

The author gives a detailed account of the progress of commercial aviation in Europe, tracing the development from the time of the post-war experimental work with military machines and fields, to the present successful operation with proper machines and schedules and with Government subsidies.

His ideas are authoritative, and hence valuable, and his presentation of the problems of air lines should do much toward helping to secure the establishment of air travel in this country as a factor of every-day life.

THE air lines in operation in Europe since 1919 have proved a great attraction for Americans who have formed, in fact, a surprisingly large percentage of the passengers carried. The favorable impression which they invariably bring home of the new method of travel encourages the belief that once air lines are running in this country and can promise to equal the performance of those with which the traveler has become familiar abroad, public support will be forthcoming to a greater degree than has been generally anticipated.

In the United States last year, the mileage covered by commercial or privately owned airplanes was estimated by the Manufacturers' Aircraft Association, from reports received from operators all over the country, to be not less than six million miles, in the course of which some 225,000 passengers were carried. The Frenchman, who is accustomed to using a time-table for the next plane for London or Amsterdam, and buying his ticket at the nearest travel bureau looks at these figures and thinks that the air lines in this country must be doing a good business. If this large mileage were actually covered in the operation of scheduled services over fixed routes, instead of in unorganized short flights, we could indeed consider air-travel to be an established factor in every-day life.

As a precursor of regular services the present volume of flying must not be underrated. Its educative value is very great as the passengers carried on short flights now will be the patrons of the air lines of the future. Further, personnel, pilots, and mechanics are being trained, and ground organization, landing fields and service stations are being developed all over the country, although slowly and on a modest scale.

What, then, are the difficulties which have so far stood in the way of rapid development of regular inter-city air lines in this country?

Briefly, the airplane finds itself today in that stage through which many new inventions have passed, and in which the article itself has reached a more advanced state of development than the facilities and accessories necessary for its completely effective use.

The modern commerical airplane has all the qualities requisite to passenger vehicles generally, whether land, sea, or air going, with the addition, naturally, of a few of its own. As for comfort, passengers are seated in chairs similar to those in a Pullman car, in cabins easily entered through full sized doors a step or two from the ground, protected from wind, cold and engine smells. They view the scenery through large windows. The motions of an airplane are far more gentle than those of any other vehicle, while sense of speed and vertigo are entirely absent in straightforward flying and there is no dust or dirt.

Safety and reliability under organized operating conditions are now such as to justify anyone in entrusting life and property to the air; according to the latest time-tables the regular passenger and freight lines in Europe are covering 22,000 miles per day. Table 1, a summary of British Air Ministry weekly reports on the traffic between London and the Continent, shows some interesting figures. On the three routes operated, 3088 flights were started during the first 10 months of 1921, of which $91\frac{1}{2}$ per cent were carried out in good order, which represents a distance of 700,000 miles flown and at least 6200 starts and landings made without one single passenger being hurt seriously. These figures are the more remarkable when taken into consideration with the very unfavorable weather conditions for which the region of the English Channel is notorious.

The United States Air Mail Service, which is operated over a series of route sections somewhat shorter in average length than the European lines, completed 95 per cent of the 6690 flights attempted during the first 9 months of 1921, in the course of which 1,332,000 miles were flown with mail. On the Cleveland-Chicago section the twenty-fifth successive week of 100 per cent performance was recently reported. However, it must be remembered that the Mail Service is supplied with a far greater number of airplanes and engines in proportion to the length of its routes than any private company striving to operate at a profit could afford, and also that, when carrying mail only, flights often can be successfully carried out under conditions which would be incompatible with the safety of passengers. The figures given do not, therefore, provide a satisfactory basis on which to judge the relative merits of equipment and personnel between the U. S. Air Mail and the European passenger lines, as far as regularity of performance is concerned.

TABLE 1 OFFICIAL STATISTICS ON THE AIR LINES BETWEEN LONDON AND THE CONTINENT

From January 1, 1921 to October 30, 1921. Approximate total mileage flown 700,000 miles. Not a single passenger killed or injured.

ROUTE	Distance in Miles	Number of Journeys	Passengers Carried	Journeys Carrying Mail	Journeys Carrying Freight	Journeys Completed to Schedule	Percentage of Journeys Completed	Type of Machines

[1] Service suspended owing to fire at Brussels aerodrome Sept. 28, 1921.
[2] Commenced operations April 14, 1921.

Finally, in judging the present status of the airplane as a means of transportation, the all-important question of operating cost must be considered. The first air lines started operations hopefully, on the assumption that their small first outlay, on the purchase of converted war planes at a fraction of the manufacturing cost, and the supposed imperative demand of modern business for speed above all things, would insure at least a paying business from the beginning. How sadly they were disappointed is clearly shown both by the history of the companies concerned and the rapid, if not yet quite complete, disappearance of these machines from the chief airways of Europe.

Large numbers of 3-seater machines, converted fast day bombers, were in use during the first year or two after the war, which showed a dead financial loss on every trip, even when loaded to full capacity which was by no means always the case. Large twin-engine bombers, capable of carrying about 10 passengers, solemnly ploughed their way daily between London and Paris and London and Brussels, more often than not less than half loaded, and at a prohibitive cost in gasoline and oil for their big engines. The fares charged had to be very high and the vicious circle was complete.

The technical results—mechanical reliability and ability of the pilots to make their way in bad weather in spite of the rather primitive meteorological and other ground services available at that time—were surprisingly good, but the financial results were disastrous and produced a great deal of adverse opinion.

---

[1] Netherlands Aircraft Mfg. Co., New York, N. Y., Fokker representatives in America. A.M.I.Ae.E.

Paper presented at the Annual Meeting, New York, December, 1921, of The American Society of Mechanical Engineers. All papers are subject to revision.

It was not until the French Government heavily subsidized the French lines and enabled them to make a cut of 40 per cent in their rates, that traffic began to increase; with this assistance, the old war types, uneconomical as they are, took on a further lease of life in France and are still widely used in that country. To enable the British companies to compete, the British Government assisted them by financing the acquisition of modern commercial planes on a repayment basis, and guaranteed a profit. The effect of these steps on the traffic itself is well shown by Table 1. In the meantime the principal constructors had given their serious attention to the problem of increasing the carrying capacity and reducing the running costs and the new machines showed a remarkable improvement in this respect.

It is interesting to note the successive steps toward this realization of the chief commercial requirement, the carriage of greater loads at less expense. Just before the dissolution of the pioneer concern—The Aircraft Travel & Transport Co.—a desperate effort was made to improve matters in this respect. Operations were placed in the hands of traffic experts pure and simple, who, quite justifiably, at once tried to increase the service obtained per week from the equipment in hand, such as it was. Undoubtedly this effort provided a vast amount of data on constructional details such as accessibility of engine installations, ease of repair and all matters which would become especially prominent as more work in a given time was demanded of each airplane as a unit. The results only emphasized more respects in which the coming commercial designs had to show improvement over the converted war types, aside from carrying capacity and load space.

The requirements having thus become clearly established, the designers set out to fulfill them. After the 360-hp. DH16, really a converted DH4, carrying four passengers in very cramped quarters, and subsequently the BAT, FK26, which carries a slightly greater load with the same horsepower in a good-sized cabin, this progress in design was very marked in the 450-hp. DH18, carrying eight passengers which was very soon followed by the Fokker monoplane with five passengers for 185 hp. With these the useful load carried per horsepower had advanced from 4 lb. to 8 lb., or an improvement in commercial performance of 100 per cent. The internally braced monoplane, in which the airplane finds itself practically reduced to its essential parts, lifting surface, body, chassis and controlling organs comprising the entire structure of the machine, has opened up fields of study in the matter of wing design which promise still further progress in this direction. Within recent months several new designs on this principle have appeared and are in successful operation, which again show an advance in carrying capacity. Notable among these are the new DH29 and the new Fokker F4, which carry from ten to twelve passengers and considerable baggage with engines of 400–450 hp., the useful load carried per hp. thus having now advanced to 9 lb. Roughly, this means that such airplanes can carry a load of more than one ton in passengers and freight a distance of 600 miles in 6 hours at a fuel cost of $48, or $^3/_4$ of a cent per passenger mile.

The few figures given go to show that the airplane, even in its present state of development, is by no means a hopelessly costly means of transportation, provided that facilities for its exploitation are developed to a sufficient extent so as not to entail the addition of entirely disproportionate overhead charges to the actual running cost, charges of a character with which no other form of transportation has to contend or is able to bear. In the following paragraphs a few of the factors governing these charges are discussed.

The Selection of Routes

What has been said gives an indication of the airplane's present capacities and also of the trend of development in the near future. The next question is, obviously, where can it be put into regular service with a reasonable expectation that that service will become truly a public utility and receive sufficient support to thrive as a commercial venture?

It may be argued that eventually air traffic will have its place in the scheme of things alongside the older and slower means of transit, wherever traffic of any kind—or at least long distance traffic—exists. However, it is obvious that in choosing the routes to be operated during the introductory period very great care will have to be taken to select those on which the air lines are likely to justify their existence within a reasonably short time. Such routes may be fairly clearly divided into two categories. First, there is the route between commercially or politically important points, of which the development has been so rapid that transportation facilities have been unable to develop proportionately. The new world is full of such opportunities for the airplane, the only vehicle which is practically independent of geographical obstacles and does not entail the laying down of a permanent right of way.

Second, there are routes on which terrestrial tranportation facilities are very highly developed and the volume of traffic very great, but where at the same time communication is retarded by natural obstacles which do not affect the airplane to any considerable extent. Chief among these are mountains and intervening stretches of water entailing either transshipment or circuitous routes.

In either case, the decision that the establishment of air communications is a justifiable venture can only be made after careful study of existing transportation facilities and local conditions. The full support of the foremost industrial and business interests in and around the terminal cities must be obtained; and extensive preliminary canvassing and propaganda work are essential with a view to enlisting coöperation by the community in the establishment of air terminals and other facilities analogous to those provided for shipping as well as to insure patronage once the air line is in operation.

The public has to be taught how to use the airways; even with air lines in full operation a great deal of publicity work and effective advertising will be necessary to show the business man just how to combine the new transport facilities with the older ones in order to take full advantage of the airplane's speed. This is especially the case as long as night flying is not practicable, or rather, not organized and regularly carried out, thereby necessitating the coördination of train- and air-service schedules for long-distance transportation.

Especially in the early days, the European lines suffered from lack of appreciation of the value of this educative publicity, a fact which contributed immeasurably to their difficulties in obtaining satisfactory loads. Both by this example and the far greater development of the science of advertising in this country, the coming American lines should have a considerable advantage over the European pioneers in this respect.

In the establishment of the first lines many similarities to the early days of railroading will be found, but many of the trials of the latter, both technical and financial, may be avoided. Compared with the railroad, the capital outlay involved in the air line is fractional; the non-requirement of permanent tracks involving the possession of immense tracts of land, will always be among the chief advantages the airplane possesses over any other means of overland transportation.

Ground Organization

Nevertheless, real estate values effect the increasing commerical use of the airplane to a considerable extent. There is probably no other single factor which has been so effective in retarding the general use of aircraft in this country as the lack of landing fields. Such privately owned flying fields as there are, are in only too many cases small, with obstructed surroundings and inadequate for highly loaded commerical craft. The military fields, which in Europe form the backbone of the airways, are few in the U. S., even including those abandoned after the war; also they are generally located just where the ground happened to be naturally suited for training in flying, far removed from large cities. In Europe important centers were liable to attack by enemy airplanes and defensive squadrons had to be stationed close at hand. Even in the case of the European capitals, however, the air ports now established on these old military fields are in most cases much further away from the cities than is desirable for commercial flying. If two hours have to be spent in transportation to and from the airports, in order to make a $2^1/_2$-hour journey by airplane, the saving of time over the railroad, at least where the latter provides an efficient and direct service, is practically lost, and the air line is not likely to flourish.

This problem is admittedly in most cases difficult of solution. The nearer the center of a town, the more valuable land becomes;

however well financed, the cost of such land suitable as an air port is not one which a new transportation company, which has yet to develop a popular demand for its service, can be reasonably expected to bear. The analogy with docks and harbors, of which the initial cost is borne by the city treasury, is obvious, but it is also demanding much from a city's foresight and enterprise to expect it to lock up a great amount of capital in reserving large tracts of valuable land near the business center, of which—especially at first—very scant use will seem to be made. As traffic develops, increased landing fees, hangar rents and other dues will improve the immediate financial aspect, until the time, which may not be so far distant as to be visionary, that long distance airliners will land on platforms covering the stations, yards and part of the tracks of the local railroad lines or even several city blocks.

To a layman, it would seem that in this question of reserving centrally located tracts of land as airports for a number of years there may be much to interest real estate manipulators.

The arrangement of emergency landing fields at short distances apart, along the routes, should not present any difficulties. Their preparation may involve the removal of a few trees and other obstructions and the erection of suitable markings as a guide for pilots when in difficulties due to weather or mechanical trouble, but otherwise they can retain their normal functions if meadow land is selected.

A most important part of the ground organization is the provision of a specialized and adequate meteorological service. A considerable development of the existing Government meteorological institutions or weather bureaus will be necessary, since the information obtainable at the present time is of very little use for air navigation. In Europe, government weather experts and radio services are installed on the principal airports, and reports are obtainable hourly. In England it was so well recognized that air navigation was bound to develop the knowledge and organization of meteorological work, that shortly after the war the existing government meteorological office was placed completely under the control of the Air Ministry.

Such further auxiliary services as directional radio and beaconing the airways by night, will eventually all have to be recognized as a public service and undertaken by the Government; the pooling of facilities by different railroad companies may be a matter of private arrangement and not the concern of the public, but the following of organized airways and the picking up of radio signals will automatically become a public right.

Legislation and Insurance

As is the case with any form of transportation, the perfection of organization, mechanical reliability and standing of personnel ought to be reflected clearly in the terms on which equipment passengers and freight are accepted for insurance by the large companies, and it may be fairly regarded as illustrative of the condition of commercial flying in this country that the state of affairs in aircraft insurance is far from satisfactory.

At present the position of an insurance company called upon to quote on aircraft risks is not enviable. The entire absence of any legislation to place responsibility for even the most elementary consideration of public safety, by controlling the efficiency of aircraft and ground organization, combined with the scarcity of such ground organization in the form of landing fields and auxiliary services, would induce any company to keep clear of taking aviation risks for the present, were it not for the necessity of obtaining experience and statistics as a basis for the business which the development of air transportation on a large scale will eventually offer. As it is, the present state of the aircraft insurance market may justifiably be described as chaotic. Again, risks have been accepted which should never even have been considered, and the consequent losses duly paid, while on the other hand premiums have been quoted which must have been based on a considerable "factor of ignorance," being, apparently, out of all proportion to results already been obtained elsewhere under conditions sufficiently similar to those involved in the proposal.

The institution of a system of registration and inspection of aircraft and pilots by the Insurance Underwriters Laboratories is a great step in the right direction. To make the system fully effective, it is to be hoped that legal confirmation of the powers of that body will soon follow. The assignment of such technical duties to a semi-public institution, instead of to a Government department—which principle has a strong precedent in the case of shipping in Lloyds—is in many respects preferable. The rapid development both of the airplane and its application, may necessitate frequent and urgent changes in existing regulations, with which necessity it will be difficult to keep pace if technical details are incorporated in Federal laws.

The effect which proper legislation will have on the financial stabilization of air transportation in general, both through the creation of reasonable insurance facilities, and through the definition of the legal status of the airplane and that of its operators, is well illustrated in the case of passenger liability. When legal liability for the safety of passengers and third parties is determined, insurance against these risks will become possible. At the present time the risk cannot be determined. Possibly claims on one accident are limited to the value of the machine to which it hapened, as under Admiralty Law (which presumably already applies to seaplanes); possibly they are not. The operators of aircraft can only print a strong cover against liability on their tickets, or perhaps incorporate each plane as a separate company, and find comfort in the safety statistics. It is to be noted that the latter have already led the English insurance companies to strike the clause refusing flying risks from the ordinary life policies.

With the development of the air lines, the insurance rates will undoubtedly always serve as an excellent index on the effectiveness of whatever legislation or regulation there may be and of the soundness of air transportation as a public service and a business.

A Few General Conclusions

In reviewing the possibilities of an early and successful development of air lines in this country it is imperative that the European pioneering in this sort of traffic be closely watched and that the greatest possible use be made of the experience and statistics it has provided. Except as regards purely technical matters, however, these should be applied to American projects and prospects with great circumspection and the difference in political and economic conditions be kept clearly in view. The case of direct government subsidies is a striking one, these having been largely responsible for the development of traffic in Europe, while they are practically unthinkable in this country. What is wanted from the Government here is what may justifiably be looked upon as its natural obligations, that is, the provision of facilities of all kinds, as outlined above. That direct financial assistance ever fosters true progress and new developments no one believes. Human nature being as it is, the tendency is inevitable to regard official aid as manna from Heaven and let things take care of themselves; not to speak of the countless opportunities for favoritism, intrigue and worse, that it entails. Abroad, conditions are different in that respect. It should not be forgotten that most European trunklines are international in character and that national pride and political expediency are potent factors in matters of this kind. Also that the various governments have a much greater interest in the maintenance of a commercial air-fleet as well as a ground organization that can be requisitioned at short notice in case of need, than will ever be the case in this country.

Apart from their questionable desirability on the grounds touched upon above, direct subsidies should not be *necessary*. The variety of geographical and economic situations which the United States offers within its own boundaries will provide plenty of scope for financially successful commercial flying operations, if properly taken in hand with proper equipment. The moment that air transportation shows its inherent advantages to the business men of America it will be used on a scale which will leave European traffic figures far behind from the very start. The history of the automobile is a good example.

The amount of traffic, both in passengers and express matter from which the air lines will be able to draw their share, is great. The "magnificent distances" to which President Harding alluded in his recent message on this subject automatically insure the saving in time that makes air travel pay.

But the first steps are always the hardest and official support in some practical form for operators and builders of commercial

The Strength of Airplane Rib Forms

Description of An Investigation to Determine the Strength of Plywood Webs, with Lightening Holes Arranged as in Airplane Ribs

By D. T. BROWN,[1] PHILADELPHIA, PA. and R. J. DIEFENBACH,[2] BUFFALO, N. Y.

As illustrating the problem of the strength of materials entering into airplane construction and the degree of research necessary for their proper solution, the following report of an investigation carried out at the United States Forest Products Laboratory will be of interest. In the design of airplane ribs the prime requisite is to obtain the maximum strength with minimum weight of rib. Two factors enter into the problem: the form or design of the rib and the method of its construction in relation to the grain of the material. It will be seen that the investigation reported was conducted in a very complete manner and that conclusions of great value in the design of this essential part of the airplane are brought out.

THE great difference in the strength properties of wood along and across the grain has long been recognized as one of the features restricting its use in structures. Tests made by the U. S. Forest Products Laboratory show that the approximate ratios of the strength properties in these two directions are: The modulus of elasticity across the grain is one-fifteenth of that along the grain; the tensile strength across the grain is one-twentieth of that along the grain. These ratios do not apply exactly to any individual species, since different species vary largely in this respect.

A very material reduction in the differences along and across the grain is obtained in ply-wood construction by gluing together successive sheets of veneer with the directions of the grain at right angles, and varying the proportion of grain and number of plies in the two directions.

In the design of airplane ribs the prime requisite is to obtain the maximum strength with minimum weight of rib. This series of tests has been made to find the strongest form of rib, taking into account the two factors above mentioned by placing the grain of the veneer 45 deg. to the vertical. In modern practice the face grains are vertical and the core horizontal. Most of these tests, however, were made with the face grains parallel and at 45 deg. to the vertical with one core at 90 deg. to the face grain.

DESCRIPTION OF THE MATERIALS USED

Birch veneer $^{1}/_{28}$ in. thick was used. In order to obtain a fair comparison in the tests, all of the veneer used in making up the ply-wood was cut from one log. The veneer used consisted entirely of heart wood, the log being sufficiently large to eliminate the need of using any sap wood. No pieces containing knots or checks were used. The veneer had been in store for some time and was well seasoned.

The veneer was glued together into three-ply ply-wood by the Theodore Schwamb Company, which specializes in such work. The ply-wood was cut into specimens $4^{1}/_{2}$ in. wide by 18 in. long. As already noted, the face grains were parallel and in most of the tests at 45 deg. to the vertical, and the core was placed at 90 deg. to the face grains. One of the chief objects of these experiments was to determine the effect of making the web of a rib from plywood with the grain at 45 deg. to the chord, so that the grain runs parallel to the directions of the principal stresses at the neutral axis of the web.

The ply-wood now used in practice in airplane ribs is made up with the face grains parallel and usually vertical and the core horizontal. This method has proved generally stronger than if the reverse disposition is used, that is with the face grains parallel and horizontal and the core vertical.

In order to prove the superiority of the method suggested in this paper some specimens were made according to modern practice and tested under like conditions.

THE METHODS OF TESTING EMPLOYED

In all cases the specimens were tested as cantilevers at a 15 in. arm. Spruce flanges $^{1}/_{4}$-in. square were glued on the sides of the specimens to prevent lateral collapse as a whole. In order to insure a definite length of cantilever arm and also for holding purposes, a hardwood block, $^{1}/_{4}$-in. by $3^{1}/_{2}$-in. square was glued on each side at one end of the specimen. The specimens were held in a wide-jawed vise; knurled jaws were used to avoid slippage. The load was applied by a smooth-acting screw jack, and the force was measured by placing the screw jack on a small platform scale which could be read accurately to one pound. Upon the head of the screw jack, a round steel bar was placed. This insured a concentrated load at the end of the cantilever.

THE RESULTS OBTAINED

In the rectangular type of lightening hole with constant web thickness and variable fillet radius, it was found that below $^{3}/_{4}$ in. radius the fillet was of but little use.

The specimens for the tests made in the next group, were made with variable radius of fillet using lattice construction. A maximum of 283 lb. was reached in this group. Since 181 lb. was the maximum force applied at the end of a 15-in. cantilever with vertical grain and rectangular holes, and since it has generally been found that lattice design with triangular holes is little, if any, stronger than that involving amply filleted rectangular holes, if vertical or horizontal face grain is used in both cases[1] the advantage of diagonal-grain design for the lattice form appears to be clear. The comparison between the best case with diagonal grain and lattice design and the best arrangement of rectangular lightening holes with vertical grain expressed in percentage change from the second to the first is as follows:

Radius of fillet, in.	Increase or decrease of area not cut out (change of web weight, per cent)	Increase or decrease of force applied to produce failure, per cent
$^{1}/_{4}$	−29	+12
$^{1}/_{2}$	−2	+29
$^{3}/_{4}$	+2	+56

The advantage of the lattice construction is obvious. Inspection of Table 1, where the ratio of strength to area of web is given, indicates that that ratio is little affected by radius of fillet, the smaller radii having a slight advantage.

TABLE 1 RATIO OF STRENGTH TO AREA OF WEB

Type of Construction	Variable	Width of Vertical or Diagonal Web Members, in.	Radius of Fillet, in.	Character of Failure	Distance between Center of Cross	Per cent of total Area Cut Out	Per cent of Area Remaining	Force Applied at end of 15-in. Cantilever, lb.	Force ÷ Per cent of Area Remaining
Rectangular lightening holes	Radius of fillet	$^{1}/_{2}$	0	Shear	....	76.1	23.9	50	2.09
		$^{1}/_{2}$	$^{3}/_{4}$	Shear	....	73.1	26.9	55	2.04
		$^{1}/_{2}$	1	Shear	....	70.7	29.3	64	2.18
		$^{1}/_{2}$	$1^{1}/_{4}$	Shear	....	67.7	32.3	97	3.00
		$^{1}/_{2}$	$1^{1}/_{2}$	Shear	....	63.9	36.1	134	3.71
Lattice	Radius of fillet	$^{5}/_{16}$	$^{1}/_{4}$	Compression	....	74.6	25.4	202	7.95
		$^{5}/_{16}$	$^{1}/_{2}$	Compression	....	70.3	29.7	233	7.85
		$^{5}/_{16}$	$^{3}/_{4}$	Compression	....	63.3	36.7	283	7.71
Lattice	Thickness of web	$^{5}/_{16}$	$^{1}/_{4}$	Compression	....	74.6	25.4	202	7.95
		$^{3}/_{8}$	$^{1}/_{4}$	Compression	....	73.0	27.0	238	8.82
		$^{7}/_{16}$	$^{1}/_{4}$	Compression	....	71.5	28.5	256	8.98
		$^{1}/_{2}$	$^{1}/_{4}$	Tension	....	69.9	30.1	278	9.24
Crossed lattice	Distance between center of cross	$^{1}/_{4}$	$^{1}/_{4}$	Compression	7 in.	70.9	29.1	201	6.90
		$^{1}/_{4}$	$^{1}/_{4}$	Compression	6 in.	69.3	30.7	230	7.49
		$^{1}/_{4}$	$^{1}/_{4}$	Compression	5 in.	67.2	32.8	280	8.54
		$^{1}/_{4}$	$^{1}/_{4}$	Flange	4.5 in.	65.7	34.3	295	8.60

The ratio of strength to weight is steadily improved by increasing the width of the diagonals, although the improvement is slow for widths of $^{3}/_{8}$ in. or more.

A crossed-lattice arrangement with a spacing between the crosses

of 1.5 times the depth of the lightening hole appears to be approximately equal to the best straight-lattice arrangement. It is difficult to make a satisfactory direct comparison, as the required depth of the horizontal portions of the web, above and below the lightening holes, varies with the distance between lattice members. With due allowance for this fact, a very close spacing of the crosses seems to be best.

With forces in excess of 300 lb. the flange fails by shearing. In the crossed-lattice construction true shear failure of the diagonals never occurred. The compression members are supported by the tension members in such a way as to decrease the free length of the column under compression.

In connection with this crossed-lattice group some specimens were tested with the compression member left out in every other cross. This arrangement is palpably inferior to the straight-lattice or continuous crossed-lattice. It was found that the crossed-lattice type did not stand up so well relatively with web thickness of $^{3}/_{16}$ in.

A continuous cross lattice spaced at 3 in. with vertical grain, carried 214 lb. Even this design is far better than that with rectangular holes.

Finally a test was made with no area cut out and it failed by buckling of the flange at 325 lb.

It was observed in the tests made that there was but little deflection with both the straight lattice and cross-lattice type. The deflection with the rectangular type was much more pronounced.

PROGRESS IN FLYING DISCUSSED

PRACTICALLY all of the discussion at the session was on the commercial aspects of aviation. Mr. Joseph A. Steinmetz, chairman of the Executive Committee of the Aeronautic Division, discussed the present status of aerial development, describing the progress in Europe from first hand observation this summer, and the progress in this country, especially in the South, where commercial lines are about to be inaugurated. In the construction and development of aviation throughout the world, he saw tremendous possibilities for the art within the next few years.

Prof. E. P. Warner, Massachusetts Institute of Technology, who presided at the session considered that our fundamental purpose is the development of commercial flying, which has ceased to be a problem of design and construction, and has become one of publicity.

Lieutenant E. E. Aldrin, secretary of the Division in the discussion of Mr. Noorduyn's paper, detailed his experiences on the London to Paris Air-Line this summer. He said there was no question of the advantage of commercial flying, if only from the point of saving time.

Commercial flying in Europe is now developed to the point that the passenger uses a time-table just as he does for a railroad train.

Then again, the comforts of the air journeys are a favorable consideration.

Mr. Foster Russell[1] asked a number of questions regarding the cost of carrying mail and Major Lent answered him, pointing out also that there was much greater promise of commercial success in carrying goods, such as mail, than in the transportation of passengers. A study had been made of the profits to be derived. The commercial companies acknowledged that they were after express business and other high class matter, and would be glad to avoid the risk of carrying passengers.

Mr. Noorduyn answered a question of Mr. Russell's that the Government would gladly turn over the carriage of mail to private transportation companies provided that they could show satisfactory prospects of rendering good service, but that the Congressional appropriations would not allow the payment of a higher rate for air-line transportation than by any other means.

There was considerable discussion of the possibilities of aircraft landing fields, and Mr. Steinmetz related his experience in getting such fields. He said the way to do it was to get a City Plan Conference to set aside a big fair ground, or a county exposition field, and then get an engineer to go over the layout with them and put in an aircraft landing field. Later on they could be shown their great wisdom and foresight in providing for an air port for world traffic.

Mr. Russell, thought the main problem of commercial flying was the provision of a machine which could be made and sold very much like a Ford automobile is sold, something that could be sold to farmers. He also gave his experiences with landing fields, reciting some of the cases encountered in trying to get such fields. He thought the best thing to do was to get airplanes in the air and the landing fields would come.

Several of the speakers present discussed the feature of safety in commercial flying, and there was a general agreement that great publicity should be given to the relatively small amount of risk, added to the extreme pleasure of this form of transportation.

Among those who took part in the discussion was Mr. Charles Manly, past president of the Society of Automotive Engineers, and a well-known figure in the practice of aviation. Mr. Manly outlined in great detail the things that would have to be done to make commercial flying popular with the public, and to make possible the development of commercial aviation companies on a profitable basis, without which there could be no commercial flying. The only other thing to be met was that a machine should be provided which could be bought for a reasonable price.

ELASTIC PROPERTIES OF SMALL-SIZE WIRE CABLE

(Continued from page 106)

TABLE 3 AMOUNT OF INCREASE IN ELASTIC LIMIT OBTAINED ON THE CABLES TESTED

Type	Size	Increase in Elastic Limit, Lb.	Per Cent Increase over Original Elastic Limit
19	$^{7}/_{32}$	2000	62
	$^{3}/_{16}$	1000	33
7 by 7	$^{3}/_{32}$	250	63
6 by 7	$^{9}/_{64}$	210	30
7 by 19	$^{1}/_{8}$	400	36
	$^{11}/_{32}$	2000	33

CONCLUSIONS

The modulus of elasticity of small-size wire aircraft cable varies from 15,000,000 to 28,000,000, depending upon the size and types of the cable. The 19-wire cable has undoubtedly the highest modulus and the 7 by 19 cable probably the lowest. The maximum difference between moduli of specimens of the same size and type of cable may be as high as 3,000,000.

The modulus of elasticity may be raised by loading the cable below the elastic limit. The greatest increase is obtained on the 7 by 19 type and may amount to 6,500,000.

Resting the cable did not seem to have any definite effect on the modulus.

The elastic limit may be raised by loading the cable a little beyond this point. The maximum increase obtained amounted to 63 per cent of the original elastic limit.

The complete paper contains curves of all the runs in the different sizes, also complete logs of the tests.

AIR LINES AND SOME OF THEIR PROBLEMS

(Continued from page 109)

aircraft would do much to ease the situation. Contracts for the carriage of mail at rates, commensurate with the increased rapidity of delivery, could be given to reputable air transport concerns whose facilities for carrying out their engagements would bear investigation. Congress can make this possible as it did when mail coach and couriers were replaced by the railroad.

Another valuable form of subsidy would be the development of all purely war-types of machines in the shops of commercial builders and a system of awarding to designing firms paying production contracts for their own original products. Thereby would the aeronautical industry regain a good deal of the confidence which apparently it has lost. And the blending of the newest ideas in aeronautical warfare or defense with the most modern developments in efficiency and reliability would go a long way, in the writer's opinion, toward the reëstablishment in this country of supremacy in the air.

A Session on Fuel Economy

Discussion of Four Papers at A.S.M.E. Annual Meeting Brings Out Many Experiences in Economic Boiler and Furnace Operation, Leading to Great Fuel Savings

THE Fuel Waste Session of the Annual Meeting of The American Society of Mechanical Engineers, held Thursday morning, December 8, 1921, attracted a large audience and a voluminous discussion on account of the popular interest in the subject. Prof. L. P. Breckenridge, Chairman of the Fuels Division, presided at the meeting. The papers presented were, Boiler Plant Efficiency, by Victor J. Azbe: Boiler and Furnace Economy, by D. S. Jacobus; Fuel Saving in Relation to Capital Necessary, by Joseph Harrington; and Fuel Saving in Modern Gas Producers and Industrial Furnaces, by W. B. Chapman. All these papers have already been published in MECHANICAL ENGINEERING.

ALL CONCEDE MR. AZBE'S STATEMENTS SOUND

J. M. Spitzglass[1] quoted the following paragraph which, he said, he believed to be the keynote of Mr. Azbe's paper:

> Nowhere is there such an opportunity for good return on the investment as in the boiler house, where a few dollars properly applied can perform wonders. But there are also properly designed plants that are wasteful, due to human inefficiency, and to such beliefs as that stokers are a failure, high CO_2 harmful, economizers a poor investment, superheated steam impractical, etc. It is the man who designs or operates who is at fault, rather than the equipment. The fireman is more important than the stoker and a good fireman will obtain good results from a poor stoker. But since good firemen are scarce, it is preferable to purchase equipment which is as nearly foolproof as possible.

Wm. S. Aldrich[2] wrote suggesting that in grading combustion performance, a percentage scale with maximum possible CO_2 as 100 per cent be used.

John Clinton Parker[3] spoke in commendation of the paper. He pointed out the necessity for honorable design, honorable testing and honorable operation in the engineering world.

R. Sanford Riley[4] considered the paper absolutely sound, saying that nothing sounder had been expressed before the Society than the author's ideas on differences in conditions of operation.

D. S. Jacobus[5] said he wished to add that, in getting the most out of a boiler plant, more must be considered than the efficiency of the boiler and the efficiency of the plant in general. Much of the saving to be made in boiler plants is often not in improvements in the boilers themselves, although many times such improvements can be made, but by such means as changing the system of heating feedwater, or of providing hot air, or of adjusting the heating system.

David Moffat Myers,[6] speaking in the spirit of Dr. Jacobus's remarks, told of making a saving of 15 per cent in a plant without making a single change. The firemen, conscious of his presence, had paid better attention to their jobs, with the resulting saving. In other plants he had found that merely by requiring simple records kept, economy was improved through the psychological effect on the firemen. He also spoke of the necessity of providing the firemen with an incentive for good work. Efficiency in a plant, he said, was a combination of the efficiency of the men and the efficiency of the machine.

C. H. Smoot[7] asked who was responsible for low efficiency in boiler plants—the manufacturer of the boiler, the manufacturer of the stoker, the operator, or the fireman? If it is possible to increase the efficiency of boilers from 50 to 80 per cent, as stated by the author, it seemed to him that such an organization as the Society should see to it that such savings were made.

C. Harold Berry[8] assumed that most of the statements of the author's paper referred to small plants, and not to central stations. He also pointed out that the tests reported in Table 3 of the paper were made at different ratings, which might account for some change in the efficiency. The author's statement that most stations had too many boilers did not apply to central stations.

In reply to Mr. Berry, the author pointed out that the tests referred to were run in each case at maximum capacity, showing that improved conditions resulted in increased capacity as well as increased efficiency.

DR. JACOBUS' PAPER CHARACTERIZED AS FILLED WITH WISDOM

W. F. M. Goss[9] characterized the paper as a concise statement of significant facts and a monument to the industry and scientific skill of its author. He has long had a part in the development of this field of engineering research, and much that is common knowledge today, has come through the painstaking processes which he has inspired and promoted. Underlying this paper therefore are activities incident to his fruitful life.

Edward N. Trump[10] wrote congratulating the Society on having received such an able paper as that of Dr. Jacobus, saying that it was full of the wisdom of long experience. A survey made by the Fuel Administration during the war had shown that the average efficiency of plants in the State of New York, even including the large plants operating at 80 per cent efficiency, would not be greater than 50 per cent.

While we should study the investment factor, he said, in determining whether or not to replace an inefficient plant, we must remember that the supply of coal in this country is not inexhaustible and will always increase in cost, and we owe something to posterity. We should be content to take a low rate of return on our capital, expecting other advantages which are more difficult to calculate.

He dealt with such questions as economizers, corrosion, high boiler setting, operation of boilers at high rating, furnace volume, and form of furnace as affecting the economy of operation.

Alex D. Bailey[11] wrote in reference to a statement of the author that air heaters are of special advantage where low-grade fuels are burned. While this may be true as stated, he said, it is equally true, particularly in the case of coal, that on account of the sulphur content, air heaters might operate at the greatest disadvantage.

So far as the personnel of boiler plants is concerned, probably the greatest need for education and missionary work is with managers and chief engineers who do not appreciate the importance of this part of power-plant operation.

Automatic systems for combustion control will never take the place of brains, and while these may function fairly successfully if left alone, their ultimate success would be improved by proper supervision and care.

To attract the right kind of men the conditions in the boiler room must be made attractive, and to get the best results proper equipment must be provided, so that the men with proper education and training can get the desired results.

R. Sanford Riley[12] wrote that we all agree that combustion should be completed within the furnace chamber. This requires volume and proper opportunity for mixing of the gases. He could not see, however, that efficiency is increased by the maintenance of a high temperature in the furnace between the fuel bed and the boiler. The maximum temperature due to combustion of the fuel will be obtained when there is high percentage of CO_2 without CO, or in other words, when there is a minimum of excess air accom-

panied by complete combustion. The above condition represents, of course, the highest combustion efficiency and if Dr. Jacobus means "temperature of combustion" or "fuel bed temperature" when he says "furnace temperature," he could certainly agree with his statement. The temperature within the furnace chamber, however, need not be as high as this maximum temperature of combustion.

Elsewhere in the paper Dr. Jacobus mentions the large utilization of radiant heat, and he was much impressed with the statement that B & W boilers may absorb as much as 60 per cent of the total heat by radiation. It seemed to him that this large absorption by radiation is all to the good, and the consequent lowering of furnace temperature is one reason why it is so good. No compromise is necessary in this respect, except to secure ignition. With underfeed stokers there is no need to make any compromise whatever, and the best practice seems to be to expose the maximum area of tubes to radiant heat and thus hold down the furnace temperature. This transfer of heat by radiation is the direct route "from maker to user." There is then no middleman like brickwork to take toll and cause trouble. Convection can also be considered a middleman but does not require much attention or cause any trouble.

He suggested the theory that all boiler-furnace construction should utilize radiation to the maximum, and so hold furnace temperature down to the minimum. This theory has nothing to do with the temperature of combustion in the fuel bed, which of course should be the highest possible to correspond with the minimum of excess air.

E. L. Hopping[13] presented a written discussion referring to the design of furnaces for 1500-hp. Stirling boilers, with integral economizers, at the Delaware station of the Philadelphia Electric Co. Two considerations were kept in mind;

a That the furnace be made sufficiently large to allow for efficient operation at high rating without detriment to furnace walls or stoker parts

b That in case it was found desirable, after installation of the boiler, to change to some other type of fuel burning, the cost of such a change would not be prohibitive and that conditions would be such as to produce the highest economies.

The furnace as finally designed and built has a volume of 4.8 cu. ft. per rated boiler horsepower, or about $1^1/_2$ cu. ft. per maximum developed horsepower, which is a rather high rating for stoker-fired boilers. These boilers were designed to operate at maximum capacities of about 300 per cent normal rating.

The results obtained in operation of these boilers have been very satisfactory and one condition which was not looked for has been secured. This is the practical elimination of the cinder nuisance at this plant.

Edwin B. Ricketts[14] discussed the subject of deformation temperature of furnace brickwork and methods of decreasing it by currents of steam or air or by circulating water through pipes in the brickwork. He also spoke of the lack of uniformity of size of furnace brick and methods of overcoming the difficulty.

A. A. Cary[15] pointed out the difficulty of separating the efficiency of the boiler from the combined efficiency of boiler and furnace. Notwithstanding the difficulties involved, he had found it desirable to determine individual efficiencies for boiler and furnace, and he explained his method. Dr. Jacobus' statements concerning firebrick he considered important, and he discussed carefully the problem involved in the design of the furnace, the selection of the material and the character of the clays used.

David Moffatt Myers urged the necessity of taking the matter of fuel conservation out of the hands of the individual, who will always be wasteful, and placing it with an authority powerful enough to insist upon economical utilization of this valuable natural resource, and suggested means by which this might be accomplished.

Wm. S. Aldrich offered some data covering experiences with a vertical water-tube boiler, installed originally as a waste-heat boiler and hence heated almost entirely by convection. The boiler was subsequently used with oil and with coal fuel, experiments showing that the conclusions of Dr. Jacobus were correct. This discussion spoke also of difficulties with brickwork at high temperature.

F. F. Uehling[16] wrote in amplification of Dr. Jacobus' statements regarding the presence of a small amount of CO with a high percentage of CO_2. Since the relation which the percentage of CO in the products of combustion bears to the loss up the chimney is a very interesting one, it occurred to him that a few curves showing chimney losses for different percentages of CO and CO_2 might prove not only interesting but also of value to engineers when the importance of CO content in flue gases is given their consideration. The curves were shown on the screen.

One of the most striking facts brought out in the curves is that there is not only a *loss* due to the presence of CO but *also a gain*, and the net magnitude of the CO loss is their difference. In other words, the effect of CO on chimney loss is twofold, one positive and the other negative, and the resultant actual CO loss can be determined by their algebraic summation. Furthermore the net effect of CO on the chimney loss may be plus, minus or zero, depending upon the conditions obtaining.

What actually takes place when CO is present is:

First, a loss results due to the unliberated heat in the CO itself, that is to say, the additional heat that would be available if the CO in the products of combustion had been oxidized.

Second, a gain occurs due to the fact that the more CO there is in the products of combustion for any given percentage of CO_2 the less will be the weight of the products of combustion per pound of carbon burned, and consequently the less will be the sensible heat dissipated by the flue gases as they leave the boiler.

John A. Stevens[17] spoke of the arrangements at the new central power station at Paris for preheating the combustion air to 190 deg. fahr. Another system has been devised for preheating to 170 deg. The proper temperature seems to be between 170 and 190 deg. fahr. The preheaters consist of a series of plates beyond the economizer, through which the air for combustion travels in one direction and the exhaust gases in another. The heater can be easily cleaned, both inside and outside.

Dr. Jacobus submitted additional matter after the meeting in which he said that the statements in his paper respecting the influence of the amount of boiler heating surface exposed to direct radiant heat from the fire on the efficiencies should be amplified. Where some portions of the fuel bed are much hotter than others a higher efficiency may be obtained by absorbing the maximum amount of radiant heat directly from the fuel bed rather than by mingling the gases within the furnace and afterwards passing them to the boiler. In general, however, the higher the furnace temperature the higher the efficiency. This part will be more fully covered in his closure.

Mr. Harrington's Subject a Public Affair

Walter N. Polakov[18] opened the discussion of Mr. Harrington's paper by emphasizing the fact that the conservation of our resources is in reality a public affair. Machinery, boilers and stokers, furnaces, instruments in the boiler room are of little importance unless the human element is back of them, and unless the intelligence is present to make use of what is available. The fact that daily performance does not equal test performance is due, he said, to four things: First, monotony, which is absent from test conditions; second, stimulation always present under test conditions; third, lack of coördinated brain and manual effort, as is essential in tests; and fourth, the close watch on all conditions which must be maintained during the test. It is important to increase the interest of the power-plant personnel in the use of instruments and to train them properly to observe the indications of these instruments. Whatever instruments are necessary, he said, usually pay for themselves within a short time.

T. A. Marsh[19] called attention to some changes made in the

National Research Council to Coördinate Research Throughout Country

With Assistance of All Research Agencies, Complete List of Investigations to be Kept—A.S.M.E., in First Annual Research Conference, Considers Means of Covering Mechanical Engineering Field

A MECHANICAL Engineering Advisory Committee for the Division of Engineering of the National Research Council has been formed within the organization of The American Society of Mechanical Engineers, with the Society's Standing Committee on Research as a basis. The contemplated program is described in the following article by Alfred D. Flinn, chairman of the Division of Engineering, who detailed the plan at the Annual Meeting of The American Society of Mechanical Engineers, at a Research Conference held on the morning of Thursday, December 8, 1921.

MECHANICAL ENGINEERING ADVISORY COMMITTEE FOR DIVISION OF ENGINEERING

By ALFRED D. FLINN, NEW YORK, N. Y.

MECHANICAL engineers make use, in some measure, at some time, directly or indirectly of many results of scientific research. There are, however, certain problems requiring scientific and engineering investigation which fall within the field regarded as peculiarly that of mechanical engineers. Among these, by way of example, may be mentioned problems relating to heat transfer, fatigue or progressive failure of metals, lubrication, cutting of metals, heat treatment of metals, welding, fuel economy and properties of steam.

Fields requiring research related to engineering are numerous and broad; the corresponding fields of application are occupied by the societies represented on the Division of Engineering. These societies have close contact with practicing engineers and the industries. The Division consequently came to the conclusion last Spring, that it could render best service and most wisely select and control its activities if it had the guidance of an advisory committee, or board, in each broad field of engineering. Such committees or boards are therefore being organized or have been organized in civil, mining and metallurgical, mechanical, electrical, highway, and welding fields. In some cases two or more societies having kindred interests have joined in one advisory committee.

Of course, the Division can proceed no faster in the development of these advisory committees than the societies are disposed to progress, or the committees themselves are willing to go.

Functions which the Mechanical Advisory Committee is expected to perform in its several fields are:

1 To act as clearing-house, steering committee and coördinating agency, in an advisory capacity
2 To advise the Division in selecting the most promising and feasible researches and in organizing the research committees
3 To propose researches which would be of especial interest to the A.S.M.E. and the societies associated with it in the Advisory Committee
4 To consider ways and means suggested by the Division for the conduct of the selected researches
5 To serve as the connecting link between the Division and the Society or the group represented by the Advisory Committee.

The form and degree of organization may be adjusted to the desires of the Advisory Committee. The American Bureau of Welding is an example of complete and close organization. The committee representing the A.S.M.E., at its first meeting, held December 8, 1921, preferred informal organization, leaving organizational development to be made as needs become apparent. The functions in such a field may be performed in general through sub-committees, by correspondence. It will hardly be feasible to hold meetings of the whole Advisory Committee oftener than once a year, in conjunction with the annual meetings of the Society. It may be that in the future one session of each annual meeting will be given over to a program of papers, reports and discussions on research topics under the auspices of the Research Committee.

Sub-committes may be suggested by the Division from time to time as needs arise. The interests of the Advisory Committee will suggest others. Initiative on the part of the Advisory Committee is much desired by the Division. Permit the suggestion also of an interim committee of a few members to conduct the business of the Advisory Committee between meetings of the latter.

The National Research Council has thirteen divisions. Six are devoted to general relations—Federal, Foreign, States, Educational, Research Extension, Research Information. Seven divisions are devoted to technical research, including engineering, agriculture, medicine, and the mathematical, physical and biological sciences. The Division of Engineering is made up of representatives of ten societies, including all four national engineering societies, and a number of members chosen because of their interest and their prominence in engineering.

The Division of Engineering is a switchboard, or telephone exchange, or clearing house, to bring together from one extreme the man in industry who wants to see practical results and who is loath to put money into research even then, and the man at the other end, who is called the pure scientist, and the various grades between them. One great advantage of the Research Council is that in its many committees it is able to assemble these many points of view of pure research men and the "practical" industrial men, by personal contact and by correspondence. It often happens that information or a suggestion is picked up from committee associates which is very valuable—information in the different branches of chemistry, biology, physics, geology, engineering, medicine. This feature of the work of the Research Council deserves emphasis—the bringing together of minds in many lines of scientific and industrial pursuits and the possibility of getting one man to help another, often incidentally, even though the connection of their problems at first thought seems remote.

The Division (and the Research Council as a whole) needs close contact with the various main groups of engineers in order to know how it can serve them most effectively and most acceptably. Small groups of men working in the Research Council's offices, or in committees closely connected with those offices, cannot get the various points of view which are needed except from a large group like the Advisory Committee. But if a group like this exists and can be readily reached through its chairman and its sub-committees, problems can be referred to it and sound advice can be obtained on the willingness to support a given project, or reasons for modifying or declining the proposal. At least the Division can get the suggestions of men who have been working on that line, whatever it may be, or who are prepared in their establishments to undertake to advantage the investigation selected.

At the Grosslichterfelde Laboratory, near Berlin, there is a wonderful card catalog. It is reported to have been claimed that of all the questions that came to this laboratory, eighty per cent were answered by the card index. Some one in Germany or elsewhere had worked on the subject in question and those cards showed where the information was. Be it noted that the questions sent to this laboratory were supposed to require original research work. That is the value of having information or keys to information available and concentrated at one place. In its field the Division of Engineering seeks to become useful in that way for the various branches of engineering and allied industries. Much more broadly the Research Information Service at the Washington office of the Research Council is endeavoring to build up such a collection of keys to scientific information and research personnel for the scien-

tists and engineers of the country. It will require the aid of many men who are leaders in technology and science. Engineering Societies Library is coöperating.

Interesting reports, papers or discussions presented to the Division of Engineering are offered for publication to the member society most likely to be interested. Occasionally such statements are issued as bulletins of the National Research Council.

Not a few research projects have phases which interest more than one society. Fatigue of metals has both metallurgical and mechanical aspects and concerns the civil engineer besides. Welding enters the fields of mechanical, electrical, civil and mining engineering, in addition to being a metallurgical and physical problem and interesting the welders as specialists. Heat transfer affects all branches of engineering, but especially the mechanical, the heating and ventilating, the refrigerating and the automotive societies. Highway research concerns particularly the civil, automotive and mechanical engineers. These few incompletely stated examples but indicate and emphasize the need for such a clearinghouse as the Division of Engineering.

Through the generous coöperation of the Engineering Foundation, the Division of Engineering has offices in Engineering Societies Building, 29 West 39th Street, New York, the focus of American engineering. The headquarters of the National Research Council is in Washington. Information in further detail will gladly be given in response to inquiries addressed to the office of the Division of Engineering.

PROCEEDINGS OF RESEARCH CONFERENCE

To those who heard Mr. Flinn's plea for the coöperation of The American Society of Mechanical Engineers with the National Research Council in the attempt of the latter to place on file all the information available on research, and who also heard the discussions at the conference, there came the mental reaction that an enormous amount of research along parallel lines must be going on at any time and that there is really a lack of general information as to what research is really in progress. For in the comparatively small group—about fifty—gathered at the conference, men engaged in important work learned practically for the first time of the details or work with many similarities being conducted by others sitting almost beside them.

This fact must have impressed the chairman of the A.S.M.E. Research Committee, Prof. A. M. Greene, Jr., who conducted the conference, when he made the remark that "a Research Conference such as this should be held at least once a year. Today is only a starter. Our Standing Research Committee of five is not able to do this kind of work; the committee is at present busy on such subjects as lubrication, bearing metals, flow of fluids, heat transfer, steam constants, permanency and accuracy of engineering instruments, vibration of shafting, torsional stress, vibration stress, friction of glass. These subjects represent particular phases only, though the whole field of mechanical engineering is open to the committee and the Society.

"The National Research Council feels that the Society ought to be available to furnish information on any branch of the subject, but only by a much larger committee organization than the present can this be done. Therefore the suggestion was that there should be a committee of about thirty-five, which would be a kind of subcommittee of the Research Committee, and an advisory committee to the National Research Council."

Throughout the proceedings of the conference there was no objection in principle to this kind of organization. It was felt, however, that the organization should be more or less informal and flexible, and formed with the idea that it could be made available to the National Research Council at any time upon its request.

Papers Presented and Discussed

To confine the discussion at the conference to definite subjects it had been arranged that four topics should be introduced. Two of these were technical papers: Elimination of Waste in Industry Through Research, by F. A. Wardenburg;[1] and Research in Leather Manufacture, by Arthur W. Thomas.[2] The other two were, respectively, Report of the Research Sub-Committee on Lubrication, and Discussion of Steam Table Research. While a number of valuable ideas were brought out in the discussions by the research specialists present, the account here given of the remarks made is confined as far as possible to the two things necessary for a successful liaison with the National Research Council: An indication of (1) the extent to which important work is being more or less duplicated in some other place; and (2) the probable degree of general publicity about research work in progress. The papers by Messrs. Wardenburg and Thomas are both condensed considerably to fit within the space of this special account of the Conference.

ELIMINATION OF WASTE IN INDUSTRY THROUGH RESEARCH

By F. A. WARDENBURG, WILMINGTON, DEL.

The prime object of business is the making of money, and if research work is to maintain its proper place in business, it must be conducted so that it will more than pay its way.

Perhaps in no other work is it more difficult to foresee the difficulties liable to be encountered, and research work is always approached in a spirit of optimism. As a consequence, the cost is almost certain to be underestimated, not infrequently as much as 50 per cent, and the saving is very liable to be overestimated. As the work progresses the solution of the problem seems always just "around the corner," and more and more expenditure is incurred until the final cost may be greater than the saving effected. This is particularly true of the development of new machines or processes, but to almost as great an extent with an improvement to something existing. The result may be that the research, instead of decreasing waste, adds to it.

From the standpoint of the permanent success of research work, every possible means should be adopted at the inception of a problem and at all times during its progress to make the proposition a commercial success.

As one of the methods of assisting in this, the following plan of a large corporation is outlined:

1 When it is desired that a research problem be undertaken, it is required that there be filled out an "Experimental Request Form" giving

- *a* Title of research problem
- *b* Process affected and plants to which applicable
- *c* Reasons for conducting research
- *d* Description of process or machine in use which research work is to improve or replace
- *e* Description of proposed improvement and how to be obtained
- *f* Estimated cost of research work
- *g* Estimated savings or other advantages, given in detail to show clearly how saving has been figured and estimated capital expenditure necessary to put results into production
- *h* Name of persons making suggestion or contributing major ideas
- *i* Necessary approvals by executives authorizing the work.

It is surprising the many research problems which seem very promising when discussed in abstract, but which fail to pass the test insured by the filling out of the above form.

2 The man having charge of the research is required once a month to make a complete review of the problem, stating:

- *a* Object of the investigation
- *b* Work accomplished during past month
- *c* Status of problem to date
- *d* Probability of successful outcome and any new developments having a bearing on the application of the work commercially, if successful
- *e* Further work proposed in immediate future.

---

[1] Asst. Chief Engr., E. I. du Pont de Nemours & Co., Wilmington, Del. Mem.Am.Soc.M.E.

[2] Asst. Prof. Food Chemistry, Columbia University, New York, N. Y.

3 Where it is apparent that the cost of conducting a research problem may be greater than the appropriation, an additional appropriation must be secured, at which time the commercial status of the entire subject is reconsidered by the executives to determine whether the expenditure of the additional money is justified. If not, the study is discontinued.

4 At the conclusion of a research problem, a complete report is made, in which is included the estimated figure on capital expenditure necessary and the savings and other advantages to be gained by the application of the results obtained to regular production so that, if justified, the research work may be turned to profit as soon as possible.

This plan of conducting research work lays continual stress on the *commercial* outcome. At every angle the question is asked, "Is the cost of this particular step justified by the results to be obtained from it?"

Suggested Coöperative Plan

Many companies in different lines are carrying on research work, each on problems in its own line. There are, however, many problems which should be studied but which are not receiving the attention they deserve because they do not present sufficient probability of making a satisfactory monetary return to justify any one company proceeding with the work.

Much research now done by manufacturing companies has to do only with that part of the subject which is of direct interest, frequently the effect of one or more of the variables is not determined, and frequently also, the study is only conducted to obtain a part of the curve. Further, there is a great deal of research work, of great importance to industry, but which is not done because it is seldom that any one company can justify conducting an abstract scientific reseach with the hope that the result of that research can be profitably applied to its business in some way.

True, a great deal of such work is being done by the universities or similar institutions, and some of it by the Bureau of Standards and other departments of the Government. The governmental departments, however, cannot be altogether depended upon because of the difficulty of securing the necessary appropriations. This kind of research work in the universities must necessarily show slow progress because it must be carried on during the spare time of the member of the faculty who is working on it, and it is difficult for a man engaged in university work to have the perspective necessary to obtain the results in the way most suitable for commercial use. Further, the problem selected to be worked upon depends upon the desires of the man who happens to have the opportunity and desire for research work, and is not determined as it should be from a broad viewpoint to insure that the most important subject receives earliest attention.

How much better it would be if a fund could be collected by subscription from manufacturing companies and others interested, and this fund placed under the control of some central body, such as the Research Committee of The American Society of Mechanical Engineers, which would fix a program of research work to be conducted, the place where the work should be done, and the methods to be followed in doing it.

With such a plan, information very necessary to industry would be obtained many years sooner than under the haphazard plan now followed. More complete and scientifically accurate information would be obtained, and the results would be much more widely distributed and made available for industry. As is quite important also, the total cost to industry would be very much less than where many concerns duplicate effort, as is now being done. To accomplish the best results, such a fund should be a continuing one, so that a program could be adopted for several years' work.

The American Society of Heating and Ventilating Engineers has had such a plan in effect for the past two years, with subscriptions amounting to $25,000 per year for five years. The coöperation of the U. S. Bureau of Mines was secured, and the Bureau loaned excellent laboratory facilities in the fuel-testing station at Pittsburgh. This latter is equivalent to approximately $20,000 per year, so that the equivalent of $225,000 is available altogether in this instance. An excellent technical staff is employed and good progress has been made. The work is directed by the Research Bureau of the Heating and Ventilating Society.

With the wide field covered by the A.S.M.E., no difficulty should be experienced in raising a similar fund, ample to carry on an ambitious research program and secure data of inestimable value to industry. Some of this research would be carried on in a laboratory to be financed and controlled by the committee directing this fund, and some of it at universities, the necessary financial assistance being provided from the fund. This would also increase the scope of the research work which the universities could carry on, as the necessary financial support would be easier to secure.

RESEARCH IN LEATHER MANUFACTURE

By ARTHUR W. THOMAS, NEW YORK, N. Y.

The art of leather manufacture is a glaring example of the need for scientific research, and if conditions in some other industries are comparable with those of the tanning industry, it is time that attention is given to publicizing the research which has been done, if only to show the small amount of accurate scientific data upon which these industries are based.

In the average tannery the majority of the operations conducted in transforming rawhide into finished leather are conducted in essentially the same manner chemically as they were centuries ago. Frightful "formulae" similar to "shot-gun prescriptions" of the old-school physicians have been jealously guarded in the tanneries and have been handed down from generation to generation.

The point of view is usually that since good leather was being made in 1000 B.C. or 1776 A.D., why bother about scientific research? This impedance in the leather industry will soon be overcome by competition.

To give an example, the foul practice of bating with dungs is still to be found in many tanneries, though it has been found that artificial bates can be prepared with the necessary proteolytic enzyme in the dungs—and even the value of the presence of pancreatic enzyme is now questioned.

Fundamental advances in the science of leather formation have been made in the last few years, and he who can understand the new chemical thermodynamic theory of Proctor and his students, notably Wilson, can safely discard all his old rule-of-thumb methods and feel sure in advance just what is going to happen in his processes.

Many other examples might be given. Stasny's studies of limings have proved that the old idea of necessity for the presence of ammonia in lime liquors was unfounded, and that the factors which count are regulation of alkalinity and proportions of sulphide.

Studies of the combination of chrome and collagen have prevented the running of tons of chrome into the sewers because of lack of knowledge of the reaction forming the insoluble impurtrescible chrome-collagen compound. And so on.

Instances in which mechanical engineering has improved the efficiency of leather manufacture are numerous.

The designing of extractors and vacuum evaporators has made possible the manufacture of concentrated vegetable extracts permitting quicker tanning and eliminating the expense of freight on barks.

Machinery for unhairing, fleshing and shaving hides have eliminated much hand labor, although there has not as yet been invented a machine which will completely dehair.

Large mechanical rocking systems have improved the liming operation.

Since animals are raised primarily for their meat and wool, tanners are obliged to use a by-product as their raw material, often under great handicaps. Disease in the animal, admittedly fatal in the meat industry, is also a serious factor to the tanner.

The warble fly problem has been acute. This insect deposits its larvae in the hide of the animal, which becomes filled with holes. The only preventive so far is to watch the live cattle and remove the pest by hand.

To summarize, there is a great field in the tanning industry, by the prosecution of scientific research, to eliminate the unnecessary wastes due to lack of knowledge of the reactions and hence waste of time and materials. Further, publication of the knowledge already available will do much to produce a better product, and make it available at a better price, restoring leather to the point at which it can successfully compete with other materials.

RESEARCH PROBLEMS DISCUSSED

THE first paper to be discussed was that by Mr. Wardenburg. The idea that the DuPont Company insisted on the promise of profit before it gave approval to research, was a surprise to M. C. Stuart,[1] and he thought it would be to others. On the other hand, C. E. Lucke[2] thought that this was the most important paper of its kind he had ever heard. Whether it expresses the correct ideal or not, he did not think as important, as the fact that it could be expected that the maximum research would be done by business corporations.

Dr. Lucke thought that one of the most valuable contributions a Research Conference can make is a classification of research. In such a classification the most important kind is that of improving commercial products.

Albert Kingsbury[3] thought that too close a scrutiny of research subjects sometimes hid things which would otherwise come to light. Further, things set forth as objects in research are often not obtained, but on the other hand, by-products sometimes turn up of a value often exceeding the primary object.

L. F. Lyne, Jr.,[4] continued on the line of Mr. Kingsbury's remarks, and added from his personal experience with lubricants.

F. A. Wardenburg, in closing this part of the discussion, said that most firms finding it necessary to earn a maximum return on their capital were not carrying on research. However, he felt that such concerns would be glad to contribute to some coöperative program, carried out under proper auspices and including subjects in which they were interested.

A Familiar Research Discussed

To bring out ideas of value to the conference, the chairman called on Prof. H. F. Moore, of the University of Illinois, well known in connection with the investigation there of fatigue of metals, or, as Professor Moore put it, "progressive failure of metals under continuous stress."

In describing the scope of the problem, Professor Moore characterized it as "involving much indefinite research into first principles, whose outcome could not be seen."

The National Research Council first saw the problem, and secured a large grant of funds to carry on the investigation. The Engineering Experiment Station at Illinois contributed the laboratory apparatus and also Professor Moore's time. One large commercial company found the apparatus and organization could be effectively utilized for certain work it wanted done.

The work therefore represented a measure of coöperation between the National Research Council, the Engineering Foundation which supplied the money, the Experiment Station at Illinois, and one commercial company.

The Research was carried out under a definite agreement, and the University charged a price. An interesting part of the agreement was that the data of the entire investigation should be open at any time to any interested party.

To his mind, this research pointed out the value of coöperative investigation between quite widely different interests. He saw no reason why such an arrangement should not be duplicated elsewhere.

Both Mr. Flinn and Dean C. R. Richards[5] called attention to the fact that though this investigation has been completed, the apparatus is still available to any industries which might want to use it. Dean Richards put it that it would be unfortunate if this laboratory, now brought to a proper degree of efficiency, were disbanded before it had gathered in the knowledge not only of ferrous, but of non-ferrous, metals. Dean Richards called attention to one fundamental condition—that the obligations of the University to the public compel it to own and control the first right of publication. He thought it a great mistake when such institutions keep their results secret.

Dean Richards thought that in the long run the more complete our knowledge of science in its application to industry, the greater the confidence of the people in using the products of industry. So that the idea that research must be kept for a secret use, and to keep competitors from meeting competition, is entirely wrong.

A Small Beginning Develops Into Big Work

Dean Richards also cited the research at Illinois, in connection with the National Warm Air Heating and Ventilating Association, into house-heating furnaces. In the beginning, while the members of the association thought the research would be good, especially good, advertising, they had no conception of the results to be obtained. Now, as the work has gone on for four years, their attitude is entirely changed, and they want it continued until nothing more is to be gotten out of it.

Secrecy of Experiments Undesirable

An interesting sidelight on secrecy was exposed by E. J. Prindle,[6] who said that not only was it an altruistic thing to reveal secrets of research, but it was a dangerous thing not to reveal them from the standpoint of the Patent Law. The law sustains the man who first discloses the discovery, and not the man who first makes it. The object of the Patent Law is to help the man who not only makes an invention, but who discloses it to the world so that it may become public property after a given period of protection to the inventor.

L. F. Lyne, Jr., gave an example of costly duplication of effort resulting from violation of the principle which Mr. Prindle pointed out. One concern had spent $300,000 in developing a certain product and putting it on the market, while another concern located not very far away was carrying on exactly the same investigation.

The product was a lubricant, and apart from the number of commercial concerns there are at least four societies—all represented at the conference—giving their attention to lubricants. As he understood it, one of the purposes of the National Research Council is to bring together such interests as these.

Mr. Flinn replied to Mr. Lyne that such was one of the functions of the Council. He could give good examples of such service in the iron and steel industry, the welding industry and others.

Work of the A.S.H. & V.E. Described

Dean Anderson, research director of the American Society of Heating and Ventilating Engineers, showed how in research starting out for one thing often led to searching for others. Their work at the Bureau of Mines Laboratories in Pittsburgh started out with the goal of finding the relationship between air temperature and humidity and air motion—a thermodynamic problem. Soon it developed into research on some fundamental laws of the cooling powers of vapors. The effort on the human body turned the problem into a physiological one and brought in the Bureau of Health.

Primarily the work of the laboratory has been to take the numerous problems presented by the manufacturers, and from them determine the fundamental relationships.

With regard to publicity, he expected that we were doing things today that the Chinese did two thousand years ago—doing them again because the Chinese left no record of how they were done. With this experience, there is a tendency now for no one to keep from the scientific world anything he may find out.

Advocates a National Laboratory

In calling attention to the amount now spent by the A.S.M.E. annually for research, Dean Anderson asked if more money could not be appropriated. He thought the Society should establish a research laboratory like those at Illinois University or Pittsburgh. He regarded such a plan as the foundation of the Society—not to collect data about the isolated pieces of research going on about the country, but to have a real research laboratory for the general sciences.

[6] Patent Attorney, Prindle, Wright and Small, New York, N. Y. Mem. Am.Soc.M.E.

Professor Matthews and Dean P. F. Walker both endorsed the laboratory idea. Dean Walker said that the discussion had taken a turn which had been in his mind for years, especially in connection with oils and lubrication. He happened to be a member of the A.S.T.M. Committee on Lubrication, and seeing the report of the A.S.M.E. Committee on Lubrication on the program, he wondered whether there were any connection between the two organizations.

This was a cue for the presentation of the Report of the Sub-Committee on Lubrication, and Professor Greene therefore called for it.

A.S.M.E. WORK IN LUBRICATION

In presenting this report, Albert Kingsbury said that it was simply one of progress for the past year. The committee was organized five or six years ago, and at that time, from a general survey of the situation it was decided for the present to deal with the absolute fundamentals of the subject only.

Practically everything we know about lubrication has been evolved in the last forty years, and one problem—that of the conditions existing in the ordinary bearing under normal conditions—had practically monopolized all activity in this line.

The ideal condition in a bearing is one in which the film of lubrication should be of measureable thickness, and should separate the component parts of the bearing so that the frictional resistance is transferred from the metal and becomes entirely fluid friction.

It has been known for a number of years that the ideal condition is subject to treatment by theory, and definite formulas have been evolved so that fairly accurate predictions can be made.

It is well understood that the property of a lubricant maintaining its function is viscosity. Another important property is "oiliness," which for some reason unknown so far seems to be greater in the organic than in the mineral oils.

The work of the committee has been devoted to carrying on experiments on oils under high pressures, up to 44,000 lb. per sq. in., and the results so far justify going to still higher pressures. Having obtained some indication as to what happens at 3000 atmospheres the committee is anxious to find the conditions at 30,000 atmospheres, and hopes to do so later on.

PROGRESS IN STEAM-TABLE RESEARCH DESCRIBED

By a fortunate coincidence there were brought together at the conference Mr. George A. Orrok, who induced the A.S.M.E. to accept the administration of a fund subscribed by the industries to make a research into the upper limits of the steam tables and establish fundamental constants, Professor Greene, under the auspices of whose Research Committee the technical work was being done, Dr. S. W. Stratton, Director of the Bureau of Standards, which has carried out some of the investigations, and Dr. H. N. Davis, of Harvard University, in whose laboratory another part of the experimental work is being done.

From the information given by these four gentlemen the meeting obtained a very good idea about how this work was being financed and how administered, how far the experimental work had proceeded, and what were some of the difficulties.

Doctor Davis gave a popular conception of what it meant to "try and get something on the Thomson-Joule effect." Then he turned to Dr. Stratton and told the meeting what it meant to "try to get something out of the Bureau of Standards"—how the Bureau would reply to letters and say that "progress was being made," whereas detailed inquiry would reveal that the Bureau had had several of its best men on the job for some time.

Doctor Davis thought that all in all, the probability of completing this fundamental piece of research work was "very hopeful."

A. D. Risteen[1] endorsed Doctor Davis' experiences of the difficulties of doing this kind of work. He also congratulated the Society for having taken it up, characterizing it as a "public scandal" that this one fundamental thing in the whole subject of accurate thermal work had not been done before. A full account of this research has already been published in Mechanical Engineering. Mr. Orrok then detailed the progress in collecting the funds.

Mr. Rice, the Secretary, here suggested the organization of a permanent committee to devote itself especially to this particular piece of research, and this was accepted, the Committee to be appointed by the Council of the Society on the recommendation of the Research Committee.

A SESSION ON FUEL ECONOMY

(Continued from page 113)

equipment of certain installations referred to by the author but not mentioned by him. While the conclusions drawn were correct, he said, all the facts should be known.

Edward N. Trump said that he had had the unique experience of buying boilers from the same company for forty years, which had given him an opportunity of seeing whether or not it paid to economize. By replacing at a cost of about one million dollars an equipment of boilers of from 12,000 to 15,000 horsepower with which an efficiency of 70 per cent was obtainable with an equipment capable of 80 per cent efficiency, the cost of the investment was saved in five years.

David Moffat Myers gave some actual figures of savings with the investment costs involved which has come under his observation.

R. L. Beers[20] presented a written discussion of the savings to be made with the use of stokers applied to small hand-fired boilers.

Gas Producer Problems Discussed

Walter W. Oakley[21] said that the greatest problem in the operation of the producer is labor turnover. Mechanical producers are a help, but even mechanical producers require an attendant. Costs for gasifying a ton of coal in a hand-poked producer are about one dollar, while in a mechanical producer they are about 15 cents these figures being for labor charges. The costs of the mechanical producer can be equaled with hand-poked producers if it is possible to keep trained men on the job.

Earle E. Adams[22] spoke of the use of tar extractors and the returning of the tar to the producer to be gasified. He thought the Fuels Division should give more thought to the use of gas, while J. H. Taussig[23] said he thought the Division should give more attention to the use of fuel for industrial purposes.

Edward N. Trump said that the paper had not considered the recovery of sulphate of ammonia and other products from coal. He had built a plant consuming about 100 tons of coal in which 80 lb. of sulphate of ammonia was obtained per ton of coal.

Jas. H. Matherson[24] presented a written and illustrated discussion on improvements in gas equalizers and soot collectors for gas producers, installed in the tube works of the Reading Iron Co., Reading, Pa. The advantages claimed as a result of these improvements are a saving in fuel of 20 to 25 per cent, an increased product of improved quality, a saving in gas valves, brickwork, labor, machine-shop repairs and cleaning out of soot, more continuous operation of furnaces and more contented workmen.

J. Frank Rogers,[25] in a written discussion, set forth sixteen requirements for a gas producer.

A Correction

In Mr. A. L. De Leeuw's discussion of Mr. Polakov's paper, on page 17 of the January issue, second column, eighth line, the word "demoralization" should have been "democratization". The error was unfortunate, as it was possible to publish only a brief mention of Mr. De Leeuw's comprehensive and meritorious discussion, and quite a misleading conception of his ideas was conveyed.

SURVEY OF ENGINEERING PROGRESS

A Review of Attainment in Mechanical Engineering and Related Fields

The Flow of Air and Steam in Nozzles

Note on the Flow of Air and Steam in Nozzles, Gerald Stoney and Norman Elce. It is now generally recognized that steam when expanded rapidly, as in turbine nozzles, becomes supersaturated provided that the initial superheat is not so high that the steam remains superheated throughout the expansion. Whether any condensation takes place before the nozzle throat is not so definitely known, but some evidence on this point is afforded by the following note on discharge coefficients.

If the theory of supersaturation be correct, the expansion of steam through a nozzle is so rapid that condensation cannot take place down to a pressure below the critical pressure, so that down to the throat the steam expands as a perfect gas. The law of expansion is then:

$$p\,(V-b)^{\gamma} = \text{a constant} \ldots\ldots\ldots\ldots\ldots\ldots [1]$$

where γ = 1.3
p = absolute pressure
V = specific volume
b = co-volume, taken as the specific volume of water at 32 deg. fahr.

The co-volume b is only 1 per cent of the specific volume V at pressure $p = 300$ lb. per sq. in. and neglecting this the maximum theoretical discharge of steam through a nozzle may be shown to be

$$q_{\text{max.}} = 0.3155 a_t \sqrt{\frac{p_1}{V_1}} \text{ lb. per sec} \ldots\ldots\ldots [2]$$

where

$q_{\max}$ = maximum theoretical discharge, lb. per sec.
a_t = nozzle throat area sq. in.
p_1 = initial pressure, lb. per sq. in.
V_1 = initial volume, cu. ft. per lb.

The effect of the small term b neglected here is only 0.274 per cent of the discharge at a pressure $p_1 = 300$ lb. per sq. in. abs. The value of V_1 to be inserted in Equation [2] is in each case the specific volume of the steam at inlet, whether superheated or wet.

For saturated steam, Equation [2] may be written in the convenient form:

$$Q_{\text{max.}} = M_1 a_t p_1 \text{ lb. per hr} \ldots\ldots\ldots\ldots\ldots\ldots [3]$$

where:

$Q_{\max}$ = maximum theoretical discharge, lb. per hr.
M_1 = a constant depending upon p_1 and upon the index in the adiabatic equation, which is here taken as 1.3, the value for dry steam.

Rateau (Réchérches experimentales sur l'ecoulement de la vapeur d'eau) measured the discharge of saturated steam through convergent nozzles, and found the empirical equation:

$$Q_{\text{max.}} = 3600\,(15.26 - 0.96 \log p_1)\, a_t p_1 \text{ gm. per hr.} \ldots [4]$$

where

a_t = sq. cm.
p_1 = kg. per sq. cm.

In English units this becomes:

$$Q_{\text{max.}} = 3.456\,(17.05 - \log p_1)\, a_t p_1 \text{ lb. per hr.} \ldots\ldots [5]$$

$$= M_2 a_t p_1 \ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots [6]$$

where

a_t = sq. in.
p_1 = lb. per sq. in.
M_2 = a constant depending upon p_1.

Table 1 shows values of M_1 for $\gamma = 1.3$ (the index for dry steam) and $\gamma = 1.135$ (the index for saturated steam), and of M_2 for various values of p_1.

If the limit of the supersaturation condition is such that no condensation occurs before the throat, the ratio $\dfrac{M_2}{M_1(\text{for } \gamma = 1.3)}$ is the coefficient of discharge C_d for saturated steam in Rateau's convergent nozzles, and this should then be of the same order in this case as for any perfect gas, such as air or highly superheated steam, through similar nozzles.

Table 2 shows the comparison of the coefficient $\dfrac{M_2}{M_1\,(\text{for } \gamma = 1.3)}$ with

1 The coefficient of discharge of air through a convergent nozzle from the experiments of T. B. Morley (Proc. I.Mech.E., January, 1916).

2 The coefficient of discharge of highly superheated steam through a convergent nozzle from the experiments of A. L. Mellanby and W. Kerr (Trans. Inst. Engineers and Shipbuilders of Scotland, December, 1920).

TABLE 1

p_1	300	250	200	150	100	50	14.689	10	5	1
M_1 $\gamma = 1.3$	52.12	52.39	52.73	53.16	53.83	55.02	57.25	57.93	59.46	62.34
M_1 $\gamma = 1.135$	49.64	49.91	50.22	50.63	51.23	52.41	54.54	55.22	56.64	59.33
M_2	50.37	50.65	50.98	51.42	52.02	53.06	54.90	55.49	56.52	58.93

TABLE 2

			Initial Pressure, Pounds per Square Inch Absolute.						
Medium	Reference		150	100	75	50	25	10	1
Saturated steam	Rateau	C_d	0.967	0.966	0.965	0.964	0.962	0.958	0.945
Steam at 250 deg. fahr. superheat	Mellanby	C_d	...	...	0.975	...	...	...	...
Air	Morley	C_d	...	...	0.97	0.97	0.97	...	...

It is thus seen that the coefficient of discharge for saturated steam is, according to Rateau's tests, slightly less than that for air and superheated steam, which are about the same. On the other hand, Rateau's nozzles were not all so well shaped as those tested by Mellanby and Morley, so that the evidence, although not quite conclusive, is that there is little or no condensation in the expansion of saturated steam in a nozzle down to the critical pressure ratio. It would be an interesting investigation to determine the coefficients of discharge for steam initially wet, saturated and superheated, and for air, through the same nozzle, and thus determine whether there is any condensation before the throat with wet or saturated steam. So far as the above evidence goes, there is no such condensation and saturated steam acts down to the throat as a perfect gas with an adiabatic index of 1.3. (*Engineering*, vol. 112, no. 2918, Dec. 2, 1921, pp. 750–751, *tA*)

Short Abstracts of the Month

AERONAUTICS (See also Internal-Combustion Engineering)

Bristol Gas Starter for Aero Engines. Description of a starter made by the British Aeroplane Co. in England for the Jupiter aero engine, but applicable to many other makes. This starter, the Bristol, consists of a small two-stroke, air-cooled, single-cylinder gasoline engine whose crankcase is mounted on to a pumping cylinder. The latter draws a combustible mixture from the carburetor, supplies the power cylinder, and pumps the mixture under pressure to the main-engine cylinders. Interposed between the pumping cylinder and the main-engine cylinder is a

small disk-valve distributor driven at half engine speed from the main engine, which passes the compressed explosive mixture to the main-engine cylinders in the proper sequence. The mixture is admitted on the firing stroke and also on part of the induction stroke. In order to avoid loss of pressure through the open inlet valves on the induction stroke, the port in the distributor which is in communication at this period is controlled by a spring-loaded ball valve arranged to open at a pressure of about 40 lb. The gas cylinder is fitted with a two-cylinder magneto from which one ignition lead is taken to the spark plug of the two-stroke upper cylinder, while a second is taken to the central terminal of the distributor on one of the main-engine magnetos. When the two-stroke engine is started, explosive mixture is supplied to the main-engine cylinders under pressure, and the main engine begins to turn. At the same time gas is admitted to the cylinders so that after one complete revolution of the main engine the entire induction system is filled with gas which is drawn in on the next induction stroke.

If, now, the short-circuit switch between the starter and magneto and the main-engine magneto is opened, the engine will begin to fire and pick up on its own carburetors. The gas-starter throttle supplies both gas and ignition to the main engine for starting, and, in addition to its function as a starter, can be used for driving wireless generators, etc.

It is stated that the Bristol starter has started a Jupiter engine from cold in 17 sec., and when hot in 2 to 3 sec. It has turned over a 500-hp. engine cold at 12 to 15 r.p.m., and has maintained a gas pressure of 140 lb. per sq. in.: it weighs complete 40 lb. The article does not give specific data as to how in actual service the starter is controlled from the aviator's seat. As the normal power of the Jupiter engine is 345 hp., the weight of the starter is only a little in excess of 0.1 lb. per hp. (*Flight*, vol. 13, no. 48/675, Dec. 8, 1921, pp. 802–803, 2 figs., *dA*)

AIR ENGINEERING (See Steam Engineering)

CORROSION

Colloidal Theory of Rust, Dr. Newton Friend. Abstract of a lecture before the Birmingham Metallurgical Society on Recent Progress in the Study of Corrosion. The author is head of the Chemistry Department of the Birmingham (England) Municipal Technical School.

After examining various theories to account for the phenomena attendant upon corrosion, Dr. Friend directed attention to the "colloidal theory" which had been formulated by himself, and which, he said, reasonably accounted for the facts. If moving water was increased to a velocity of eight miles per hour, no corrosion of immersed metal took place. According to the colloidal theory, corrosion of iron in a neutral solution of water was entirely distinct from corrosion in acid. Iron first passed into solution through the presence of electrolytes, gradually developing a solution of ferrous hydroxide, which eventually produced oxidation. The solution, however, could be removed by rapidly flowing water, thus inhibiting corrosion. The same retardation could be effected if the colloid was coagulated either by physical or chemical precipitants.

Particulars were given of various experiments made to test the theory. Solutions containing alcohol reduced rust relatively to the increase in alcohol.

On the question of the effect of temperature on the rate of corrosion, practically nothing was known. But experiments had shown that at 80 deg. cent. iron corrodes nearly ten times as rapidly as at 0 deg. The effect of light was very remarkable. Light was shown to accelerate corrosion very markedly, even after the temperature effects had been removed. Corrosion was clearly affected by barometric variation. The subject was very complex, and the results were not always the same, even when experiments were carried out under what appeared to be exactly identical conditions. The lecturer expressed the hope that further experiments would indicate the bearing of the colloidal theory upon the corrosion of ferrous alloys and non-ferrous metals. (*The Iron and Coal Trades Review*, vol. 103, no. 2805, Dec. 2, 1921, p. 793, *t*)

ENGINEERING MATERIALS (See also Corrosion)

New Etching Mediums for Steel. Dr. A. Fry described in a German periodical *Stahl und Eisen*, Aug. 11, 1921, a new etching method consisting essentially of a strong acid solution of copper chloride over a properly prepared steel.

The new medium reveals in details the strain lines in a low-carbon steel as distinct from the actual crystalline pearlitic or other structure. In other words, it permits locating alterations in the body of steel caused by stress. In this connection mention is made of an experiment recently conducted by a large eastern railroad, the results of which are in good accord with those obtained by the German method. Thin strips of highly polished low-carbon steel were laid on the surface of the rail, over which the locomotive wheel was allowed to press gently. It was found that there resulted in the strips a distinct set of lines entirely different from anything encountered previously. It is now found that these lines bear a close resemblance to the strain lines brought out in one of the pieces of German steel. (Editorial in *Iron Age*, vol. 108, no. 23, Dec. 8, 1921, pp. 1488–1489, *g*)

Plastic Wood. A new material manufactured by a British concern, namely, a collodion preparation made with very fine wood meal, and as supplied ready for use of the consistency of soft putty.

This material will probably be of most interest in connection with patternmaking and molding, for it can be used for ordinary filling and stopping work in wood patterns and for fillets. It adheres firmly to wood and can be applied and smoothed down by the thumb or a tool. It is claimed to be waterproof, to set quite hard, and can be cut with an ordinary tool like wood and turned in the lathe. It can also be finished with sandpaper. It shrinks slightly in drying but the hardened material is not brittle and nails can be driven firmly into it without cracking it. A solvent is also available to soften the material. (*Engineering*, vol. 112, no. 2919, Dec. 9, 1921, p. 785, *d*)

Wire Cables and Weathering. Taking advantage of the rewrapping of the cables of the Williamsburg bridge over the East River at New York City now in progress, Edward A. Byrne, chief engineer of the Department of Plants and Structures of the City, has been carrying on an examination of the condition of four $18^5/_8$-in. cables of the structure. The sections inspected had the interspaces between wires fairly filled with slushing oil supplied when the cables were constructed (1901–1902) and no signs of corrosion were visible, except for a few spots of discoloration on the outer layer of wires. In the main span, rust discoloration on the outer wires was found at a number of places.

On the Manhattan bridge the cable bands have given some trouble from slipping. This defect has been remedied by modification of details of the cable bands. When slipping occurred the wrapping wire covering the cable between the bands became disarranged and the cable wire was exposed, making prompt replacement of the bands necessary. In such replacement the band is set back to its proper position and a short section of the wire wrapping to either side of the band is renewed. Before this is done, however, the cable wires are wedged apart and the interior examined.

Still better conditions have been found in the wire-wrapped cables of the Manhattan and Brooklyn bridges. There the wires which are galvanized have in no cases shown any rust. The condition of the structural steel of the Williamsburg and Manhattan bridges was also examined and found to be surprisingly good. Although repainting has been done at intervals of as much as eight or nine years, no structural parts of either bridge have suffered from rust. Except for thin metal in some railings and floor grills, the steel work of both structures is considered to be in perfect condition. (*Engineering News-Record*, vol. 87, no. 23, Dec. 8, 1921, p. 939, *dg*)

Krupp Rustproof Steels, Fritz Huth. At the technical exhibition in Leipzig were shown some so-called "rustproof" steels made at the Krupp Works. These have been developed as a result of investigations carried out at that establishment during the

years 1909 to 1914 on the corrosion of steel, and belong to the class of chrome-nickel steels.

These steels may be divided into two classses. To the first class belong steels of high mechanical strength, while to the other belong steels characterized by high resistance to corrosion and wear. According to a paper by Dr. B. Strauss (*Krupp Monatshefte*, Aug., 1921) the first class of steel contains from 10 to 15 per cent chromium and from 6 to 10 per cent nickel. The steels of the first class belong to the type of self-hardening steels, while the second, if heated to 1100 or 1200 deg. cent. and slowly cooled down, are machinable and tough. Steels of the first class are magnetic and those of the second non-magnetic. In order to produce these steels a carbon-free chromium must be used. It may be obtained either by the aluminothermic process or produced from chromium refined in an electric furnace. Such chromium is, however, expensive, which makes the corresponding type of steel also quite costly, namely, 12 to 15 times as high as ordinary steel. (*Metall-Technik*, vol. 47, no. 17, Nov. 1, 1921, p. 123, *d*)

Tensile Properties of Some Structural Alloy Steels at High Temperatures, H. J. French. The report gives results of determination of tensile strength proportional limit, elongation, reduction of area and strength at fracture throughout the range 20 to 550 deg. cent. for four steels containing about 0.38 per cent carbon, as follows: (*a*) plain carbon steel; (*b*) $3^1/_2$ per cent nickel steel; (*c*) 3 per cent nickel, 1 per cent chromium steel; and (*d*) 1 per cent chromium, 0.2 per cent vanadium steel.

Brief reference is made to the type of fractures obtained in testing steels at various temperatures and particular attention is paid to comparison of the tensile properties of these alloys at 550 deg. cent. in the neighborhood of which various parts of converters are subjected to stresses in production of ammonia by the Haber process.

Of the four steels tested in normalized condition it appears that the two alloys containing chromium show greater resistance to weakening by increase in temperature to about 550 deg. cent. than either the plain carbon or $3^1/_2$ per cent nickel steels, and at this high temperature the chromium-vanadium steel is to be preferred from the standpoint of high tensile strength and limit of proportionality.

The carbon and $3^1/_2$ per cent nickel steels behave alike with rise in temperature above that of the room, and at about 550 deg. cent. the addition of $3^1/_2$ per cent of nickel appears to have little or no effect on the tensile properties of the carbon steel. (Abstract of *Technologic Paper of the Bureau of Standards*, No. 205, *e*)

Cutting Fluids

Cutting Fluids, Eugene C. Bingham. Machinists have long recognized lard oil as being wellnigh indispensable in certain cutting operations, whereas for the majority of operations in the machine shop much cheaper oils may be used to advantage. The reasons for the superiority of lard oil have not been clearly understood but they turn out to be closely related to the general theory of lubrication, and with the development of fast-moving machines this theory is of vast economic importance.

Theory. One function of a cutting fluid is to cool the work, and for this purpose water with its high specific heat is suited. But since water tends to rust the machines, alkaline substances are added such as soda or soap.

In difficult cutting operations, the chip is apt to "seize" the tool, causing dulling of the tool, roughness of the work, etc., hence it is inferred that in such cases a good lubricant is required and therefore water is out of place.

The experiments of Tower led many to the erroneous belief that two oils of the same viscosity would have the same lubricating value. Consequently the cheaper mineral oils have been regarded as equivalent in every respect to the fatty oils which they once supplanted. There are certain operations in the machine shop such as the threading of micrometer screws, parting off mild steel, threading and tapping wrought iron, boring gun barrels, in which no mineral oil, regardless of its viscosity, will produce the excellent results obtained with lard or other fixed oils. With lard oil, the surface obtained is smoother, the chip is less serrated and longer and the tool lasts longer; further, the production is increased, there is less heating, and, finally, the machine runs steadier.

It appears that whenever two *clean* surfaces of metal are brought together they tend to seize. Many examples prove that a quite invisible layer of impurity will prevent seizure. The clean metal of the chip moving over the face of the tool under great pressure affords a peculiary difficult problem in lubrication. Lard oil has a much higher *adhesion* for metal than have the pure mineral oils. It is drawn in between the chip and the tool and forms a strong film which prevents the chip from adhering to the tool and forming a 'bead." Other oils containing fatty acids, or groups of atoms with "residual affinities," such as sperm oil, castor oil, rape oil, etc., have in large measure the advantage of lard oil.

It seems readily possible to improve mineral oils as cutting fluids and as lubricants by adding liquids of high adhesion such as oleic acid, pine oil and fixed oils. Methods are suggested for the measurement of adhesion. While this paper was in course of preparation, the Deeley friction-testing machine and the Lanchester worm-gear machine were being developed in Great Britain, which demonstrate the superiority of the fixed oils as lubricants and the advantage of adding fatty oils of their acids to mineral oils to be used as lubricants.

Practice. Correspondence with the large machine shops in America with regard to their practice in the use of cutting fluids elicited information worthy of record.

The purposes of cutting fluids are to cool the work, lubricate, lessen wear, insure a good finish with accurate dimensions, wash away chips, and prevent the formation of dust. The materials used may be classified as (*a*) oils, (*b*) air, (*c*) aqueous solutions and water, and (*d*) emulsions.

Oils may be animal oils, fish oils, vegetable oils, mineral oils or compound oils. The edible animal oils are too expensive to use as a lubricant hence only the inferior grades are used for this purpose. Fish oils are objectionable unless deodorized, vegetable oils tend to gum, and mineral oils are low in adhesion and are therefore poor lubricants. Compound oils are largely used, containing a large percentage of mineral oil with a smaller percentage of vegetable or animal oil, or a mixture of both. Air is used merely to remove chips.

Water alone is used to some extent, but on account of the tendency to rust, soda, sodium silicate, sodium resinate or other soap are usually added.

Emulsions have the advantage of cheapness while possessing much better lubricating properties than the aqueous solutions. They are of three types. Mineral oil compounded with neutralized sulphonated oil will form a permanent emulsion when mixed with various proportions of water. Mineral oils are also compounded with an alcoholic solution of soap. A third variant is marketed as a paste, it being a thick soap solution with mineral oil added. The second type is the most desirable and the third the least so.

As to the choice of a cutting fluid for a given operation, the character of the operation performed has more to do with the choice of cutting fluid than the character of the metal. For drilling, reaming, milling, planing and sawing emulsions are generally satisfactory. For tapping and threading and parting off compound oils and lard oil are often resorted to. Compound oils are used with automatic screw-cutting machines.

The material cut is also of importance. There is a general consensus of opinion that soft steel and wrought iron are difficult metals on which to get a good surface without lard or sperm oils. They are called "draggy" metals. Cast iron, on the other hand, being brittle, does not adhere to the tool and no lubricant is required. Contrariwise, on a hard brittle steel, lard oil merely produces a "glaze" and turpentine is used with success.

The formulas of cutting oils used by large and successful users are given.

In the search for the true explanation of the remarkable "oiliness" exhibited by lard oil, the surface tension, specific gravity, and specific heat of several oils were studied by A. W. C. Menzies. The question of fluidity was studied by W. G. Kleinspehn. (Abstract of *Technologic Paper of the Bureau of Standards*, No. 204, *ep*)

FUELS AND FIRING

Powdered-Coal Burners and Dust Filters

Burning Powdered Coal in Arizona. Description of the plant of the United Verde Copper Co. at Clarkdale, Ariz., where it has been found that it costs less to burn powdered coal than fuel oil (per B.t.u.). In the dust separators muslin tube filters were used at first. The results obtained in keeping the plant free from dust and preventing dust losses from the main vent were highly satisfactory, but several fires occurred and burned out the muslin filter tubes. After this individual filters were placed over each auxiliary collector. These filters consisted of stacks with baffles and water sprays, the dust caught being washed into a pipe line carrying it back into the main coal-storage plant. This system eliminated fires, but allowed considerable dust to escape into the atmosphere. The losses are not, however, of especially great importance.

The original article gives a complete table of costs of preparing powdered coal for fuel, in which 98 cents is stated to be the operating cost per ton, and from 32 cents to $1.88 (depending on the size of production) the fixed charges.

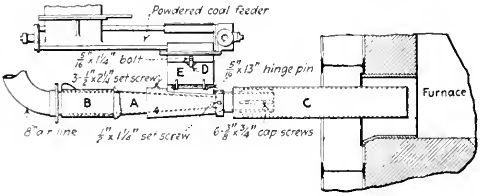

Fig. 1 Powdered-Fuel Burner Used at the Clarkdale Plant, United Verde Copper Co., Ariz.

The powdered-coal burners developed at Clarkdale are shown in Fig. 1. Blower air is delivered through an 8-in. (20.3 cm.) duct to each burner. Coal dust is fed from the 4-in. (10 cm.) screw overhead through the vertical chute *E* on to the first air nozzle *A*. The first stage of induced air is drawn in around this nozzle and regulated by means of sleeve *B*, which slides back and forth over the pipe The second stage is induced in the burner pipe *C* after the coal dust has been fed into the air current. The burner pipe contains a fair mixture of powdered fuel and air which is introduced into the furnace through cast-iron burner ports. This mixture acts as a fluid and is under a pressure varying from 3 to 6 oz. per sq. in., (13 to 26 grams per sq. cm.) and contains approximately 85 per cent of the total air necessary for complete combustion. The remainder of the required air is drawn into the furnace through the furnace walls, burner ports, and other openings. (*Electrical World*, vol. 78, no. 23, Dec. 3, 1921, pp. 1121–1123, 1 fig., *dp*)

FOUNDRY

New Side-Blown Bessemer Converter

Side-Blown Bessemer Converters, T. Levoz. Very interesting historical account of the development of the side-blown bessemer converter, with criticism of the various types based largely on the personal experience with them of the writer, who was for many years chief engineer of a steel company in France.

From his many years of experience with converters, the author developed the one shown in Fig. 2, where *A* is the vertical and *B* the horizontal section of the converter. In the vertical section 1 shows the bottom of the reverse trunk shape, while 2 is the blast chamber proper *V* with the tuyere box *P*. As a matter of fact there are two tuyere boxes, *P′* and *P″*, which can be used alternately in order to permit the renewal of the air-drying material, such as pumice stone impregnated with sulphuric acid. *S* is a tap hole for removing slag as it forms during the period of elimination of silicon. The upper part 3 forms a dome, this particular shape being given to it in order that pieces thrown up from the bath shall collect there and return to the bath. The horizontal section shows the two bearings for tilting the converter. One of the shafts *T* is hollow to admit the air at the maximum pressure of the blower. A chamber *C* causes the air to go through a filter *F*, *F′*, containing dehydrating materials and hence to the tuyeres.

As regards the conditions of operation which would give a maximum of efficiency, it is stated that air from the blower issuing under a pressure of 40 to 50 cm. of mercury goes through the hollow shaft *T* directly into the air box, from there, on account of the presence of damper *C*, through the filters *F*, *F′*, and finally into the tuyeres, where its pressure (around 30 cm. mercury) is so regulated as to avoid an excess of oxidation of iron. This latter is kept particularly low, because of the tangential direction of the tuyeres combined with the truncated shape of the bottom which assures a gyratory movement to the bath of molten pig iron. The dimensions of the bottom of the converter have to be calculated in such a manner that the level of the pig-iron bath should be 5 to 6 cm. (2 to 2.4 in.) above the axis of the tuyeres when the apparatus is in a vertical position and the elimination of silica is going on right. This is essential in order to make certain the discharge of slags through the tap hole *S*.

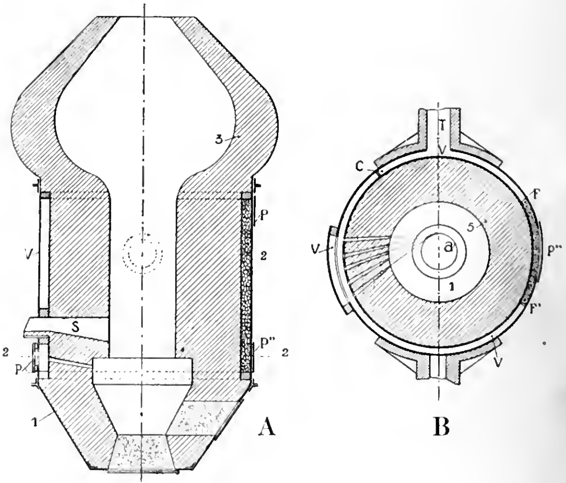

Fig. 2 Levoz Side-Blown Bessemer Converter

It is claimed that because of the lack of excessive oxidation of iron in decarburization goes on without excessive boiling and such material as may be thrown off by the bath is collected in the dome and returned to the bath again. Other advantages are claimed for this type of converter. (*La Fonderie Moderne*, no. 10, Oct., 1921, pp. 284–290, 3 figs., *dh*)

INTERNAL-COMBUSTION ENGINEERING (See also Aeronautics)

Tests of the 450-Horsepower Bristol Jupiter Engine. It is a remarkable fact that out of the three aeronautical engines which satisfied the rigid conditions laid down for the British Air Ministry test, one, the Bristol Jupiter, is of the air-cooled radial type. It is also lighter per horsepower than either of the two other makes which passed the test.

The present article, which is an abstract from the Report of the British Air Ministry, gives some data of these tests, which included a 50-hr. endurance test, slow-running test, high-speed test and high-power test. The average oil and gasoline consumptions throughout the tests were: oil, 0.094 pint per hp-hr; gasoline, 0.594 pint per hp-hr.; which are quite remarkable for an air-cooled engine.

On the full throttle test (with a special cam sleeve) the engine developed a maximum brake horsepower of 462 with a gasoline consumption of 0.566 pint per hp-hr.

One of the most interesting tests was the one-hour test with three cylinders cut out. The engine was set to run at 90 per cent

of normal full power, viz., 345 hp. at 1575 r.p.m. The gasoline from one carburetor was cut off, allowing the engine to run on six cylinders only. The engine was run one hour non-stop under these conditions. Naturally there was a certain amount of vibration, but it was not excessive.

At the end of the hour, gasoline was turned on, and the engine picked up to full load at once. The operation was generally satisfactory and there was no oiling up of plugs. The results obtained on six cylinders were as follows:

B.hp.	193
R.p.m.	1250
Oil consumption, pints per hp-hr.	0.0413
Gasoline consumption, pints per hp-hr.	0.685

The official weight of the engine complete but without exhaust pipes and intakes is 729.25 lb. (*Aviation and Aircraft Journal*, vol. 11, no. 24, Dec. 12, 1921, pp. 685–686, 2 figs., *e*)

Rotary-Valve Motor-Car Engine

Bournonville Rotary-Valve Engine. The valve consists of two hollow cylinders exactly alike and located end to end, which are driven at one-sixth crankshaft speed. It is located within the cylindrical casting which also forms the cylinder head but is referred to as a valve head. In this valve head the combustion chamber is formed in the casting in such a way that it can be easily machined. Mixture from the carburetor is delivered into the passage at the end of the valve and flows then through the passages of the two halves of the valve to both ends of the valve and then enters a passage called "inlet passage" cored in the valve head. This passage extends the whole length of the valve head and mixture can enter it from both ends. It is in communication successively with the different cylinder ports by pockets in the valve. Each half of the valve has three sets of three such pockets, each set being in line with the cylinder port of one cylinder, and the same pockets in the valve which serve for the inlet also serve for the exhaust.

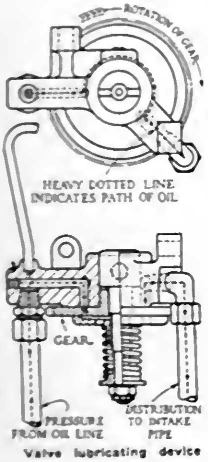

Fig. 3 Lubricating Device of the Bournonville Rotary Valve

The outstanding advantage claimed for the rotary valve is its absolutely silent operation; further, owing to the absence of top rods and valves at the side of the cylinder block, the accessories can be located close to the cylinders and the engine made quite narrow.

An interesting feature is the special feeding device by which one drop of oil is fed into the inlet pipe between the carburetor and valve head for every twelve revolutions of the crankshaft. This device, Fig. 3, is mounted on the gear case at the upper end of the vertical shaft on the forward end of the engine. It consists essentially of a spur gear which meshes with a spur pinion on the upper end of the vertical shaft. This spur gear is provided with an oil pocket which fills up with oil every time it comes into register with the oil inlet passage (communicating with the regular pressure lubricating system of the engine). After a motion of a little more than half a turn the pocket in the spur gear comes into register with the delivery port communicating with the charge inlet pipe, and the oil is then subject to the suction in the inlet port and is drawn into the charge stream therein, together with which it enters the inside of the rotary valve. Here the oil tends to separate out, owing to its greater inertia than that of the gaseous charge which asserts itself every time there is a change in the direction of motion, and to collect in eight internal circumferential oil grooves, four in each half of the valve. From these grooves radial holes are drilled to the outside of the valve. Through these holes the oil is gradually fed at several points to the bearing surface of the valve. (*Automotive Industries*, vol. 45, no. 22, Dec. 1, 1921, pp. 1065–66, 3 figs., *d*)

Two-Stroke Compound Engine

Silent Snow Two-Stroke-Cycle Engine. This engine, of unconventional design, is of the air-cooled type but has the mixture forced to the cylinders by a slow-speed pump. It is so arranged that a very large piston having a short stroke (31 mm.) pumps the charge into the combustion cylinder, in which is a working piston of the type ordinarily used in two-stroke-cycle engines. The inlet ports in the head of the cylinder are sealed by a speed ring somewhat like a very wide piston ring during the compression and working strokes, but are uncovered when the piston opens the exhaust ports by the fact that this ring contracts and thereby leaves its seat.

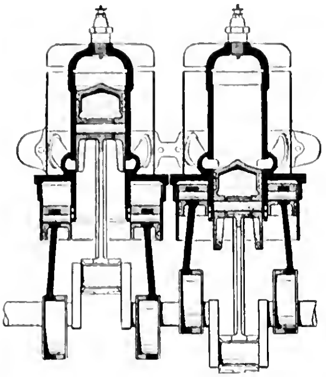

Fig. 4 Silent Snow Two-Stroke-Cycle Engine with Pumps Feeding Mixture to the Working Cylinders

The pump itself is concentric with the working cylinder. It lies within the crankcase. The pump piston is of very large diameter and annular shape so that the spigot of the working cylinder passes through the center, which necessitates an extra set of rings on the working-cylinder spigot.

The working piston is coupled to the crankpin by a connecting rod, while the pump piston is oscillated by eccentrics, straps and short connecting rods, the eccentrics being a part of the crankshaft (Fig. 4). The cycle of operations is as follows:

Immediately after the charge has been fired the working piston is driven down until the exhaust ports are uncovered. As soon as the pressure in the working cylinder falls as the gas is exhausted, the ring valve opens and at the same moment the pump piston forces mixture through the ports in the top of the cylinder, which gives good filling and scavenging. (*The Autocar*, vol. 49, no. 1362, pp. 1129–1130, 3 figs., *d*)

Superinduced-Engine Motor Car

Motor Car with Superinduced Engines, R. Krueger. It is claimed that speed-change gears not only constitute an expensive part of motor-car design but that their frequent use is both annoying and entails other disadvantages. Various methods are considered to eliminate them or reduce their use, the chief of which is the employment of the superinduction principle by equipping the motor with some kind of an air pump.

Among the apparatus described are the Roots (British) and Daimler (German) cars.

The Daimler apparatus is shown in Fig. 5. The motor *a* drives through a coupling *b* and a speed-change box *c*, which has, however, only very few speeds. The flywheel of the motor is surrounded by housing *d* and acts as an air compressor, the housing *d* being connected through pipe *f* with the carburetor *g* of the motor. The pipe *f* is provided with valve for cutting in and out the air precompressor.

The car may be operated with the aid of the speed-change drive with the precompressor *d* cut out, in which case the carburetor gets its air from the free atmosphere; or the precompressor may be cut in, in which case a further regulation may be obtained by

varying the pressure of the air supplied from the housing *d* to the carburetor *g*.

Furthermore, the speed-change-gear variations may be combined with the operation of the motor on precompressed air, all of this permitting a wide range of conditions of motor operation and power output. (*Der Motorwagen*, vol. 24, no. 30, Oct. 31, 1921, pp. 663–665, 4 figs., *d*)

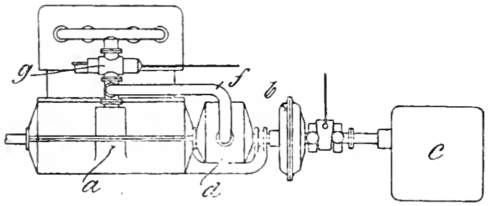

Fig. 5 Daimler Automobile Motor with Superinduction

MACHINE DESIGN (See also Mechanics)

Double Helical or Herringbone Gears, Howard H. Talbot. Discussion of the elements of design, such as tooth strength, friction of tooth surfaces, changes with degrees in spiral angle, tooth pressures, etc. The question of the use of long addenda in the pinion and short addenda in the driving gear to increase the "follow through" is discussed in particular.

As regards the tooth strength, it is recommended as safe to consider a helical tooth approximately one and a half times as strong as a spur tooth of the same tooth section.

The article is not generally suitable for abstracting, notwithstanding its interest.

The general conclusion to which the author arrives is that it is impractical to attempt any standard design of herringbone gears giving interchangeability as we have in the involute spur-gear system. (*The Iron Age*, vol. 108, no. 23 and 24, Dec. 8 and 15, 1921, pp. 1469–1473 and 1531–1533, 17 figs., *tpA*)

Simplified Approximations of Critical Speeds, G. Arrowsmith. This article shows a simple approximate method which may be applied to most cases which occur in practice without having to construct bending-moment and deflection diagrams. In the calculation of critical speeds of shafts extreme accuracy is not necessary, as experience has shown that for satisfactory running it is advisable to adopt a rotor of such proportions that the critical speed is removed by from 25 per cent to 35 per cent from the running speed.

Furthermore, a large proportion of cases which occur in practice deals with shafts freely supported at the ends. In such cases the error involved in accepting as a basis of calculation statical deflection as compared with the deflection due to the centrifugal loading is no greater than the error which may occur because of variations in the elastic modulus E of the shaft material.

The writer divides all rotors into two broad classes:

Where the shaft is comparatively flexible throughout its span (class A). For those cases where the ratio d/D (in a stepped shaft, ratio of diameter of smaller section to diameter of large section) is not less than 0.6, the critical speeds can be calculated in terms of weight, diameter, and length of span of shaft from

$$R_k = \frac{K \times 10^6 D^2}{\sqrt{W L^3}}$$

where R_k is critical speed; K is a constant the value of which varies from 1.57 for a centrally loaded shaft to 2.23 for uniform distribution of load; D is the diameter of shaft in inches; W the total weight of shaft between points of support in pounds, and L length of shaft between points of support in inches.

For values of d/D of less than 0.6 the shaft becomes more or less of class B, where the center of portion of shaft is of such dimensions as to render it practically inflexible as compared with the end portion of the shaft. In that case other equations given in the original article can be used, for example, equation $R_k = 187/\sqrt{Y_a + Y_b}$. Where Y_a is the static deflection of the shaft in inches and Y_b the extra deflection due to the flexure of the center portion.

Where d/D is considerably less than 0.6 the flexure of the center portion of shaft is negligible and simplified equations given in the original article may be used.

Illustrations of the applications of the process are given in the original article. (*Engineering*, vol. 112, no. 2917, Nov. 25, 1921, pp. 717–720, 8 figs., *mp*)

Steel Belts

Steel Bands for Power-Transmitting and Conveying Purposes, Bernard Kruger. In competition with ropes, leather and textile belts, metal bands have made great headway during the past few years in Europe, where it is stated that over 1000 steel-band conveyors are used and close to 1,000,000 hp. is being transmitted by steel bands.

The fundamental rule in the design of these bands or belts is based on the researches of Woehler, who found that a tension constantly varying from zero value to a maximum and frequently applied to a body will cause its destruction, provided the maximum tension is more than half the breaking stress of the material. With this in mind it is always possible to design a belt that will stand up at given stresses by giving it proper dimensions. The belts are made from carefully hardened and tempered carbon steel, rough rolled at red heat and then brought down to standard thickness and width by cold working.

The tensile strength of the finished material is about 95 tons per sq. in. The edges are rounded and so finished that the bands can be safely handled even when running at high velocity. Table 1 gives the approximate weights of belts of various kinds.

TABLE 1 APPROXIMATE WEIGHTS AND DRIVING WIDTHS OF LEATHER BELT, COTTON ROPES, POWER CHAIN, AND STEEL BAND FOR TRANSMITTING 200 HP. AT ABOUT 3000 FT. PER MIN.

System	Weight per foot, lb.	Driving width, in.
Double leather belt	6	24
Five 2-in. ropes	7	15
Three-inch pitch chain	43	7
Steel band	15	8

Owing to the high modulus of elasticity of steel it is very necessary to determine the length of a driving band with considerable accuracy, for a slight extension made necessary by cutting the band too short in the first instance will set up very serious stresses. An ingenious device has accordingly been invented for determining the exact length necessary to obtain a truly correct working tension, allowance being made for the sagging of the band. In this device a measuring band of small breadth and of definite section is mounted on to the pulleys on which the operating band will subsequently be required to run, and the ends fitted into a tension frame. By means of a helical spring and calibrated nut, by the compression of which the arms of the tension frame approach one another, the total tension equaling the desired initial stress per square millimeter in the driving band is read off on a scale provided for the purpose. One of the pulleys around which the band is placed (or also both pulleys in opposite directions) is now slowly rotated so that the friction of the pulley causes a rise in tension in that branch of the band in which the tension apparatus is placed, without, however, the band being driven by the pulley. The tension indicated by the apparatus is noted, the pulley or pulleys are then rotated in the reverse direction, so that the branch under test is slackened to a certain extent; the tension then indicated by the apparatus is again read, and it is ascertained whether the arithmetical mean of the two tensions which has been read corresponds to the desired fundamental tension. The overlaps of the ends of the measuring band are now cut off, and, the tension being released, the remaining length is the correct measurement to which the driving band unstrained must be cut.

In order that metal shall not run to metal and to prevent any possible slip, a friction coating consisting of a layer of canvas, to which are glued thin sheets of cork, is placed over the pulley rim, and to avoid stripping under variable load the pulley rim is first serrated by means of a rough file. A special cement is available for use in very damp situations

In steel-band transmission it is necessary that the pulley face shall be flat; this is owing to the fact that if the pulley is crowned the centers of gravity of the joint clip will be raised slightly from the pulley every time the clip runs on to the latter, thus causing

a blow to be struck which is greater the smaller the pulley diameter and the higher the belt speed. The stress caused by such a blow will be thrown mainly on to the middle of the band and this will cause gradual deterioration of the material at this point and ultimate fracture. As power for power the steel band is only one-third the width of an equivalent leather belt, the use of specially narrow and correspondingly stronger pulleys enables considerable saving in weight to be made, particularly in large diameters, at the same time considerably reducing the cost.

Assuming from a millwright's point of view that the shafts and bearings are properly proportioned and fixed and that the amount of power to be transmitted has already been determined, the necessary calculations are then made for the size and length of the belt to be used. These are based upon carefully worked-out formulas, and as the material is practically static (the maximum and minimum contraction and expansion being only $^1/_{32}$ in. to the yard), the tension necessary for any particular power or width is exactly determined. Thus it will be readily understood that when once the belt has been mounted in the manner previously described it requires no further adjustment.

In many cases, particularly for short conveyors and for certain classes of material, the upper strand of the steel band can slide on a timber support instead of being carried on rollers.

The only variations in length of the band to be taken into consideration are those due to changes in temperature. For short conveyors the tension of the band is adjusted by means of movable bearings of the driven terminal pulley. For conveyors 130 ft. or more in length as well as for conveyors handling warm material, the driven terminal pulley is fitted on a tension frame supplied with counterweights or steel springs to obtain the necessary stretching force.

Various other practical points are discussed, among them applications of the conveyor with steel bands not hitherto considered possible. (*Journal of the Western Society of Engineers*, vol. 26, no. 12, Dec. 1921, pp. 428–432. In this connection attention is called to the paper and experimental investigation of steel belting by F. G. Hampton, C. F. Leh and W. E. Helmick, MECHANICAL ENGINEERING, vol. 42, no. 7, July, 1920, pp. 369–378, 13 figs., to which a short bibliography on the subject is appended)

MACHINE SHOP (See Engineering Materials)

MECHANICS

Simplified Calculation of Rigid Frames

A NEW PROCESS DEVISED BY H. BRONNECK FOR CALCULATING RIGID FRAMES, Professor Marx. An abstract of a chapter from a book by H. Bronneck which has just been published in Berlin, the interest of which lies in the fact that a method is provided for computing the most complicated frame shapes directly and without the use of tables.

Bronneck starts from the fundamental equations laid down in the works of Mueller-Breslau and Moersch. The case of a simple rectangular double-articulated frame may be used to illustrate the process. For this case the shear may be computed from the following equation:

$$x = \frac{\frac{J_c}{J_0}\int_0^h M_0\, y\, dy + \frac{J_c}{J_1}.\, h\int_0^l M_1.\, dx + \frac{J_c}{J_0}\int_0^h M_2\, y\, dy}{\frac{J_c}{J_0}.\,\frac{2}{3}h^2 + \frac{J_c}{J_1}.\, l.\, h^2\frac{J_c}{F_1}.\, l}$$

Here M_0, M_1 and M_2 are the bending moments at points 0, 1 and 2 (Fig. 6) induced by external load with the frame statically determined in some manner: J_0 and J_1 are respectively the moments of inertia of the rods and traverses, while J_c is any moment of inertia whatsoever. If, now, to every part dy of the rods be added elastic weight $\frac{J_c}{J_0}.\, dy$, the first two members in the numerator of the above equation become nothing else but the moments of inertia of the entire frame refer to axis A-B denoted henceforth as T_a. The member $\frac{J_c}{F_1}.\, l$ is produced by the action of the longitudinal forces

The expression $\frac{J_c}{J_0}\int_0^h M_0.\, y.\, dy = \int_0^h M_0\left(\frac{J_c}{J_0}.\, dy\right)y$ represents the static moment of the surface of moments located over the rod AC referring to the AB and hence

$$\int_0^h M_0\left(\frac{J_c}{J_0}.\, dy\right).\, y = \left(\frac{J_c}{J_0}.\, f_0\right).\, y_{so}$$

Here f_o is the area of the surface of moments and y_{so} the distance of the center of gravity of the surface from AB. The two other expressions in the numerator of X may be determined in a similar manner. If, now, we denote the sum of all these expressions by S_a we obtain for the shear on the frame the very simple expression:

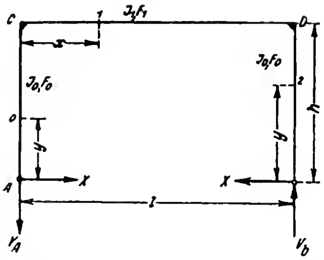

FIG. 6 DIAGRAM OF FORCES ACTING ON A DOUBLE-ARTICULATED FRAME

$$X = \frac{S_a}{T_a\,\frac{T_c}{F_a}.\, l}$$

By means of this formula the shear may be computed for all possible cases of loading, and the influence of heat variations can be very well taken into consideration in this formula which applies to all cases of double-articulated frames, no matter what their shape may be.

From this Bronneck proceeds to the determination of an equation for the influence lines for S_a for various frame shapes and types of loading.

Such equations for the influence lines can be derived now by means individual for each frame shape. Bronneck has, however, succeeded in deriving an equation of the third degree for computing this statically undetermined magnitude, this equation being $y = a + bx + cx^2 + dx^3$. Here a, b, c and d are constants which depend only on the shape and dimensions of the frame, while x is the variable distance of the single load (1) from a predetermined origin of coördinates. The equation permits, therefore, of immediate numerical computation. (*Dinglers Polytechnisches Journal*, vol. 336, no. 21, Oct. 22, 1921, pp. 301–302, 2 figs. *mA*)

THE EXPONENTIAL METHOD IN THE ANALYSIS OF THE BALANCE OF RECIPROCATING MASSES, P. Cormack. (A mathematical article not suitable for abstracting.) A method is developed from the usual formula for inertia resistance of a reciprocating piston mass expressed by a rapidly convergent series. The author converts this series into an exponential series which is made the basis for his calculation. This calculation is applied to such cases as that of seven-crank engines, offset cylinder engines, radial engines and rotating-cylinder engines; and, among other things, shows that the angular accelerations of the connecting rods are identical in the radial and rotary types. (*Engineering*, vol. 112, no. 2919, Dec. 9, 1921, pp. 778–780, 1 fig., *m*)

MARINE ENGINEERING (See Steam Engineering)

MOTOR-CAR ENGINEERING (See also Internal-Combustion Engineering)

Maybach Powerplus-Cylinder Gearless Car. During the war aeroplane engines were developed working on the so-called "powerplus" idea, that is, the cylinders were made considerably larger than corresponded to the dimensions of the driving parts. The powerplus-cylinder aeroplane engine was intended to work at part throttle on the ground and at full throttle at high elevations, thus developing practically the same power at varying altitudes. The same principle with slight changes has been applied in the new Maybach engine. This engine is fitted with six cylinders 95 mm. (3.75 in.) in diameter by 135 mm. (5.32 in.) stroke. At 900 revolutions it develops 36 hp. and at 2200 revolutions, that is, with full throttle open, 72 hp., this power output being so great as to make speed-change gear unnecessary, except on unusually heavy grades. For use on exceptionally heavy inclines a reducing gear is connected between the engine and the driving shaft. The drive backward is achieved by means of an electric starter, no reversing gear being used.

In this connection the statement is made that the Daimler Motor Co. has provided an arrangement for temporarily increasing the torque by 50 to 100 per cent in their new car. Steel-cylinder engines are used and the device presumably consists in an arrangement for increasing the pressure of the charge drawn into the cylinder, but nothing has been divulged as to its details. (*Engineering Progress*, vol. 7, no. 11, Nov., 1921, pp. 242–243, 1 fig., *d*.—The abstract refers to part of an article entitled The German Automobile Exhibition 1921, pp. 241–246, 9 figs.)

POWER-PLANT ENGINEERING (See also Steam Engineering)

Temperatures and Gas Velocities in Boiler Settings, A. W. Binns and C. E. Joos. Results of tests on a 1000-hp. Stirling boiler with a temperature chart taken by a recording Brown pyrometer. The results are given in tables and curves. (*Power Plant Engineering*, vol. 25, no. 23, Dec. 1, 1921, pp. 1138–1139, 3 figs., *l*)

South Meadow Plant of the Hartford, (Conn.) Electric Light Company. The plant is laid out so as to give an ultimate capacity of 130,000 kw. in five units, with enough ground available to extend this rating to 260,000 kw. The design of the plant is such as to make it readily adaptable to superpower service and has been controlled by the idea of providing twofold service—local and regional.

One of the many interesting features of the plant is the provision of a room for auxiliary and combustion-control equipment, with indicating and recording instruments for measuring pressures, temperatures, steam flow, gas analysis and power output. By this arrangement one man is in a position to maintain proper conditions throughout the plant at all times.

Several other features such as methods of fuel handling, boiler rooms, and the somewhat unusual system of piping, are described in the original article. (*Electrical World*, vol. 78, no. 24, Dec. 10, 1921, pp. 1163–1166, *d*)

RAILROAD ENGINEERING

The "Meteor" Track Torpedo. A new type of track torpedo officially adopted on all lines of the Canadian Pacific Railway. It appeals to all three senses, namely, hearing, seeing and smelling, and on detonation produces not only a loud report but simultaneously a brilliant flash and pungent smell. It is called "meteor" and is fastened to the tracks by means of two spring rail clips made of tempered steel or spring brass. In this way a firm gripping of the rail head is assured and at the same time a prompt application of the torpedo is made possible.

It is completely waterproof, will stand any atmospheric conditions of heat, moisture and frost. It has been subjected to one hundred hours' immersion, and one hour in moist steam at 120 deg. fahr., without deterioration, and has been used where the temperature was many degrees below zero with complete success. Special tests have been carried out to ascertain its holding power when placed in position on the rail, and for flying particles likely to cause injury to bystanders. These have all been carried out with satisfactory results. (*Canadian Machinery*, vol. 26, no. 22, Dec. 1, 1921, p. 51, *d*)

SPECIAL PROCESSES

Rotary-Type Gas Filter

Rotary Filter Process of Cleaning Gases and Vapors. A description of a process intended to be used for removing dust, tar, oil and similar impurities from gases and vapors developed by Freytag-Metzler and tested by E. Stach and Doctor Alexi. The principle of this device is illustrated in Fig. 7 and is based on a continuous renewal of the filter material placed in a slowly rotating filter casing surrounding coaxially a high-speed fan wheel. The filter casing consists of a wrought-iron hollow ring of rectangular cross-section divided into several chambers by intervening walls and rolling on bearings in the lateral covers of the general housing. Between the fan wheel and the filter casing there is a clearance of predetermined width. The material used for filling the filter chambers depends on the impurities that have to be handled.

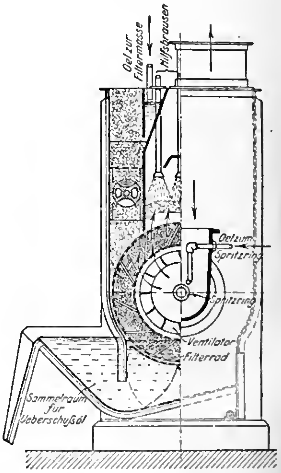

Fig. 7 Freytag-Metzler Gas Filter

(*Oel zur Filtermasse* = oil flow to filter mass; *Hilfsbrausen* = Auxiliary sprinkler; *Oel zum Spritzring* = oil flow to spray ring; *Spritzring* = apray ring; *Ventilator* = fan; *Filterrad* = filter wheel; *Sammelraum fuer Ueberschussoel* = sump for oil overflow)

Thus, for example, for cleaning gases from blast furnaces, copper, zinc and tin smelting furnaces and ceramic kilns, water is used as the cooling and washing liquid, while the filter body is made up of metal, fiber and steel shavings. A small amount of water is sprayed into the fan wheel, while a generous spray is provided from on top. The atomization of water in the fan wheel and its mixing with the gas assists the filter action materially. In order to prevent the filter mass from getting stuffed up by the clinkering of the impurities, which is particularly likely to happen with blast-furnace and cement-kiln gas, the ring constituting the filter housing is placed well away from the fan wheel and the water spray comes between the filter proper and the fan wheel.

The rotary filter can be used for taking oil out of steam and also has an absorption device. (*Zeitschrift des Vereines deutscher Ingenieure*, vol. 65, no. 49, Dec. 3, 1921, pp. 1265–1267, 7 figs., *d*)

STEAM ENGINEERING

Low-Pressure-Turbine Blade Failures in Destroyers, Lt-Com. D. F. Ducey, U. S. N. The investigation was undertaken to determine the causes of certain failures of low-pressure-turbine blading which occurred in the late summer of 1919 on vessels built during the war. From this investigation the following facts were established: Seventeen of the failures occurred in the port low-pressure turbines and five in the starboard low-pressure turbines. The reason for the greater number of failures in the port turbine has not been established and is a subject for further investigation. A theory involving vibration and the greater length of the port lineshafting has been advanced, but this can remain an open problem for the present.

The primary failure, as far as could be ascertained, involved but one or two blades in a single stage. In instances from one to fifteen blades in a single stage were found stripped, but indications were that the failing of one or two blades was the cause of the others going. In no case was there any indication of a general failing of

the blades, the damage usually being confined to the blades being held by a single section of shrouding.

Practically all of the blades ruptured across the root section, although in certain instances where there was a tearing action by the shroud band and loose blades, the rupture occurred higher up on the blade.

In only one instance, that of the 280, did serious vibration exist previous to the blades failing.

Sometimes, when the failure occurred in the earlier stages, the ruptured blade or blades, in going through the following stages, tore blades out of these stages; in other instances the ruptured blade or blades went through as many as three stages and the intervening diaphragm nozzles, without tearing loose other blades. It would be expected that in such cases one would find the blades in the stages intervening between the stripped section and exhaust space badly chewed up, but such was not always the case. The "chewing-up" was usually of minor importance and in one case but five or six blades per stage were involved. As a rule the diaphragm nozzles were easily straightened and but one case of extensive renewals being necessary can be recalled. Incidentally this speaks well for the ruggedness of the turbine design.

Certain imperfections of manufacturing have been discovered, but neither defective material nor excessively bad workmanship has been found to be present.

The material was tested in various ways and chemical analyses and a metallurgical investigation made.

The tests have served to give evidence of the possibility of inducting brittleness in the chrome-nickel steel used for the blading. Furthermore, the design of the type of turbine blade used is such that a sudden change of section occurs between the root and the blade body. This section is the one of maximum bending moment and the maximum stress under bending would be considerably greater even than the theoretical stress. In tests, some of the specimens broke badly or showed cracks.

The general conclusion arrived at, therefore, is that the cause of trouble lay largely in the design of the turbine blade, which was such as to be very poorly fitted for undergoing plastic deformation when bent, without the formation of cracks at the junction of root and blade. This is particularly so, as in some cases there was a tendency to brittleness in the material due to improper microstructure or other causes.

A number of practical recommendations are made. (*Journal of the American Society of Naval Engineers*, vol. 33, no. 3, Aug., 1921, pp. 512-540, numerous illustrations, *deA*)

TESTING AND MEASUREMENTS (See Engineering Materials)

TRANSPORTATION

System of Handling L. C. L. Freight in St. Louis, Mo. In St. Louis the Columbia Terminals Co. handles practically all of the less-than-carload freight lots interchanged between the western lines terminating in St. Louis and the eastern lines with depots in East St. Louis, Ill., across the Mississippi River. It also carries to its own warehouses on either side of the river shipments that arrive over different lines for St. Louis or East St. Louis points. From there the consignee can gather in at the same time all of the articles that may have been shipped from a dozen different points and over a dozen different railroads.

The Columbia Terminals Co. which does this work is paid not by the shipper or consignee but by the railroads themselves, who, by the way, make no additional charge for this service. They are enabled to do this because of the fact that it costs them less to handle this kind of freight by truck than by rail. The Columbia Terminals Co. handles only L. C. L. freight, the transfer of carload shipments from eastern to western lines and for local deliveries being in the hands of the Terminal Railroad Association. All the work of hauling is done by 170 horse-drawn vehicles, 75 motor trucks and 35 tractors drawing 150 Lapeer steam trailers.

It is claimed that through its use of trucks and trailers the company handles freight in from 24 to 72 hours less time than it takes to do so in most of the other great gateways of the United States.

The company has a tariff on the same principle as the railroads but no contract with the roads. (*The Commercial Vehicle*, vol. 25, no. 10, Dec. 15, 1921, p. 7-11, 9 figs., *dA*)

VARIA

The Open Price Association Decision of the U. S. Supreme Court. The American Hardwood Manufacturers Association for some time has maintained a statistical service to its members by which they have been informed of prices at which sales were closed and of impending changes in prices. The U. S. Supreme Court has declared this practice illegal and the dicision has already attracted considerable attention in trade circles. The *Iron Age* (vol. 108 no. 25, Dec. 22, 1921, pp. 1612-1613), believes that this decision will have far reaching effects on all business organizations which seek directly or indirectly to stabilize prices. On the other hand, however, it considers it improbable that the decision will render it impossible for industrial groups to study their respective economic problems.

The *Engineering News-Record* goes into the subject far more extensively but does not believe that the decision in the Hardwood Manufacturers' case finally determines the scope of activities of open-price associations. It considers it final only as to one activity viz., advising on future action.

From the decision in this case it does not appear that mere exchange of information regarding production, stocks and shipments, as well as prices on closed transactions is illegal; support for this opinion is found in the decision of the U. S. District Court of the Northern District of Illinois in the case of the linseed-oil crushers. The Hardwood Manufacturers, however, have gone a step too far.

Passing, however, from the consideration of purely legal aspects of the case, the *Engineering News-Record* expresses the belief that while exchange of information upon closed transactions confined strictly to the membership of an association may be lawful, it is not good policy, as the public, kept in ignorance of these practices but keenly realizing the power that such an exchange gives trade associations, becomes suspicious. The only way to establish confidence in such exchange of information is to follow the practices of stock exchanges and make this information available not only to the sellers, but also to the buyers.

As an instance of the displeasure caused by lack of frankness in giving out price information, the *Engineering News-Record* cites the cement industry. Notwithstanding the many efforts of that journal to obtain from the cement associations statistics on production (not prices), this could not be brought about. The feeling among consumers of cement is so strong in this regard that an influential group of consumers discussed means by which an open cement exchange could be established, in the direction in which public pleasure may be asserted in industries which are mistrusted. (*Engineering News-Record*, vol. 87, no. 26, December 29, 1921, pp. 1046-1047)

CLASSIFICATION OF ARTICLES

Articles appearing in the Survey are classified as *c* comparative; *d* descriptive; *e* experimental; *g* general; *h* historical; *m* mathematical; *p* practical; *s* statistical; *t* theoretical. Articles of especial merit are rated *A* by the reviewer. Opinions expressed are those of the reviewer, not of the Society.

The report (Great Britain) made by Lord Newton's Committee on Smoke and Noxious Vapor Abatement emphasizes the fact that smoke pollution is mainly due to the indiscriminate and wasteful use of raw coal for all purposes, and that this pollution can only be overcome by the government and municipalities taking joint legislative action. Among the recommendations of the Committee is one to the effect that the Ministry of Health should be given power to deal with local authorities who fail to administer the law with regard to smoke emission.

The situation with respect to the domestic fuel problem is recognized and control recommended over the heating arrangements in such new buildings as hotels, clubs, and offices. (*Cp. The Electrician*, vol. 87, no. 2276, Dec. 30, 1921, pp. 806-807.)

ENGINEERING RESEARCH

A Department Conducted by the Research Committee of the A.S.M.E.

Gases in Metals

A WIDE field for research of great practical value is the acquiring of exact knowledge of the gas content of metals. Aside from the more or less familiar relation of gases to the deoxidation of steel and the production of sound ingots and castings, many operations in the refining, working, and treating of metals are vitally effected by the presence of various gases.

Many of the inherent differences in quality of steels made by different processes are generally attributed to the amounts and compositions of the gases with which the metal is in contact when in the molten state in a converter, open-hearth or electric furnace, or in a crucible. It is reported that steel converters operating in a vacuum have recently been successfully used on a commercial scale in England to produce cutlery steel of unusually fine quality. The presence and nature of occluded gas in cast iron has been said to be closely connected with two of its important characteristics, namely, the graphitization of cast iron and the growth of gray cast iron.

Of no less importance are dissolved or occluded gases in non-ferrous metals. For example, the fire refining of copper is wholly a matter of intentionally dissolving a gas (oxygen) in crude copper and then removing nearly but not quite all of this same gas. If the final step of this refining is carried only a minute or two longer than necessary resulting in the complete removal of oxygen, the whole furnace charge must be entirely reworked as if it were a fresh charge of crude copper.

In the working and fabrication of copper, gases also play a part. Operations involving the cleansing of steel or iron by pickling in acids must be followed by treatments designed to remove the hydrogen taken up from the metals by the gases. If not removed this occluded gas will render the metal too brittle to work or will give trouble in subsequent operations when the metal is exposed to heat, as, for instance, causing blisters in enamel. Occluded gases have also been shown to have a marked effect on the electrical conductivity of metals, their magnetic properties, their consistency in dimensions, as well as their mechanical properties.

Research Résumé of the Month

A—Research Results

The purpose of this section of Engineering Research is to give the origin of research information which has been completed, to give a resume of research results with formulas or curves where such may be readily given, and to report results of non-extensive researches which in the opinion of the investigators do not warrant a paper.

Automotive Vehicles and Equipment A1-22. METHOD OF MEASURING TEMPERATURE AT DIFFERENT POINTS IN THE BODY OF AN AUTOMOBILE TIRE. Mr. A. O. Ashman in a 14-page pamphlet describes a simple method of using thermocouples to explore the temperature conditions in rubber tires. A copper-constantan thermocouple is employed in conjunction with a potentiometer. Address the New Jersey Zinc Company, 160 Front St., New York.

Fire Prevention A1-22. "SHEETROCK." A series of exhaustive tests on this material which may be used for interior wall, ceiling and partition finish have been conducted by the Underwriters' Laboratories and are published by them in a 97-page pamphlet. "Sheetrock" is of the single-cored wall-board type and paper-covered fibered gypsum-plaster pattern. It consists of a layer of fibered hydrated gypsum reinforced by a sheet of heavy tough sized paper securely bonded to the surface on each side. The surfaces on both sides are smooth and true and light gray in color. Great strength combined with toughness as well as heat insulation and fire-resisting qualities are the principal claims for this building material. Address Underwriters' Laboratories, Chicago, Ill.

Fuels, Gas, Tar and Coke A4-22. COAL CARBONIZATION. Present Status of Coal Carbonization at Low Temperatures is the title of Report 2292 to the Bureau of Mines by Joseph D. Davis. The paper was read at the meeting of the American Gas Association on Nov. 9, 1921. The conclusions of the report which gives the meaning of low-temperature carbonization, amount and character of products, uses of products, suitable coals, principles, apparatus and processes are as follows:

"Although increased interest has been manifested in low-temperature carbonization during the past year, progress toward commercial development has been slow. This is probably due in part to market conditions and in part to difficulties experienced by builders in perfecting their apparatus mechanically.

"In order that a low-temperature industry may be firmly established, it is necessary that the popular prejudice against soft coke be overcome, and it will take time to accomplish this.

"It does not appear that low-temperature methods are destined soon to occupy an important place in the gas industry in so far as gas for city supply is concerned. They may, however, be used to advantage in the production of industrial gas.

Bureau of Mines, Washington, D. C. Address H. Foster Bain, Director.

Machine Design A1-22. BEARINGS IN BRONZE BUSHINGS. As a result of a research carried on by the Engineering Department of the American Bronze Corporation, data sheets have been developed which contain considerable information of value under the headings, Running Clearances, Permissible Angular Deflection for Journals in Plain Bearings, Relation of Rubbing Speed to R.P.M. Allowances for Press Fits, and A Meritorious Design of Water Pump for Automotive Engines. These data sheets are numbered 107, 108, 109, 110, 111 and 112. Address American Bronze Corporation, Berwyn, Pa.

Mechanics A1-22. FATIGUE OF METALS. The results of the past three years' investigations of Profs. H. F. Moore and J. B. Kommers on the Fatigue of Metals have just been published as Bulletin No. 124 of the Engineering Experiment Station of the University of Illinois. This bulletin consists of 185 pages and reports in full the method of procedure of experimenters, results obtained and the conclusions which they have drawn. A summary of their conclusions is as follows:

1 For the metals tested under reversed stress there was observed a well-defined critical stress at which the relation between unit stress and the number of reversals necessary to cause failure changed markedly. Below this critical stress the metals withstood 100,000,000 reversals of stress, and, so far as can be predicted from test results, would have withstood an indefinite number of reversals. The name endurance limit has been given to this critical stress.

2 In the reconnaissance tests made in the field of ferrrous metals no simple relation was found between the endurance limit and the "elastic limit," however determined. The ultimate tensile strength seemed to be a better index of the endurance limit under reversed stress than was the elastic limit. The Brinell hardness test seemed to furnish a still better index of the endurance limit. The reason why the Brinell test, and, to a less degree, the ultimate tensile strength, seem to be better indices of the endurance limit than the elastic limit is not clear, and this result should be regarded as tentative. Elastic limits determined from compression tests and torsion tests gave no better index than did those from tension tests.

3 The single-blow impact tests (Charpy tests) and the repeated-impact tests did not furnish a reliable index for the endurance limit under reversed stress of the ferrous metals tested.

4 Accelerated or short-time tests of metals under repeated stress, using high stresses and consequent small numbers of repetitions to cause failure, are not reliable as indices of the ability of metal to withstand millions of repetitions of low stress.

5 The endurance limit for the ferrous metals tested could be predicted with a good degree of accuracy by the measurement of rise of temperature under reversed stress applied for a few minutes. This relation is explicable in view of the intercrystalline and intracrystalline slippage under repeated stress shown by the microscope. It is believed that this test, which is a development of a test proposed by Mr. C. E. Stromeyer, can be developed into a reliable commercial test of ferrous metals under repeated stress. Its applicability to non-ferrous metals has not been investigated.

6 Abrupt changes of outline of specimens subjected to repeated stress greatly lowered their resistance. Cracks, nicks, and grooves caused in machine parts by wear, by accidental blows, by accidental heavy overload, or by improper heat treatment may cause such abrupt change of outline. Shoulders with short-radius fillets are a marked source of weakness.

7 Poor surface finish on specimens subjected to reversed stress was found to be a source of weakness. This weakness may be explained by the formation of cracks due to localized stress at the bottom of scratches or tool marks.

8 Stress above the endurance limits, due to either a heavy overload applied a few times or a light overload applied some thousands of times, was found to reduce somewhat the endurance limit of two ferrous metals tested.

9 In none of the ferrous metals tested did the endurance limit under completely reversed stress fall below 36 per cent of the ultimate tensile

strength, for only one metal did it fall 40 per cent, while for several metals it was more than 50 per cent. However, these metals were to a high degree free from inclusions or other internal defects; the specimens had no abrupt changes of outline, and had a good surface finish.

10 It is well known that subjecting steel to a stress beyond the yield point raises the static elastic tensile strength to a marked degree. The effect is less marked on the endurance limit, although some increase was observed for 0.18 carbon steel with the surface polished after being stretched well beyond the yield point. Annealing of commercial cold-drawn screw stock was found to lower its endurance limit somewhat less than it did its static strength.

11 The test results herein reported indicate the effectiveness of proper heat treatment in raising the endurance limit of the ferrous metals tested. Here again it should be noted that an increase in static elastic strength due to heat treatment is not a reliable index of increase of endurance limit under reversed stress.

12 The phenomenon known as "fatigue" of metals under repeated stress might better be called the "progressive failure" of metals. The most probable explanation seems to be that such failure is a progressive spread of microscopic fractures. A nucleus for damage may be a very small area of high, localized stress, due to a groove, a scratch, or a crack; in other cases failure may be due to internal inclusions or irregularities of structure; it may be due to internal stress remaining after heat treatment; it may be due to a grain or group of grains unfavorably placed to resist stress; or failure may begin in the weaker grains of a metal whose structure consists of two or more kinds of grains; or it may, or course, begin in any portion of the metal which, by accidental overload or otherwise, is stressed to the yield point. Address Engineering Experiment Station, The University of Illinois, Urbana, Ill.

Metallurgy and Metallography A1-22. ZIRCONIUM. Bulletin 186 of the Bureau of Mines gives reports of investigations on zirconium with reference to the metal and oxide by J. W. Marden and M. N. Rich with historical review and bibliography. The Bulletin covers 152 pages and contains numerous drawings and tables. Bureau of Mines, Washington, D. C. Address H. Foster Bain, Director.

Paints, Varnishes and Resins A1-22. WATER-RESISTING SPAR VARNISH. Circular 103 of the Bureau of Standards is devoted to specifications for water-resisting spar varnish. These specifications were prepared under the auspices of the Bureau of Standards by the U. S. Interdepartmental Committee on Paint Specification Standardization, which consists of representatives of all the Governmental Departments, the U. S. Shipping Board, and the Educational Bureau of the Paint Manufacturers' Association of the United States. The specification gives the general requirements and detailed methods of sampling and testing as well as the basis for purchase. Address Superintendent of Documents, Washington, D. C.

Paints, Varnishes and Resins A2-22. INTERIOR VARNISH. The Bureau of Standards has recently prepared Circular No. 117 which consists of specifications for interior varnish. This specification was prepared by the same Committee mentioned above and gives the general requirements and detailed methods for sampling and testing of interior varnish as a basis for purchase. Address Superintendent of Documents, Washington, D. C.

Photography A1-22. BATHS FOR COLOR SENSITIVE PHOTOGRAPHIC PLATES. An interesting paper on color sensitive plates and methods of sensitizing by bathing has been prepared by the Bureau of Standards and issued as Scientific Paper No. 422. Directions are given for sensitizing plates and film, and the relative advantages of various sensitizers are considered. The various brands of orthochromatic plates which are found to be especially satisfactory, are mentioned, and it is noted that washing commercial panchromatic plates had a favorable action on the color sensitiveness. Address Bureau of Standards, Washington, D. C., S. W. Stratton, Director.

Properties of Engineering Materials A7-21. WASTE SLATE AS FILLER. Report 2283 of the Bureau of Mines discusses the use of waste slate as a filler for various materials. Report 2230 discussed the use of slate dust in asphalt road mixtures. The present report discusses the use as a filler for mechanical rubber goods such as disks, sheet packings, molded heels and soles, hard-rubber battery jars, carriage tires, garden hose, clutch facings and similar products. Slate flour was used successfully as a substitute for whiting, clay, barytes and aluminum flakes. With this filler the rubber would not stand repeated stretchings so readily. It has been found that it may be used as a filler for oilcloth, floor coverings and window-shade materials. It has been used as filler for plaster roofing and flooring. Bureau of Mines, Washington, D. C. Address H. Foster Bain, Director.

Protective Devices and Methods A1-22. GAS MASKS FOR GASES MET IN FIGHTING FIRES. As a result of the war the gas mask, which uses a chemical filter for removing poisonous gases and fumes from air, has been developed to a high state of perfection. The mask used by the United States Army is capable of giving complete protection against all the deadly gases that have been met on the battle field, but it does not protect against all the gases or atmosphere encountered in mines and in the industries and in fire fighting. A very thorough study of the construction of the various types of gas masks for use in fighting fires has been made by Arno C. Fieldner, Sidney H. Katz and Selwyne P. Kinney. The results of their investigation are recorded in Technical Paper 248 of the Bureau of Mines. Address Bureau of Mines, Washington, H. Foster Bain, Director.

B—RESEARCH IN PROGRESS

The purpose of this section of Engineering Research is to bring together those who are working on the same problem for cooperation or conference, to prevent unnecessary duplication of work and to inform the profession of the investigators who are engaged upon research problems. The addresses of these investigators are given for the purpose of correspondence.

Foundry Equipment, Materials and Methods B1-22. MOLDING SAND. Hundreds of thousands of tons of molding and core sands are used annually in the iron, steel and non-ferrous foundries of America. A little of it is re-used; much more might be. Sands are not always correctly selected for specific purposes. Mixing and other treatment can secure improvement. In what ways can foundry practise as to sands be bettered? What economies can be realized, not only in reduced expenditure for sand, but also in less number of lost castings and higher quality of accepted product?

Last spring, the American Foundrymen's Association decided that thorough study of this subject would be profitable and asked the coöperation of the American Institute of Mining and Metallurgical Engineers. The Institute referred this request to the Division of Engineering of the National Research Council, of which it is a member. Through joint action with the division a valuable digest of the literature has been made by Professor Robert E. Kennedy, of the University of Illinois, and a large committee of foundrymen, engineers and scientific men has been selected, under the general direction of President W. R. Bean, of the Foundrymen's Association and the chairman of the division.

This committee on molding sand research has just been organized with the following officers and executive committee:

Chairman: R. A. Bull, consulting engineer, Sewickley, Pa.
Secretary: Robert E. Kennedy, assistant secretary of the American Foundrymen's Association, Urbana, Illinois.
W. R. Bean, president of the American Foundrymen's Association, Naugatuck, Conn.
Henry B. Hanley, metallurgist and chemist, New London, Conn.
Jesse L. Jones, metallurgist of the Westinghouse Electric and Manufacturing Co., E. Pittsburgh, Pa.
Prof. Henry Ries, Department of Geology, Cornell University, Ithaca, New York.
Dr. Bradley Stoughton, consulting engineer, New York City.
Dr. George K. Burgess, chief of the Division of Metallurgy, Bureau of Standards, Washington, D. C.

The committee has thirty-five members, representing the many interests in the use of molding sand.

At a meeting of the executive committee on November 26, in the office of Division of Engineering, Engineering Societies Building, New York City, three subcommittees were appointed to deal (1) with the formulation of standard tests for determining the working properties of molding sand, (2) reclamation of molding sands and greater use of old sands and (3) methods of manufacturing synthetic sands. A meeting of the main committee in the Engineering Societies Building, New York, was planned for December 9, to lay out a comprehensive program of research which will include the assigning of the various problems to appropriate laboratories and industrial plants. Some field work will be necessary in connection with these investigations.

The coöperation of men having like interests in Canada and England is assured and invitations have been extended to France and Belgium. Address Alfred D. Flinn, Chairman of Division of Engineering, National Research Council, 29 West 39th Street, New York.

Foundry Equipment, Materials and Methods B2-22. ELIMINATION OF OXIDIZIBLE ELEMENTS IN CAST IRON. John H. Moffett, formerly metallurgical engineer at the University of Cincinnati, is now in charge of the foundry practice in the Department of Mechanical Engineering at the University of Minnesota. He is at present carrying on a research on the Relative Rates of Elimination of Oxidizible Elements in Cast Iron. Address Professor Moffett at the University of Minnesota.

C—RESEARCH PROBLEMS

The purpose of this section of Engineering Research is to bring together persons who desire cooperation in research work or to bring together those who have problems and no equipment with those who are equipped to carry on research. It is hoped that those desiring cooperation or aid will state problems for publication in this section.

Highways C1-22. COORDINATION OF HIGHWAY RESEARCH. *See Road Materials and Equipment C1-22.*

Road Materials and Equipment C1-22. COORDINATION OF HIGHWAY RESEARCH. Mr. W. K. Hatt, a member of the Advisory Board on Highway Research of the National Research Council, discusses this subject completely in a paper read at the meeting of the American Association of State Highway Officials, Omaha, Neb., December, 1921. He discusses first the present situation in highway research and then points out how the various state highway commissions may assist in developing as rapidly as possible the data which can be a safe foundation for the scientific construction and operation of highways. Address A. D. Flinn, Chairman of Division of Engineering, National Research Council, 29 West 39th St., New York.

D—Research Equipment

The purpose of this section of Engineering Research is to give in concise form notes regarding the equipment of laboratories for mutual information and for the purpose of informing the profession of the equipment in various laboratories.

E—Research Personnel

The purpose of this section of Engineering Research is to give notes of a personal nature regarding the personnel of various laboratories, methods of procedure of commercial work or notes regarding the conduct of various laboratories.

Research Agencies E1-22. Personnel Research Agencies. The Bureau of Labor Statistics of the U. S. Department of Labor has just issued a 107-page Bulletin No. 299 in which it has attempted to provide information about all existing agencies in the United States in the field of Personnel Research. Personnel research has been construed to include within its scope studies and investigations of all kinds concerned with any of the problems of (*a*) employment management and industrial relations (such as selection and placement of employees, job analyses and specifications, rating and grading, lines of promotion, labor turnover, absenteeism, wage and other incentives, joint control, etc.); (*b*) vocational psychology, including the development and standardization of intelligence and trade tests; (*c*) training of managers, foremen and workmen, either in schools and colleges, in the factory, or under schemes of coöperation between educational institutions and industrial establishments; (*d*) working conditions in relation to output, including hours of labor, fatigue, lighting, ventilation, food; (*e*) health hazards and occupational diseases; (*f*) safety codes and appliances; also the special problems connected with the employment of women and young persons, foreign-born workers and colored workers, the handicapped or disabled, and the mentally deficient or unstable. The agencies whose activities are described are arranged in the following main divisions:

1 Official agencies: (*a*) Federal, (*b*) State, (*c*) Municipal.
2 Non-official agencies: (*a*) Associations, foundations, research bureaus, and institutions; (*b*) Universities and colleges.

Address Bureau of Labor Statistics, Washington, D. C.

Research Agencies E2-22. New Division of Coöperative Research. Under the Directorship of Dr. W. V. Bingham, the Carnegie Institute of Technology has recently organized a Division for Coöperative Research. This is new evidence of efforts of the Institute to foster research of the highest order in all the scientific and technical departments of the Institute. The plan and purpose of the organization of this new activity of the Carnegie Institute is outlined in the November, 1921 issue of "*The Carnegie Technical Journal* under the heads, The Need for a Research Center, Industrial Problems, Commercial Problems, Educational Research, and Organization and Program of the New Division. Address Carnegie Institute of Technology, Pittsburgh, Pa.

F—Bibliographies

The purpose of this section of Engineering Research is to inform the profession of bibliographies which have been prepared. In general this work is done at the expense of the Society. Extensive bibliographies require the approval of the Research Committee. All bibliographies are loaned for a period of one month only. Additional copies are available, however, for periods of two weeks to members of the A.S.M.E. These bibliographies are on file at the office of the Society.

Cement and Other Building Materials F1-22. Acid-Proofing of Concrete. A bibliography of $2^{1}/_{2}$ pages. Search 3472.

Cement and Other Building Materials F2-22. Waterproofing of Concrete. $5^{1}/_{2}$ pages. Search 3473.

WORK OF THE A.S.M.E. BOILER CODE COMMITTEE

The Boiler Code Committee meets monthly for the purpose of considering communications relative to the Boiler Code. Any one desiring information as to the application of the Code is requested to communicate with the Secretary of the Committee, Mr. C. W. Obert, 29 West 39th St., New York, N. Y.

The procedure of the Committee in handling the cases is as follows: All inquiries must be in written form before they are accepted for consideration. Copies are sent by the Secretary of the Committee to all of the members of the Committee. The interpretation, in the form of a reply, is then prepared by the Committee and passed upon at a regular meeting of the Committee. This interpretation is later submitted to the Council of the Society for approval, after which it is issued to the inquirer and simultaneously published in Mechanical Engineering.

Below are given the interpretations of the Committee in Cases Nos. 375 and 376, as formulated at the meeting of December 6, 1921, and approved by the Council. In accordance with the Committee's practice, the names of inquirers have been omitted.

Case No. 375

Inquiry: Is it permissible, under the requirements of the Boiler Code, to weld a seam in a vertical firebox not over 38 in. in diameter, and in length ranging from 20 in. up, by the autogenous or fusion process where the firebox has no support other than the tube sheet, mud ring and fire door?

Reply: It is the opinion of the Committee that, under the requirements of the Code, autogenous or fusion welding is not permissible for the seam in the firebox of a vertical-tubular boiler, unless the sheet containing the seam is supported by staybolting.

Case No. 376

Inquiry: An interpretation is requested of the limitation of 50 hp. in Par. 318 of the Boiler Code to different classes of boilers. Is it the intention that the horsepower capacity be based on water heating surface as specified in the requirement in Par. 274?

Reply: It is the opinion of the Committee that the intent of Par. 318, relative to the determination of the feeding devices required for boilers, will be met if boilers having over 500 sq. ft. of water-heating surface are provided with two or more feeding devices.

Boiler Code Sub-Committee on Code for Care of Steam Boilers in Service

When the A.S.M.E. Boiler Code Committee was appointed in 1911, it was given the following title: Committee to Formulate Standard Specifications for the Construction of Steam Boilers and Other Pressure Vessels and for Their Care in Service. Since its inception however, the great volume of the Committee's work has been devoted to the formulation of rules for the construction of steam boilers of different classes and little opportunity has been given to consider the important problem of their operation.

Realizing this lack in the Committee's function, attention has recently been given to the need for operating rules and there was appointed by the Council at the meeting of January 7, at the request of the Boiler Code Committee, the following Sub-Committee for this purpose:

F. M. Gibson, *Chairman*, Boston, Mass.
H. F. Scott, Framingham, Mass.
J. R. Gill, Meadville, Pa.
W. H. Larkin, Jr., Passaic, N. J.
J. Wolff, Cleveland, O.
W. G. Diman, Manchester, N. H.
J. S. Schumaker, Lincoln, N. H.
E. G. Bailey, Cleveland, O.
J. W. Hays, Michigan City, Ind.
S. F. Jeter, Hartford, Conn.
Nicholas Stahl, Providence, R. I.

This Sub-Committee consists of active operating engineers who have had long and varied experiences and are eminently fitted for the preparation of rules for the care of boilers in service. The code which they may formulate should be welcomed by all boiler owners, insurance companies and in fact anyone directly or indirectly interested in the field of steam boilers or other pressure vessels.

The Boiler Code Committee desires coöperation in this new department of its activities and requests everyone interested to assist in this important work for the general good. Mr. F. M. Gibson, to whom the Committee is indebted for the active effort in inaugurating this work and who has been appointed Chairman, will greatly appreciate the assistance of all those who may contribute.

He should be addressed care of the American Sugar Refining Co., 49 Granite St., South Boston, Mass.

Bombing of the U. S. S. "Ex-Iowa" and the Former German Ships

By COMMANDER F. J. CLEARY,[1] U. S. N.

IN agreeing generally to Mr. Elmer A. Sperry's editorial on "What the Virginia Capes Aircraft Bombing Test Show" in the September, 1921 issue of Mechanical Engineering I desire to point out that some of his statements taken by themselves are susceptible of erroneous conclusions. The bombing experiments are of sufficient value to warrant presentation of the facts observed and the conclusions reached by the Board of Observers and by the Army and Navy Joint Board.

The bombing of the U. S. S. ex-*Iowa* and of the ex-German ships, including the *Ostfriesland*, was conducted by the Naval Air Force of the Atlantic Fleet under Admiral Henry B. Wilson, Commander-in-Chief. The Army was invited to participate and did so by a Provisional Air Brigade operating under the orders of the Commander-in-Chief, Atlantic Fleet. The plans for the experiments were set forth in Fleet Operations Order 261–24–5 of May 25, 1921, from which the following extracts are taken:

"Vice Admiral H. P. Jones, Commander Battleship Force, is in charge of operations scheduled."

"The Commander of the Air Force Atlantic Fleet is charged with the operations of all Air Forces engaged."

"Brigadier General William Mitchell, U. S. Army, has been designated by the War Department as the Commander of the Army Provisional Air Brigade and is in immediate command of all Army Air Forces engaged in these exercises."

The *Ostfriesland* was 50 miles from the coast, and the attacking planes were guided to the target by a double line of destroyers stationed for that purpose and to aid any planes taking the water.

The ex-*Iowa* was approximately 100 miles off shore, and the search for and the bombing of her were conducted by Navy planes. Three army blimps took part in the search operations. The Army was invited to take part in the bombing of the ex-*Iowa*, but did not.

The Army was also represented on the Board of Observers, composed of 13 Naval Officers (ranking from Captain down to Lieutenant Commander) and 6 Army Officers (Lieutenant-Colonels and Majors), 3 of the Army Air Force and 3 of the Ordnance Department.

The *Ostfriesland* was turned over to the U. S. with the understanding that she would be sunk, and the bombing experiments were planned to cause as much destruction as possible so that any weak features of construction would be revealed. She was an old ship, laid down in 1909 and launched in 1911, and displaced 24,000 tons, and her protection above and below water was much less effective than in a modern ship. She had no anti-aircraft gun fire and could not maneuver to avoid attack, and the planes bombed from the extremely low altitude of 1200 to 2000 ft. The ship had been badly damaged by the Germans before she was delivered. She leaked to such an extent that on the trip down from New York to her anchorage she took in 1020 tons of water increasing her draft one foot.

The bombing on the first day lasted from 1:40 to 4:25 p.m., during which time 52 planes, both singly and in formation, made 31 flights over her, dropped 52 bombs and made 13 direct hits as follows:

Navy	33–230-lb. bombs 8 hits
Navy	8–550-lb. bombs 4 hits
Army	11–600-lb. bombs 1 hit

At the end of the first day's bombing, the ship had received little damage from the direct hits, except a hole in the starboard side of the forecastle made by a 600-lb. bomb which caused some general damage to light fittings under this deck. A few holes were made by fragments in the second deck, but this second deck practically stopped the whole force of the explosion. No damage whatever was done to the protective deck.

A number of these bombs had fallen close aboard. Examination below showed 7 of the 9 fire rooms clear of water, one fire room could not be entered, the other was taking in water. Two out of the three engine rooms were taking in water. This water was from the old leaks and from new leaks, but the water was coming in so slowly that the ship could have been pumped out by the powerful outfit of pumps which are a part of the machinery equipment of all naval ships The ship took in water during the night so that the next morning her draft had been increased by an additional 3 ft , showing that she now had 4080 tons of water in her (which could have been kept clear had she been in good condition at the beginning and had the pumps been operating), bringing her water line within 1 or 2 ft of the 3d-deck air ports.

Bombing with 1000-lb. bombs commenced at 8:30, and during the morning 11 Army planes made 11 single flights over her, dropping 11 1000-lb. bombs and making three direct hits. A careful inspection was made. The three direct hits caused no vital damage to the ship and none to her main battery; two of these 1000-lb. bombs detonated between the two starboard waist turrets but no damage to the turrets resulted. The other bomb blew a hole in the starboard side of the forecastle extending down near the water line. This injury would have undoubtedly affected the speed of the ship; there was no bursting effect below the 2d deck and all fragments were stopped by the protective deck. The damage in every case where bombs struck the ship was purely local; the vertical blast effect was considerable but the horizontal blast effect was so comparatively slight that a 1 inch steel bulkhead about 25 ft. from the point of impact would have afforded protection to personnel. No damage was suffered to the battle lighting and battle control systems and absolutely no damage was caused behind armor or below the protective deck. By noon, from the water taken aboard through the leaks, the ship was down 5 feet by the stern.

Bombing with the 2000-lb. bombs was commenced at 12:30 in 12½ min. 6 bombs were dropped—there were no direct hits. Three bombs dropped far enough away to do no damage; the other three dropped very close alongside, one detonated very close to the port bow but appeared to do no appreciable damage; the third detonated under water close to the port quarter severely damaging the already weakened port side and at the same time blew in the glass air ports of the gun deck and 3d decks aft, these ports being awash and not fitted with steel battle covers as is usual. This allowed a heavy rush of water into the already waterlogged hull. The vessel began to settle rapidly by the stern, listed heavily to port, and at 12:40 she turned completely over and went down by the stern throwing her bow high in the air.

In all the following bombs were dropped on the *Ostfriesland:*

	Direct hits
33 Navy– 230 lb.	8
8 Navy– 550 lb.	4
11 Army– 600 lb.	1
11 Army–1000 lb.	3
6 Army–2000 lb.	0
69	16

The damage done by the bombs was identical to the damage that would have been caused by mines.

The mining effect on the underwater structure by the bombs which detonated under water close to the ship, together with the flow of water through the equalizer pipes and the fire-room doors (which were opened by the Board of Observers to keep the ship on an even keel) and the rush of water through the blown-in glass air ports caused her to sink finally. All this was cumulative, and it is probable that if she had been manned, her pumps could have controlled the leakage resulting from all attacks but the final one, and consequently the mining effect of the final attack would have been greatly reduced, and it is very possible that sinking might not have resulted from the damage inflicted by all of these attacks. Our latest capital ships are so constructed that the damage from these attacks would have been very much less than that inflicted on the Ostfriesland.

At an immovable target 548 ft. long by 94 ft. beam and at the low altitude of 1200 to 2000 ft. 16 direct hits were made out of 69 shots, the misses varying from close aboard to 300 ft. distant.

Contributions of interest to the profession are solicited. Communications should be addressed to the Editor.

The Development of the Colorado River

The convention of the League of the Southwest at Riverside, California, on December 8 to 10 and the hearing on the Boulder Canyon Project before Secretary Fall at San Diego on December 12 has aroused general interest in the various proposals which have been made for the development of the Colorado River. The basin of this river includes parts of Arizona, California, Colorado, Nevada, New Mexico, Utah and Wyoming, and has an area of about 250,000 square miles. It contains some five million acres of irrigable lands, and has power possibilities aggregating six million horsepower. Its most pressing problem, however, is flood protection.

Clinedinst

O. C. Merrill

The Gulf of California originally extended northwestward into California. The silt-laden water of the Colorado gradually formed a delta extending across the Gulf, cutting off the northern end, and deflecting the flow of the river wholly to the south. The waters inclosed in the northern and evaporated leaving a depression, now known as the Imperial Valley, and the Salton Sea with its surface 250 ft. below sea level. The silt-formed delta is unstable; the river is constantly depositing more sediment and shifting its channel back and forth over the flat ridge—some 30 ft. above sea level—which forms the crest of the delta; and there is danger at each flood season that it may break northward into the Imperial Valley instead of continuing southward into the Gulf. The river did break through in 1905 and for a year and a half discharged into Salton Sea before it was turned back with great difficulty and much expense into its old channel. The levees which were later built to protect the valley have several times been awash in periods of floods; it is necessary to raise them about a foot a year to keep pace with the rise of the river channel; and it is only a matter of time when the river will break through again unless steps are taken to control the floods. It is this situation which has placed primary emphasis on flood control in all plans for the development of the Colorado River.

Less than one acre in thirty in the Colorado Basin is irrigable. The general development of the basin will, therefore, be likely to require all the agricultural products that its lands can produce long before there will be a demand for all its potential water powers. For this reason irrigation is secondary only to flood control in a general plan of development, and irrigation use of the waters of the stream will take precedence over power use wherever these uses conflict.

Although the Colorado Basin has important mineral resources, only partially developed on account of lack of power and of transportation, and has several lines of trunk railroads and many flourishing towns and cities, all of which would serve to create a demand for power, the individual markets would be so small and so widely scattered that it is hardly probable that the requirements of the basin itself would justify any large-scale development on the main river at the present time. Such a development must first seek primary markets outside the basin. The only section which seems capable of furnishing the requisite demand in the near future is Southern California; and all proposals for extensive development on the river have that territory in view. If, however, primary lines are once established and the main load secured, extension of service will be made into the local territory, provided the projects are operated by agencies which have the authority and the disposition to extend their lines for such purpose.

Applications for power projects on the Colorado and its tributaries aggregating 4,500,000 primary horsepower are now on file with the Federal Power Commission. The most important of the proposed projects are the Lees Ferry Project of the Southern California Edison Company, the Diamond Creek Project of James B. Girand, and the Boulder Canyon Project of the United States Reclamation Service. The first proposes a dam near Lees Ferry of approximately 500 feet in height forming a reservoir 125 miles in length with a capacity of 30 million acre feet and capable of producing 600,000 horsepower from the regulated flow of the stream. The Diamond Creek Project involves a dam some 250 feet high, has no provision for seasonal storage, and would be capable of producing some 125,000 horsepower from the unregulated flow of the stream. The Boulder Canyon Project proposes a dam 550 feet in height forming a reservoir of 30 million acre feet capacity. This project, while intended primarily for flood control and irrigation would be capable of producing 600,000 horsepower. The Boulder Canyon Project is approximately 250 miles from Los Angeles, and the Lees Ferry Project 450 miles. The Diamond Creek Project midway between the other two is intended primarily for supplying power in Arizona.

The general problem of the Colorado River Development and the relation to each other of flood control, irrigation and water power can best be understood by reference to the accompanying map and profile and by a consideration of the different characteristics of the upper, middle and lower sections of the river. The upper section from the headwaters to the mouth of the San Juan comprises about 40 per cent of the area of the basin and affords about 87 per cent of the total runoff, or an average of 15,000,000 acre ft. per annum. In this section are some 2,500,000 acres of irrigable land, one-half of the total in the basin. It also has power possibilities aggregating 2,000,000 horsepower. In this section, both upon the main stream and upon its tributaries are many favorable reservoir sites by means of which it would be practicable to regulate the flow of the streams for irrigation within the section, for power development both within the section and outside, and, if desirable, for flood control on the lower river.

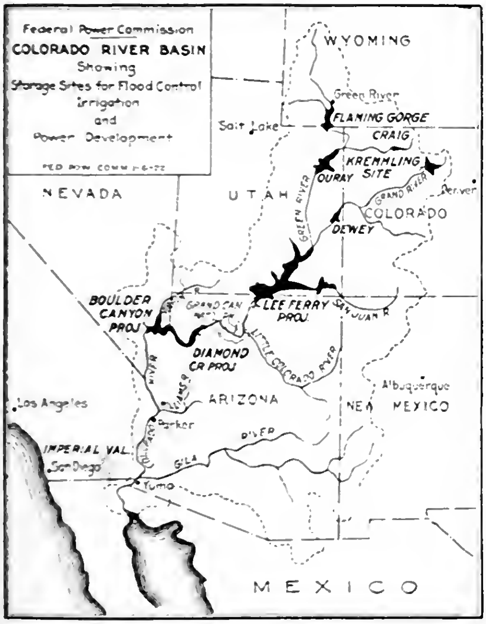
The middle section from the mouth of the San Juan to the mouth of the Williams comprises about 35 per cent of the area of the basin and supplies about 7 per cent of the annual runoff. There are no irrigable lands along the river in this section and only 250,000 acres on the tributaries, none of which can be reached from the main river. In this section, however, there is a total drop of some 3,000 ft., capable, if fully utilizing the average annual runoff entering the section, of producing 4,000,000 horsepower. Except for the Boulder Canyon Site near the lower end of the section there are no feasible storage sites. Dams erected for power development would be primarily for the purpose of concentrating the head and of providing daily load regulation. Seasonal regulation would be dependent upon storage in the upper section.

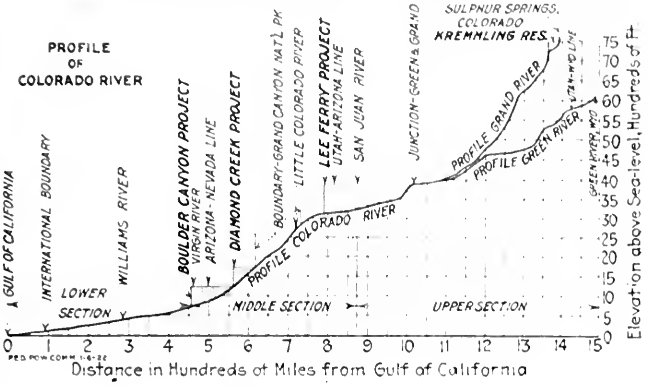
The lower section from the mouth of the Williams River to the Gulf, and including the drainage of the Gila and the Imperial and

Coachella valleys in California, comprises some 25 per cent of the total area of the basin and furnishes about 6 per cent of the average annual runoff. Its power possibilities are relatively unimportant, but it contains some 2,250,000 acres of irrigable land, the most fertile and most valuable in the basin.

Viewed solely from the physical standpoint, the upper section of the basin might have its primary development directed either toward irrigation or toward water power. On the other hand, the middle section, with the exception of storage below the mouth of the Virgin and of relatively small irrigable areas on the tributaries, is suitable only for power development. Equally clearly the lower section should be devoted primarily if not exclusively to irrigation. The primary elements of a general plan for river development for the several purposes are, therefore, storage at the headwaters for irrigation and power in the upper section, storage below the San Juan for the regulation of the waters available at that point for power use in the middle section, and storage below the Virgin for re-regulation to meet irrigation requirements and flood protection in the lower section. If these can be provided, and an equitable distribution of irrigation waters between the upper and lower sections effected, the fullest utilization of the stream can be effected with the least conflict of use.

There seems to be a reasonably close agreement on the general features of a plan of development. Such disagreement as has appeared has had reference to the order in which the various steps of the general plan should be undertaken and to the agencies which should carry it out. It is agreed that flood control is the most pressing problem. This could be effected by storage in the upper section,—which was the original proposal—but such a plan would require the use of several of the best reservoir sites in this section, and would render them practically useless for irrigation or power development. Flood control could also be effected by storage either below the mouth of the San Juan at the upper end of the middle section or at Boulder Canyon at the lower end of the section. Storage primarily for flood control and irrigation at the former location would at the same time provide all the regulation likely to be needed for many years for power development below although eventually when power demands called for the entire use of the upper reservoir for such purposes, storage below the Virgin would be required for re-regulation to meet the needs of irrigation and flood control. On the other hand, if the sole dependence for flood control and irrigation storage is to be placed on the Boulder Canyon site, the investment must be duplicated above in order to provide regulation for power purposes in the middle section, and when this has been done the greater part of the storage capacity at Boulder Canyon will be valueless, unless the excess cost can be justified wholly from the standpoint of the power which may be produced, or unless the imminence of flood danger to the Imperial Valley and the time element in favor of Boulder Canyon justify the additional cost as a measure of insurance.





It was the consensus of opinion at the San Diego hearing that the Boulder Canyon dam, at least, should be built and owned by the United States and that the power produced should be disposed of by the United States. The Boulder Canyon site is estimated to be capable of producing 500,000 horsepower, and the only market for such a block of power at the present time is in Southern California. Under such circumstances there is not likely to be any further move made toward large-scale development upon the river until Congress either approves or disapproves the proposal for Government construction and, if it approves, until the question of the distribution of the power is settled. The municipalities of Southern California, particularly Los Angeles, are making a strong bid for this power. If they secure it, it will be taken out of the basin, will not be a factor in the development of the basin itself, and the other six States which have not the means to enter upon a program of public development will either have to wait until local demands have increased to an amount which will justify private capital in undertaking the service, or depend upon the Federal Government to supply their needs from Boulder Canyon or elsewhere.

O. C. Merrill.[1]

A.S.M.E. Announces Spring Meeting Plans

At the meeting of the A.S.M.E. Council held in Norfolk, Va., on January 7, the Committee on Meetings and Program received full support in its stand that papers for the 1922 Spring Meeting must be in hand before March 15. This action was taken to permit the Committee to give proper consideration to contributions for the meeting. The time limit is also set to insure printing and issue previous to the meeting. In this way proper discussion is provided and it is the consensus of opinion that discussion is necessary to the life of a meeting. At the last Annual Meeting, papers were ready only a few days before the professional sessions started and as a result, some of the notable papers did not receive the study their contents really required. Many members expressed dissatisfaction which it is believed this Council action will remove in the future. It should be borne in mind, however, that March 15 is the last date that papers will be accepted. All of the papers can not be properly handled if they arrive at the last moment, and the Committee on Meetings and Program will exercise its judgment as to the papers that should be printed.

The adoption of this procedure at this time is especially fortunate as it will give considerable strength to the program of the Spring Meeting at Atlanta.

An exceedingly interesting Spring Meeting week has been tenta-

---

[1] Executive Secretary, Federal Power Commission, Washington, D. C.

tively decided upon by the A.S.M.E. Committee on Meetings and Program. The festivities will start at the University of Virginia on Friday and Saturday, May 5 and 6, preceding the meeting. This will give an opportunity to members attending from the North to stop over and enjoy the hospitality of the Virginia Section. The program at Atlanta will start on Monday, May 8, and will extend through May 11. The Atlanta Section is offering a remarkable program of entertainment in which a real southern barbecue and exhibition golf match will be offered. The climate in Atlanta at that time of the year is very pleasant and those coming from other sections of the country not so well favored will enjoy the week out of doors well in advance of the open season in the North.

The technical program in Atlanta will include papers furnished by the Power, Fuels, Materials Handling, Management, Machine Shop and Textile Professional Divisions.

The Power Division will present a program relating to hydroelectric power development, particularly in the Southeast. A paper giving the results of recent tests on the 60,000 kw. turbine of the Interborough Rapid Transit Company of New York City will be presented by title.

The Fuels Division promises three papers as follows:

Relation of combustible elements of coal to the oxygen content and the establishment of a fuel unit of practically constant heat value for over 90 per cent of all bituminous coals, E. A. Uehling. Boiler Room Performance and Practice at the Colfax Station of the Duquesne Light Company and the Seward Station of the Pennsylvania Public Service Corporation, C. W. E. Clarke. Reduction of Fuel Wastes in the Steel Industry, F. G. Cutler.

Materials Handling Equipment in the Steel Industry is the subject of a paper to be given before the Materials Handling Division by F. L. Leach of Perin and Marshall. Mr. Leach has treated the entire industry in a comprehensive manner and shows how its operation hinges on adequate design of equipment.

The programs of the Management, Textile, and Machine Shop Divisions treats of the problems of the textile industry. The Management Division plans three papers as follows: Comparison of Southern white labor with foreign labor of the North, Frank H. Neely. General subject of management in textile plants, George S. Harris. Reducing costs in textile mills by increasing production, E. A. Lucey.

The Machine Shop and Textile Divisions will coöperate in joint sessions on textile machinery. The papers will discuss textile machinery maintenance, weaving, ginning, and carding machines.

After the sessions at Atlanta those interested in seeing textile plants in operation will visit Greenville, S. C., where thorough inspection trips will be held. Other members of the Society will be given an opportunity to take a trip to Birmingham, Ala., where the remarkable series of plants engaged in the manufacture of iron and steel will be inspected.

Patent Relief Bill Passes House

As we go to press, word is received from Chairman Edwin J. Prindle, of the American Engineering Council Committee on Patents, advising that the Lampert Patent Office Bill has passed the House of Representatives. This is the first step in securing the much needed relief in the Patent Office for which the American Engineering Council has been struggling for considerable time.

Engineering Societies Library Now Loans Books

In the book column on page 139 Director Craver of the Engineering Societies Library explains the plan by which members of any of the Societies participating in the library may have books loaned to them.

In the early days of the Society when the membership was not so widely scattered or its interests so diversified, the library privileges were more generally appreciated than at the present time. Technical book publications, which are usually expensive, are still needed for reference and this new attempt on the part of the Library to satisfy the demand from outside the environs of New York City is particularly noteworthy. This step is along the line of the photostat and search services in placing the resources of the library at the disposal of the individual members of the profession.

Industrial Standardization

E. C. Peck

We are apt to think of mass production as primarily an American development, but the experiences of the War brought its possibilities home to the leaders of industry in the principal European countries, even if all of them had not realized its significance before. Today there are being planned and carried out in each of these countries, far-reaching programs of industrial standardization. In a large measure, the work is national in its scope. That is to say, any particular piece of work is carried out through the systematic coöperative effort of the industries concerned, functioning through their national industrial associations, technical societies, and government bureaus.

The two countries in which such work has reached its greatest development, both in scope and in activity, are Great Britain and Germany. A description of the German work is presented on page 136 of this issue. The Germans, taking full advantage of the lessons of the War, are making industrial standardization an essential part of their scheme of reconstruction and are relying on it to play an important role in rebuilding their foreign trade on a vastly increased scale. Managers of American industries may well give serious study to the German work. It behooves them to intensify their efforts toward standardization, or they will be left behind in the competition for world commerce. It is not enough that there be standardization work done by sections of industries and by individual firms, although such work, prior to the War, made possible a considerable amount of mass production, which attracted the attention of European industrialists. To reap the full benefits the work must be broadened and intensified, and made national in its scope. This requires the joint effort of manager and engineer, of producer, distributor, consumer and independent specialist, all speaking through the organized bodies which represent their interests. Fortunately such industry-wide coöperation has already been brought about in a large number of projects now going forward under the auspices of the American Engineering Standards Committee, and very substantial results have already been achieved. It must be evident that considerable prestige is acquired by manufacturers whose products are in accord with the standards that have been established by national organizations and especially those approved by the American Engineering Standards Committee.

The many benefits of standardization are by no means limited to the production side. In the long run standardization is bound to be of even greater importance in the reduction of distribution and selling costs,—perhaps the most important problem of our economic system. A comprehensive program of standardization planned and carried out by our great national industries will mean the saving of hundreds of millions—even billions of dollars.

E. C. Peck[1]

Ordnance Department Needs Manufacturers' Aid

With the passing of emergency, the Ordnance Department of the Army, which during the war was able to enlist close and hearty coöperation from manufacturers of ordnance material and mechanical engineers generally, is now finding it difficult to secure from private industry the assistance which is so necessary if the most practical types of ordnance material are produced. It is essential to the national interest that this apathy on the part of outside manufacturers be broken down, in the opinion of Brigadier General W. S. Peirce, assistant chief of Ordnance, in immediate charge of the work which involves this problem. He is at this time making a renewed effort to solve this problem.

General Peirce believes that a widely held view that ordnance specifications are too theoretical, can be offset entirely if machinery and material manufacturers can be interested sufficiently to go into the subject deep enough to understand the military problems involved.

[1] General Supt., Cleveland Twist Drill Co., Chairman A.S.M.E. Standardization Committee.

BOMBING OF THE U. S. S. "EX-IOWA"

(Continued from page 131)

That accuracy of bomb dropping rapidly decreases with increase of altitude and a moving target is proved by the bombing tests on the ex-*Iowa* a few days earlier when 22 planes bombed her from 11:24:00 a.m. to 3:10 p.m. from an altitude of 4000 ft. dropping 85 (dummy) bombs and making 2 direct hits, the 83 misses varying from close aboard to 600 or 700 ft. distant. The speed of the ex-*Iowa* was only 6 knots which should have had little or no effect upon the accuracy of bomb dropping.

The problem of avoiding a bombing plane by maneuvering or of hitting a bombing plane is much simpler than avoiding or hitting a plane not bombing for the reason that the bombing plane must steady on a course heading almost directly toward the target for an appreciable period and the position at which the bomb must be released can be forecast with fair accuracy.

If the *Ostfriesland* had been underway at 20 knots or more and if her anti-aircraft battery had been in action, keeping the heavy bombing planes at a safe altitude of 6000 ft., it is reasonable to believe that the chance of serious damage would not have been very great from the 69 bombs which were dropped at her during the two-days attack. If, in addition, she had carried three or four fast pursuit planes (with machine guns firing explosive and incendiary bullets), as all capital ships now carry or will carry, these fast planes would have outmaneuvered and shot down a number of the bombing planes before they arrived within bombing distance.

The Navy has known for many years that any ship could be seriously damaged or sunk by detonating heavy charges of high explosive under water against or very close to the body of the ship below armor. Such damage from mines or torpedoes has been guarded against by numerous watertight bulkheads or by the British "blister" until the latest capital ships can survive direct hits from two or three torpedoes or the explosion of two or three heavy mines fairly close aboard.

If the explosion takes place beyond a certain distance from the ship (depending upon the weight of the explosive charge and its distance below the surface) little or no damage will result. The distance within which a charge of high explosive must be placed to seriously damage the thin plating below armor is comparatively very short; for instance—a 250- or 300-lb. bomb detonated under water probably within 15 or 20 ft. of the hull of the light cruiser *Frankfort* without appreciable effect.

The Navy fully believed that very heavy charges of high explosives could be detonated on the upper decks of a modern capital ship with no damage to turrets or other heavy fittings, and while such heavy charges would probably penetrate the upper decks, the heavy protective decks would render the propelling machinery boilers, magazines, and the greater part of the personnel immune, from overhead attack.

This knowledge and this belief have been confirmed by the experiments on the ex-*Iowa* and the *Ostfriesland*, and the Navy faces the same problem—to keep high explosive charges from detonating under water within the comparatively short danger space of the underwater body below armor.

Under the same conditions, i.e., a stationary target and immunity from hostile fire, an attack by destroyers, by submarines, or by another battleship would have resulted in sinking the Ostfriesland in a very short space of time.

The experiments demonstrated that the airplane is a powerful weapon of offense, capable under favorable conditions of placing heavy charges of high explosive sufficiently close to a capital ship to sink her eventually. The airplane menace to the capital ship is commensurate with the destroyer menace and the submarine menace. The destroyer menace was met by numerous watertight bulkheads, rapid fire guns and protecting destroyers; the added submarine menace was met by the added protection of listening devices, depth charges, speed and quick maneuvering, the added airplane menace is being met by the added protection of (first and most important) fast pursuit planes, and anti-aircraft batteries.

The Joint Army and Navy Board consists of the following very able and experienced officers: General Pershing, Chief of Staff; General Harboard, Director of the Operations Division, General Staff; General Haan, Director of War Plans Division, General Staff; Admiral Coontz, Chief of Naval Operations; Admiral Williams, Director of Plans Division, Naval Operations; Captain Cole, Assistant Chief of Naval Operations. This Joint Board, from a careful study of the reports of the Boards of Observers, from actual observations by some of the members of the Joint Board of the bombing experiments, and from their general knowledge of the principles of war and methods of conducting war, arrived at certain general conclusions. These general conclusions are concurred in by a large majority of officers of both the Navy and the Army who have had access to the report of the Joint Board. These general conclusions have been approved by the Secretary of War and the Secretary of the Navy and are quoted below:

> "Aircraft either singly or in combination have pronounced ability to search sea areas within their radius of action and to locate naval vessels operating in such areas. When armed with heavy bombs the radius of action of heavier-than-air types is inadequate for extensive search operations. Darkness, fog, falling or squally weather will greatly reduce the effectiveness of aircraft in search operations.
>
> "Inasmuch as these experiments were not conducted under battle conditions it is difficult to draw conclusions as to the probability of hitting a target with bombs from aircraft while in action. Under the favorable conditions existing during the experiments, namely stationary or practically stationary targets, immunity from enemy interference, excellent visibility and flying conditions, the percentage of hits was greatly in excess of that to be expected under battle conditions. The probability of hitting will be reduced in the case of a target moving at high speed on varying courses; further reduced if the target vessel is protected by effective anti-aircraft armament; and will be practically negligible if the target is protected by effective pursuit planes. The effectiveness of the bomb carried by aircraft emphasizes the necessity for the rapid development of anti-aircraft armament and the provision of pursuit planes as a part of the fleet. Aircraft carrying high-capacity high-explosive bombs of sufficient size have adequate offensive power to sink or seriously damage any naval vessel at present constructed provided such projectiles can be placed in the water alongside the vessel. Such bombs hitting the upper works of the vessel are disastrous to exposed personnel, serious to light upper works, comparatively slight to heavy fittings such as guns, and negligible to turrets. The effect of direct hits was completely local. In the case of capital ships, the mining effect of bombs will be materially reduced due to the ability of the personnel to free the ship of large quantities of water by means of pumps and to shore up watertight doors and bulkheads which are in danger of carrying away due to water pressure. Aircrafts possess sufficient offensive power to seriously threaten the exposed personnel of naval vessels unless such vessels are protected by pursuit planes. This emphasizes the necessity for the further protection of personnel and for the provision of aircraft carriers to accompany the fleet.
>
> "The radius of action of bombing planes limits their effectiveness against Naval vessels to coast defense or base defense.
>
> "The mission of the Navy is to control vital lines of transportation upon the sea. If no opposition is met from enemy naval vessels this mission can be accomplished without entering an enemy's coast zone within which bombing aircraft based on shore are effective.
>
> "Without an effective Navy in time of war a nation must submit to an economic blockade fatal to its trade and the importation of necessary materials for the production of war supplies.
>
> "If heaver-than-aircraft are to be effective in naval warfare they must have great mobility, and since their radius of action is not great, additional mobility must be obtained by providing aircraft carriers. So far as known, no planes large enough to carry a bomb effective against a capital ship have been flown from or landed on an airplane carrier at sea. Future development may make such operations practicable. Aircraft carriers are essential to the highest efficiency of the fleet. Aircraft carriers are subject to attack by vessels carrying guns, torpedoes or bombs, and will require, as all other types of vessels require, the eventual support of the battleship.
>
> "The battleship is still the backbone of the fleet and the bulwark of the Nation's sea defense, and will so remain as long as safe navigation of the sea for purposes of trade or transportation is vital to success in war. The airplane, like the submarine, destroyer and mine, has added to the dangers to which battleships are exposed, but has not made the battleship obsolete. The battleship still remains the greatest factor of naval strength. The development of aircraft, instead of furnishing an economical instrument of war leading to the abolition of the battleship, has but added to the complexity of naval warfare.
>
> John J. Pershing,
> Senior Member.
>
> Approved
> Theodore Roosevelt,
> Acting Secretary of the Navy.
>
> Approved
> John W. Weeks,
> Secretary of War."

Every new development in naval warfare has its advocates who have predicted that the battleship was doomed. First, the small torpedo boat was to render the battleship obsolete; next the fast destroyer, then the submarine, and now the airplane—each new challenge to the supremacy of the capital ship has been met by the development of the defense and by adopting and adapting the challenger as an efficient auxiliary to the capital ship, and the Navy is dealing with the airplane in the same manner as it has successfully dealt with the torpedo boat, the destroyer and the submarine.

Engineering and Industrial Standardization

Industrial Standardization in Germany

INSUFFICIENT attention has been given to the role which standardization is playing in German industrial reconstruction. The German industries are planning and are carrying out a far-reaching program of standardization as a necessary step in building up an unprecedented industrial structure which must rest in large measure on an extensive foreign trade. In no other country except Great Britain is standardization work being carried on upon a scale, or with an intensity, comparable to that in Germany.

The German work is of special interest to those responsible for the management of American industries, not only because of its importance, but also because of the similarity in the historical conditions surrounding the national standardization movements in Germany and in America.

Prior to 1917 a vast amount of standardization work had been carried out in Germany by individual companies, and by engineering societies and industrial associations, but, as was the case in America before the organization of the American Engineering Standards Committee, the work had not been unified along national lines.

As has been the case with all the other national standardizing bodies except the British, which was organized in 1901, the success of the standardization work carried out by the various countries during the World War as a part of their national conservation programs, was a chief cause of the formation of the Central German Body. It is called the Normenausschuss der Deutschen Industrie, and was organized by the Verein deutscher Ingenieure, at the suggestion of the German Government in 1917. The present membership consists of engineering societies, industrial associations and government ministries, and in addition there are 700 firms who are contributing members. The work of the Normenausschuss deals only with those subjects which concern two or more industries or branches of industry.

It is remarkable that the national standardization movement in Germany should have been so thoroughly organized and that so much work should have been accomplished in four years. 144 approved standards sheets have been issued and over 500 others have been so far developed that they have been published in tentative form. The standards are issued under the general designation of German Industrial Standards (Deutsche Industrie Normen, usually contracted to the slogan "DINORM"). The Germans were the first of the national bodies to publish standards in loose-leaf form. The work is so divided as to make each sheet as nearly independent as possible. Firms purchase these sheets in quantity, issuing them directly to designers, draughtsmen and foremen for use as working drawings and data sheets. (This plan is now followed by the Austrian, Dutch, Swedish and Swiss bodies.) The sale of sheets amounts to about 100,000 monthly.

From almost the first the Normenausschuss has been a periodical publication dealing with standardization. Formerly it was a separate publication, but now it forms a section of "Der Betrieb," a journal dealing with the general question of production and efficiency engineering. The communications from the Normenausschuss (Mitteilungen) average about 16 quarto pages per issue and form a separate section in this journal which appears semi-monthly, and has a circulation of 8000 copies.

The organization provides an extensive information service on standardization work in Germany and other countries, which is available to the industries as well as to their working committees. This is along much the same lines as the information service which has been started by the American Engineering Standards Committee. In this connection it is interesting to note that in general the German and Japanese industries appear to study foreign developments much more closely than do those of other countries.

Organization and Methods of Work

The organization and methods of work are similar to those in other countries. Next to the American Engineering Standards Committee, the German organization is the most decentralized of the national standardizing bodies. There is a Main Committee composed of representatives of the various national organizations supporting the movement, and a smaller Executive Committee. The detailed technical work of each project is in the hands of a working committee which in Anglo-Saxon countries would be called a "sectional committee" i.e., a committee made up of representatives of all bodies interested in the particular subject in hand.

Proposals for new subjects for standardization must come from some responsible body. The industry concerned is consulted, generally by a conference of the various organizations interested, to determine whether it is the consensus of opinion that the work should go forward. In case it is decided to undertake the work, the conference designates the chairman of the working committee.

The central office digests the information available on the subject for the use of the working committee. When agreement is reached in the committee on the draft of a standard it goes to the central office for editorial work. There it is scrutinized to see whether it is consistent with other standards; whether points have been included which concern other working committees; whether the drawings and nomenclature are in approved form, etc. After this editorial checking the central office has the draft of the standard put into proof form. It is then reviewed by an official clearing house committee, which contains a representative from each major line of work being carried on by working committees. If any change in substance has been made, it goes back to the working committee. If no such change has been made, it is published in the Mitteilungen, the official publication of the Normenausschuss, as a tentative proposal. Upon recommendation of the working committee, the standard is mailed to the members of the Executive Committee with a supporting statement. With their approval it is then republished as an official proposal. Six weeks are allowed for criticism, when a standard is finally published unless additional important criticisms are received.

Work in Special Industries

The foregoing refers to the work of the Central Body only, which is limited to subjects common to two or more industries. In addition there are some fifteen organizations known as special industry committees, each of which deals with the standardization work peculiar to a single industry, such as shipbuilding, electrical, agricultural, automotive, elevator, locomotive, paper, textile, and woodworking.

These committees are closely affiliated with, but not strictly an organic part of, the central body. They are organized not by the Normenausschuss, but by one or more technical or trade associations concerned with the particular subject in hand. Standards formulated by the special industry committees are published by the organization responsible. In most cases the final standards are published in loose-leaf form modeled closely after that of the standards issued by the Normenausschuss itself. These standards are submitted to the Normenausschuss before publication, in order to keep them consistent with the regular series of German industrial standards.

The volume of work being carried out through these special industry committees appears to be at least as great as that under the direct control of the Central Body.

Characteristics of Continental Work

Looked at broadly, and with exceptions such as must always be made in general statements of the kind, the Continental countries are going much further into dimensional standardization than has been done in Anglo-Saxon countries. This includes interchangeability of supplies and of machine elements, the interworking of parts and of related apparatus made by different makers, and the interchangeability, so far as the use is concerned, of complete machines and apparatus. By far the greater part of the work of the Normenausschuss is dimensional, greater attention being paid to such matters as machine elements, screw-threads, bolts and nuts, standard diameters, and systems of limit gaging. The Anglo-Saxon mind takes more to matters having to do with purchase and contract, such as specifications for materials, and for performance of apparatus, methods of test, etc. The Normenausschuss itself has done very little of this type of work as yet, but it has been highly developed by some of the German special industry committees, for

example, in the electrical industry. Some of these special industry committees are very active in the elimination of types, sizes and grades of manufactured products, and a special word has been introduced for this type of work, "Typung."

There is a greater dependence, on the Continent, upon theoretical and fundamental considerations, the Anglo-Saxon temperament giving rise to a much larger degree of expediency in adjusting commerical considerations in the process of arriving at agreements.

German manufacturers will go farther in yielding apparent temporary commerical advantages for the sake of advancing their national industry as a whole than is the case in America or Great Britain. Three principal reasons for this are: the great economic pressure under which German industry is laboring; the mental trait of more readily acquiescing in decisions affecting national welfare; and the belief that an essential to the rehabilitation of German industry is the rebuilding and great enlargement of their export trade, for which the importance of standardization on national lines is more readily apparent than it is in domestic trade.

The Germans have not yet had their standards translated into foreign languages for use in export, as the British are doing, but they are now giving consideration to this question.

German System of "Preferred Numbers"

As typical examples of the German work, their system of "preferred numbers" and their standard series of handles may be mentioned. The first is a fundamental piece of work, founded on theoretical considerations and of the first importance. It is a simple system of numbers for use in all new standardization work, in which gradated numerical values are required, such as standard gradated diameters of pulleys, thicknesses of plates, or capacities of machines. The Germans believe that its use is going to lead to great economies in material, in reducing the number of sizes, ranges, etc., simplify the carrying of stocks, facilitate interchangeability. It may be shown theoretically that, under average conditions, a given number of standard sizes laid out according to these numbers, will be better fitted to any series of jobs taken at random, than would be the same number of sizes laid out in any other way, and this with a minimum of material.

The standard handles furnish a typical example of German love of thoroughness of detail. There are two shapes, each adapted to a particular method of use, and there is a series of sizes for each shape. The profiles have been worked out with the most extreme care, an efficiency engineer having been employed to make time-motion studies to determine the exact profile that would insure the greatest accuracy in operaton with the minimum fatigue of the workman's hand. It is felt that by doing a thorough job once for all, different industries and firms will be saved from doing the same thing over and over, but always less well, and that at the same time interchangeability is introduced.

Industrial Significance

The standardization movement in Germany is particularly significant, since Germany is one of the three leading industrial countries. The industries of Austria, Holland, Sweden, and Switzerland, are so intimately related to those of Germany on account of geographical and other relationships that they are necessarily affected very largely by developments in Germany.

It appears that the work is being woven very intimately into the industrial fabric. The very large number of standards purchased by the industry, and the fact that the central organization has 5000 firms which are coöperating members, are a sufficient indication of this.

There seems to be a striking analogy between the present standardization movement in Germany, and the research movement developed there a generation ago. Whatever estimate one may place upon the role it played in German industries generally, everyone agrees that research was fundamental in the development of their great chemical industries. The role which the Germans are expecting standardization to play in all their industries would be not unlike the role which research has played in their chemical work.

A copy of a report on this subject, which was rendered to the American Engineering Standards Committee by its Secretary, will be sent upon request.

First Annual Report of the Federal Power Commission

Power developments of the past year, as shown in the first annual report of the Federal Power Commission, include a large number of projects on which, notwithstanding the industrial depression and the uncertain financial situation, construction work has already started, under license issued by the Commission, and indicate that the production and use of hydroelectric power in the United States is destined to be an outstanding industrial fact of the next twenty-five years.

Between 1910 and 1920 there was comparatively little waterpower development on the public domain or on navigable streams due to the fact that the legislation then on the statute books was, because of its limitations, considered unworkable. In the sixteen months following the passage of the Federal Water Power Act of 1920 there were filed with the Commission 185 applications for preliminary permit and 85 applications for license to develop waterpower, aggregating totals of 11,060,000 primary and 5,766,000 secondary horsepower or 16,826,000 horsepower of estimated installation. This is twice the water horsepower which has been developed in the United States to date and from five to six times greater than the aggregate of all applications filed with the Federal Government during the preceding 15 years.

Up to November 1, final action has been taken on 89 applications, in which 27 preliminary permits and 31 licenses were authorized, involving 1,415,600 primary and 2,627,000 installed horsepower. Construction is now under way on the following licensed projects.

	Primary horsepower	Installed horsepower
Henry Ford & Son, Inc., Hudson River, N. Y. . .	3,640	8,100
Niagara Falls Power Co., Niagara River, N. Y. . . .	341,500	572,230
Southern California Edison Co., Big Creek, Cal. . .	165,000	546,000
Alabama Power Co., Coosa River, Ala.	21,760	110,000
Snow Mountain Power & Water Co., Eel River, Cal.	9,500	16,670
Western States Gas & Electric Co., American River, Cal.	6,400	6,400
Wisconsin-Minnesota Light & Power Co., Chippewa River, Wis. . . . . (Preliminary construction only)	10,000	20,000
Total.	557,800	1,279,400

Much time and care has been devoted during the year to compilation of the rules and regulations governing administration of the Federal Water Power Act. The Commission's serious need at present is for Congressional authorization permitting the use of its appropriations in employment of personnel sufficient to make up a small organization of trained and experienced men capable of meeting intelligently the important and perplexing engineering and economic problems which are constantly arising and upon the correct solution of which will depend the value of Federal legislation and, in no small degree, the future of the electric-power industry.

A.S.M.E. Transactions Index to be Published

For the past forty-three years valuable information has been accumulating in the Transactions of The American Society of Mechanical Engineers. The Publication Committe now plan to render this material available by the publication of an index which will include the first forty-two volumes. The index, however, will be published solely on a subscription basis and those who desire to have this valuable means of reaching the important information included in the A.S.M.E. Transactions should write at once to the Secretary indicating their desire to have a copy printed for them. The book will be bound in morocco to conform to the edition of Transactions. The exact price will depend upon the number ordered and announcement of it will be made upon the closing of the subscription list. This offer will be announced only through the columns of Mechanical Engineering and the *A.S. M.E. News*. An order card will be included in volume forty-two of Transactions which will be mailed to the membership early in March. The subscription list will be closed on April 15 and if the number of orders is sufficient, work will be started at once on the preparation of the book.

NEWS OF OTHER SOCIETIES

American Institute of Chemical Engineers

The fourteenth annual meeting of the American Institute of Chemical Engineers, held at Baltimore, Md., Dec. 6–9, 1921, was devoted primarily to the subject of gas warfare and chemical preparedness. A symposium on chemical engineering and national defense, continued from the first to the third day of the convention, was opened by an address by President David Wesson and included papers pointing out the humane aspects of gas warfare and reviewing the capacity for the production of chlorine in the United States, its uses, storage, and transportation.

At other sessions of the convention a survey of the lime industry was presented; Professor Cavalier, of France, exchange professor at Johns Hopkins University, read a paper on the Development of the Chemical Laboratories in France; glass as a material for chemical use was discussed; and the difficulties encountered in attempting to utilize low pressure steam after compression in evaporators were pointed out.

At a joint meeting with the Maryland Section of the American Chemical Society at Johns Hopkins University, a paper dealing with the development of a catalyzer by means of which carbon monoxide can be oxidized at room temperature to carbon dioxide was presented, and applications of ultra violet light described.

A number of excursions were held during the meeting, the most popular of which was an all-day visit to Edgewood Arsenal, where the entire morning was spent in inspection of the large installations of Nelson chlorine and caustic cells, the multiple effect evaporators, the gas-mask factory and the extensive research laboratories.

In the afternoon there was a field demonstration of various forms of gas warfare. In connection with the inspection of the Arsenal an address on chemical warfare was delivered by Brig-Gen. Amos A. Fries.

At the business meeting on the first day of the convention the council of the Institute reported an amendment to the constitution providing for student chapters similar to those affiliated with other engineering societies and another resolution providing for the organization of local sections of the Institute.

Arthur D. Little, as chairman of the Committee on Chemical Engineering Education, presented a study of the courses in chemical engineering offered at all the technical schools and universities of the United States and it was voted to call a meeting of representatives of institutions offering courses in chemical engineering for the purpose of securing greater uniformity in such courses.

L. W. Wallace, executive secretary of the F.A.E.S., addressed the business session on the most important activities of the Federation, of which the Institute is a member society.

American Society of Refrigerating Engineers

The three-day annual meeting of The American Society of Refrigerating Engineers, held in New York, Dec. 5–7, 1921, included six technical sessions. At the first of these the subjects considered were the artificial production of natural ice, the use of automatic temperature-controlled expansion valves, and small insulated containers, the speakers on these respective subjects being R. H. Hemphill, Charleston, S. C., G. A. Wegner, Rochester, N. Y., and M. E. Pennington, New York, N. Y.

In three papers presented at an evening session on December 5, C. S. Cragoe, of the U. S. Bureau of Standards, outlined the present status of the measurements of superheated ammonia at the Bureau, and discussed specific volumes of superheated ammonia vapor and of ethyl chloride, liquid and vapor. G. F. O'Conner, also of the Bureau, was co-author with Mr. Cragoe of the last paper. It was announced that the Bureau of Standards would soon be in a position to issue tables on superheated ammonia. A paper entitled Coördinating Technical Knowledge and Practical Conditions in Refrigerating Plants, by Peter Neff, Canton, Ohio, was also presented at this session.

Ammonia compression was the main topic at the two sessions held on December 6. The construction and operation of three types of compressors were described by F. L. Fairbanks, of Boston. These types were a slow-speed steam-driven compressor with a booster set, a motor-driven compound compressor and a uniflow steam-engine-driven compound compressor with feather valves. George A. Horne, New York City, spoke on the subject of compound ammonia compression, describing one of the most complete tests for a compound compressor which had even been conducted. Synchronous and starterless induction motors for ammonia compressors were discussed, and a paper on cooling systems of buildings presented.

Among the papers presented at the session on the closing day of the meeting was one by H. J. Macintire, of Urbana, Ill., dealing with research work in refrigeration conducted at the University of Illinois; the presentation of a total-heat diagram for carbon dioxide, showing the effect of pressure, also by Mr. Macintire; a description of a new thermal testing plate for conduction and surface transmission, by A. J. Wood, State College, Pa.; and a discussion of the theory and practice of spray nozzle cooling, by B. H. Coffey and G. S. Dauphinee, both of New York City.

An excursion to the North Moore Street Power Plant of the Merchants Refrigerating Co. of New York was held on the second day of the convention.

Items of business at the opening session included a discussion of the Mechanical Refrigeration Safety Code.

American Petroleum Institute

The American Petroleum Institute held its second annual meeting in Chicago, Ill., December 6–8, 1921. In his opening address, Thomas A. O'Donnell, president of the Institute, referring to the adequacy of the world's supply of petroleum, gave as his opinion that if unrestricted opportunity for development is afforded to those engaged in the industry, the supply of petroleum products will be adequate for all requirements for many generations to come.

Walter C. Teagle, president of the Standard Oil Company of New Jersey, believed that in adequate storage facilities lies the chief requisite for securing a better balance between production and consumption of petroleum products and the resulting avoidance of the serious price fluctuations which the industry has seen during the current year.

The technical sessions of the Institute were devoted almost exclusively to a discussion of the automotive fuel problem. Dr. Van H. Manning, director of research of the Institute, presented a quantitative survey of the petroleum industry from the standpoint of motor fuel, and Edward S. Jordan, president of the Jordan Motor Car Company, a similar survey of the automotive industry. These speakers pointed out the effect of automotive fuel requirements on the petroleum industry and upon the future development of motor cars.

N. A. C. Smith, petroleum chemist, of the Bureau of Mines, discussed the volatility of motor fuel as marketed in the United States, and stated that he believed that eventually we would have as nearly uniform gasoline as is commercially possible.

The motor fuel problem from the standpoint of the automotive engineer was discussed by O. C. Berry, chief of the Wheeler-Schebler Carburetor Company, who stated that the present grade of fuel can be used with fair success in the laboratory and urged that refiners make no further reduction in volatility until the automotive industry is prepared to meet it.

F. C. Mock, research engineer, Stromberg Motor Devices Company, discussing the effect on motor economy of volatility changes in the fuel, urged as great a uniformity as possible in motor fuel, and the adoption of a recognized standard to which motor fuels should conform.

Greater uniformity in motor fuel was the chief point brought out in all the discussions. The adoption of uniform specifications was urged and some speakers suggested the appointment or establishing of a referee laboratory to which all fuel questions arising between automotive engineers and refiners could be referred.

National Society for Vocational Education

The National Society for Vocational Education, which as the National Society for the Promotion of Industrial Education, was the "first national organization to promote interest in publicly supported vocational education," held its fifteenth annual convention in Kansas City, Mo., Jan. 5, 6, and 7, 1922.

The larger part of the program was given over to sectional meetings on various phases of vocational education. These covered agricultural, commercial, home-making, and industrial education,

part-time and continuation schools, teacher training, training in industry, and industrial rehabilitation.

The work being done by other national associations engaged in vocational education was told by representatives of such organizations at one of the general meetings.

A joint meeting of the Industrial Education Section and the Training in Industry Section considered the subject of cooperation between public and private training agencies, the present situation was outlined, its causes discussed, and ways and means of dealing with it suggested.

Other sessions of the Industrial Education Section gave special attention to the day industrial and trade schools, and their relation to industry.

Problems of the part-time and continuation schools were studied at several sessions and their value as economic, industrial and social factors brought out. What is being done in industrial rehabilitation formed the topic of several sessions.

Among educational exhibits at the convention, of interest to all and of special value to teachers and supervisors in vocational work, were those showing building plans for vocational schools, vocational education material not published in book form, and the use of motion pictures in teaching shop precesses.

LIBRARY NOTES AND BOOK REVIEWS

Library Book Loans

The Library Board has adopted rules authorizing the Director of the Library to lend to members of any Founder Society any duplicate books in the Library, subject to the following four rules:

1 Duplicate books may be lent to members of Founder Societies or of any other societies that contribute to maintain the Library

2 Books will be lent for twenty-eight days, including time in transit

3 Five cents a day will be charged for each book kept longer than twenty-eight days

4 Borrowers shall be responsible for books borrowed, and shall pay shipping and insurance charges from and to the Library.

The Library has several thousand volumes that can be lent under this authorization. These include a considerable number of textbooks, reports, etc., of various dates. Periodicals are not included, as the cost of storing duplicate sets seems prohibitive and individual articles can be photoprinted at little expense. The collection is being increased regularly by the addition of any suitable duplicates received by the Library. Members are invited to present any books of permanent value for this purpose, which they can spare from their libraries. It is hoped that the collection may in time become adequate to meet the usual needs of members by providing any standard book needed for a short time.

No catalog has been published, although it is hoped that one may be, when the collection becomes extensive enough to warrant doing so. Until that time, the Director will be glad to receive requests and report as to whether the books are available or not.

The A.S.M.E. Issues Westinghouse Biography

The subscription edition of the Life of George Westinghouse was mailed early in January and the popular edition, published by Charles Scribner's Sons, was placed on sale on January 27. The subscription edition, which was sold to members of the American Society of Civil Engineers, American Institute of Mining and Metallurgical Engineers, The American Society of Mechanical Engineers and the American Institute of Electrical Engineers, appeared in two bindings, the half morocco and the buckram. This edition, in contents and form, is a worthy addition to the publications of the A.S.M.E.

Through the courtesy of some friends of Mr. Westinghouse, the plates for the book have been placed at the disposal of the Society, and, with the coöperation of Charles Scribner's Sons, a plan is being developed whereby the popular edition can be widely distributed.

The book is already attracting wide interest as a story of the life of a man preëminent among engineers.

The author of the book, Colonel Henry G. Prout, was an intimate friend of Mr. Westinghouse and in its fascinating record of a remarkable life, he has developed a great amount of material which is of value, not only in connection with the life of George Westinghouse, but as an inspiring revelation of the part the engineer must play in our present day civilization. A more complete review will appear in this section of the March issue of Mechanical Engineering.

Automobile and Aircraft Engines. By Arthur W. Judge. Sir Isaac Pitman & Sons, Ltd., London and New York, 1921. Cloth, 6 × 8 in., 642 pp., illus., tables, $9.50.

Presents, in as concise and elementary form as possible, an account of the theory of the lighter-fuel type of high-speed internal-combustion engine, and of the experimental results obtained from it. Intended especially for engineers and designers of automotive machinery. Nearly twice the size of its predecessor, the additions being chiefly experimental data obtained in recent years.

Automobile Engineering. Chicago, American Technical Society, 1920. 6 vols. Fabrikoid, 6×8 in., illus., $29.80.

A course of self-instruction and a book of reference covering the maintenance and operation of automobiles of all kinds. Information given is presented clearly and without mathematics, and is illustrated by many cuts and drawings. Earlier editions were entitled Cyclopedia of Automobile Engineering.

Cane Sugar. By Noel Deerr. Second edition. Norman Rodger, London, 1921. Cloth, 7×10 in., 644 pp., plates, illus., 42s.

The author of this work, writing from long experience in the cane-sugar industry, acquired in the more important sugar-producing districts of the world, gives an account of the salient points of the industry, with a detailed treatment of its more important aspects. The botany, agriculture and pathology of the sugar cane, sugar-house practice and the control of the processes are given careful treatment. Many colored plates are included, and there are numerous lists of references and an extensive bibliography. This edition has been reset and enlarged.

Compteurs de Vapeurs. By E. Hoehn. Ch. Béranger, Paris, 1921. Paper, 6×9 in., 34 pp., illus., 2 fr.

This pamphlet by the chief engineer of the Swiss association of boiler owners describes the theory and operation of ordinary and recording steam meters, with notes on the advantages and disadvantages of the different types.

Cours de Mecanique Rationelle. By Louis Roy. Gauthier-Villars et Cie, Paris, 1921. Paper, 5×10 in., 259 pp.

This volume, with the author's previous book on graphic statics and strength of materials, forms a course of instruction in mechanics for students of engineering. The present work is intended for beginners and therefore is confined to the elements of mechanics, which it presents so that students will have the grounding necessary for the study of applied mechanics, general physics and electrical engineering.

Economics of Petroleum. By Joseph E. Pogue. John Wiley & Sons, Inc., N. Y., 1921. Cloth, 6×9 in., 375 pp., plates, illus., $6.00.

The purpose of this book is to present the more important economic facts relating to petroleum, to interpret the changes that are taking place in the industry and to forecast the future trend of these changes. The book is intended for those engaged in the petroleum industry as engineers or producers, and for those engaged in industries dependent on petroleum products, and contains useful information on our resources, the trend of development, production and refining, transportation, prices, trend of consumption, and similar topics.

Die Steuerungen der Dampfmaschinen. By Heinrich Dubbel. Second edition. Julius Springer, Berlin, 1921. Cloth, 6 × 9 in., 384 pp., illus., 69 marks.

This is a treatise on the theory and design of valve and reversing gears for reciprocating steam engines, for the use of designers. The discussion is confined chiefly to the modern forms that have been introduced to meet the demands of high steam pressures and increased speeds, and the competition of steam turbines and gas engines. Matter which is only of historical interest has been omitted, but full attention is given to gearing of the types which have proved best fitted to modern requirements. The discussion of reversing gears includes material on locomotives, rolling-mill and hoisting engines.

Invention the Master-Key to Progress. By Bradley A. Fiske. Dutton & Co., New York, 1921. Cloth, 6 × 8 in., 356 pp., illus., $4.

The thesis of this author is that invention, acting through literature, science, art, war and the other activities of men, has initiated all creative human progress; and his book is an interesting account of what inventors have accomplished through the ages, and a forecast of what may be done in the future, if the art of invention is properly fostered.

Machine Drawing. By Carl L. Svensen. D. Van Nostrand Co., New York, 1921. Cloth, 6 × 9 in., 214 pp., illus., $2.25.

This textbook is written for students who have had previous instruction in mechanical drawing and is intended to develop an understanding of the relation of machine drawing to engineering. It includes a complete treatment of working drawings, drafting-room practice, a chapter on the principles and practice of dimensioning, a study of the common machine details, jigs and fixtures, and a large collection of problems.

Material Handling Cyclopedia. Compiled and edited by Roy V. Wright, John G. Little and Robert C. Augur. Simmons-Boardman Publishing Co., N. Y., 1921. Cloth, 9×12 in., 846 pp., illus., $10.

Designed to present comprehensively definitions, descriptions, illustrations, applications and methods of operation of industrial devices for handling materials. Covers hoisting machinery, package conveyors, loose-material conveyors, elevators, trackless transportation, industrial rail transportation and handling systems. Each section has been prepared by a specialist.

Mechanical Handling of Goods. By C. H. Woodfield. Sir Isaac Pitman & Sons, Ltd., London, 1921. (Technical primers.) Cloth, 4 × 6 in., 116 pp., illus., $0.85.

The object of this book is to set forth sufficient information upon the handling of goods and material to enable the uninitiated to understand the methods and equipment employed and appreciate the economic possibilities of dealing with goods by mechanical methods.

Mechanical Principles of the Aeroplane. By S. Brodetsky. The Macmillan Co., New York, 1921. Cloth, 6 × 10 in., 272 pp., illus., $7.

Section one, Motion in Air, contains a brief statement of the general theory of resisted motion, a discussion of the dynamics of a body moving in air and the theory of steady flight, which indicates what it is that aerodynamical research must investigate. In section two, Dynamics of Air, the hydrodynamical method of attacking the problem is set forth, and in section three, Aeroplane Motion, theoretical and experimental results are applied to the steady flight and stability of aeroplanes, followed by an account of the motion of a disturbed aeroplane. The treatment is confined to the mathematical parts of these problems.

Memoires Sur L'Electromagnetisme et L'Electrodynamique. By André-Marie Ampere. Paper, 4 × 7 in., 110 pp., illus., 3 fr.

The two classic memoirs in this little book are that in which Ampère described his experiments upon the action exerted on an electric current by another current or a magnet, and the one giving the results of his study of the formula expressing the attraction and repulsion between two infinitely small elements of two conductors. They are here reprinted from the best text, in attractive form.

La Physique Theorique Nouvelle. By Julien Pacotte. Gauthier-Villars et Cie, Paris, 1921. Paper, 182 pp., 6 × 10 in., 12 fr.

The new physics in question had its origin in Lorentz's electrodynamics, which is the definitive form of Maxwell's theory; its most advanced theories are due to Einstein; it has to do with relativity, with the energy equivalent of two masses of matter, with atoms of energy. The author presents a historical, critical, non-mathematical account of the theories that underlie modern ideas, suitable as an introduction to the subject.

Practical Least Squares. By Ora Miner Leland. First edition. McGraw-Hill Book Co., Inc., New York, 1921. Cloth, 6 × 9 in., 237 pp., $3.00.

This textbook is based on the course given to students of civil engineering at Cornell University and is designed particularly for use in short courses of instruction and by engineers and scientists in connection with their private practice. It will not replace more elaborate treatises, but the author hopes it will introduce the student directly to the simpler methods of solving the ordinary problems in adjustment.

Power's Practical Refrigeration. Compiled by the editorial staff of *Power*. First edition. McGraw-Hill Book Co., Inc., New York, 1921. Fabrikoid, 6 × 8 in., 283 pp., illus., tables, $2.

A volume dealing with the practice of refrigeration, but also including the laws governing its production. Chiefly made up of articles that have appeared in *Power* and have proven of particular value to those operating refrigerating plants.

Profit Sharing by American Employers. A report of the Profit Sharing Department of the National Civic Federation. Dutton & Co., New York, 1921 Cloth, 5 × 8 in., 416 pp., $8.

The first edition of this book, published in 1916 by The National Civic Federation, was based on analyses of more than two hundred plans for profit-sharing in use in this country. It was intended to present testimony, from managers of manufacturing establishments, concerning the success and failure of such plans. This edition is practically a new book, as much of the former material has been omitted and numerous additions have been made, enlarging the book and bringing it up to 1919.

The Psychology of Industry. By James Drever. Dutton & Co., New York, 1921. Cloth, 5 × 8 in., 148 pp., $2.50.

Dr. Drever discusses such topics as the intelligence and vocational fitness of the worker, scientific mental engineering, the factors determining efficiency of work, fatigue, economy of movement, advertising and salesmanship. Upon these and similar matters he sets forth what has been done by the psychologist, in language understandable by the ordinary man. A special effort is made to adhere to the psychological point of view and to emphasize principles rather than details of results.

Radio Questions and Answers. By Arthur R. Nilson. First edition. McGraw-Hill Book Co., Inc., New York, 1921. Boards, 5 × 7 in., 86 pp., illus., $1.

A quiz compend for those preparing for examination. Treats of theory, apparatus, laws and regulations, etc.

Railroad Shop Practice. By Frank A. Stanley. First edition. McGraw-Hill Book Co., Inc., New York, 1921. Cloth, 6 × 9 in., 331 pp., illus., $4.

The purpose of this book is to show typical methods and appliances as adapted to the work of various railroad repair shops, large, medium and small, situated in different parts of the United States. Much of the material presented has been taken from the articles by the author and others in technical journals, but a considerable amount is new.

Railway-Signaling. By Everett Edgar King. First edition. McGraw-Hill Book Co., Inc., New York, 1921. Cloth, 6 × 9 in., 371 pp., illus., diagrams, $4.

The purpose of this book is to collect what is already in common practice in railway signaling and to present it in text-book form, suitable for use by those beginning the study of this subject. The volume discusses signal indications, interlocking, block signaling, signal mechanisms and highway-crossing signals.

Steam Boilers. By Terrell Croft. First edition. McGraw-Hill Book Co., Inc., New York, 1921. Cloth, 6 × 8 in., 412 pp., illus. $4.

This book has been compiled for men of little schooling who wish to inform themselves about the construction and operation of steam boilers, especially those preparing for examinations for engineers' licenses. It treats of the functions, history and modern types of boilers, boiler construction, accessories, steam generation, superheating, fuels, settings, furnaces, feedwaters, boiler-room equipment, inspection and management, in clear, simple and easily read language.

Steam-Engine Valves and Valve Gears By E. L. Ahrons. Sir Issac Pitman & Sons, Ltd., London, 1921 (Technical primers.) Cloth 4 × 6 in., 112 pp., illus., $0.85.

This primer gives, in an elementary form, a concise description of the usual forms of steam-engine valves and valve gears, and an explanation of their action.

Temperature Indicating and Controlling Systems. By Franklin D. Jones. First edition. Industrial Press, New York, 1921. Paper, 6 × 9 in., 59 pp., illus., $0.50.

A general review of the application of thermoelectric pyrometers to the heat-treatment of steel parts. The methods and apparatus used in various plants to indicate, control and record temperature are described and illustrated.

Theorie und Wirklichkeit bei Triebwerken und Bremsen. By St. Löffler. R. Oldenbourg, München und Berlin, 1919. Paper, 6 × 9 in., 94 pp., 5.50 M.

This small volume contains the author's answers to various criticisms of the theory advanced by him in his earlier volume entitled Mechanische Triebwerke und Bremsen. The various objections to the author's former assertions are met and answered in detail.

Thermodynamics. By J. E. Emsweiler. First edition. McGraw-Hill Book Co., Inc., New York, 1921. Cloth, 6 × 9 in., 266 pp., diagrams, $3.

An attempt to present the subject progressively so that the reader may easily recognize the relation of each new demonstration to the whole. For this purpose the order of presentation is changed from that usually employed. Steam is placed first, followed by vapor refrigeration, after which the permanent gases, mixtures and air-heat engines are studied. Formal discussion of the laws of thermodynamics and the kinetic theory of gases is postponed until the close of the book

Der 1000 PS Flugmotor. By Edmund Rumpler. R. Oldenbourg, München, 1921. Cloth, 10 × 21 in., 63 pp., plates, 50 M.

Present-day aviation engines are, according to this monograph, only lighter automobile engines, constructed in almost every case by automobile engineers without special knowledge of the problems of flight. The engine here described is designed to meet the peculiar conditions of flight and overcome the deficiencies of the engines hitherto used. The text and drawings illustrate a 1000-hp. engine, a combination of the radial and horizontal arrangement of cylinders, having four sets of seven radial cylinders.

Tidal Power. By A. M. A. Struben. Sir Isaac Pitman & Sons, Ltd., London, 1921. Boards, 4 × 6 in., 115 pp., diagrams, $0.85.

This little book is intended to stimulate interest in a field that is likely to attract attention in the near future. It indicates some of the possibilities, the difficulties that are found and the systems that have been proposed.

Time Study and Job Analysis. By William O. Lichtner. Ronald Press Co., New York, 1921. Cloth, 6 × 9 in., 397 pp., illus., $6.

The author attempts to explain the practical application of these methods in simple, non-technical terms, as might be done in a series of conferences with an executive charged with the responsibility of decision. The book first presents a general review of the principles of job standardization and their application to time study and job analysis. The organization of a staff to carry out the work is then described in detail. This is followed by a detailed description of the technique of the subject, and the book closes with a consideration of the relation of job standardization to industrial problems.

Traité de Balistique Extérieure. By P. Charbonnier. Volume I. Gauthier-Villars et Cie, Paris, 1921. Paper, 6 × 10 in., 637 pp., diagrams, 7 francs.

This is the first of the six volumes in which it is proposed to publish Charbonnier's treatise on external ballistics to which the Poncelet prize was awarded by the French Institute in 1919. The author has planned a treatise, embracing everything relating to the science, methodically classified and treated in detail, suited to the needs of students of its theory and of practical artillerymen. His book therefore is a summary of our knowledge at the close of the great war.

The present volume, intended as an introduction to the subject, is divided into two parts. The first is a discussion of the three limiting cases of the ballistic problem, motion in a vacuum and rectilinear motion and vertical motion in a resisting medium. The second considers the general theorems of ballistics, and includes the general properties of atmospheric trajectories and the application of analysis to the ballistic problem.

Turbines. By A. E. Tompkins. Third edition, revised. The Macmillan Co., New York, 1921. Cloth, 5 × 8 in., 180 pp., illus., $2.50.

Describes, in simple, non-mathematical fashion, good modern practice in the construction and working arrangement of water turbines, turbine pumps and steam turbines. The book will be useful to students and to men engaged in fitting and repairing turbines.

Union Engineering Handbook; Pumping Machinery, Air Compressors, Condensers. Compiled by E. P. Ordway. First edition. Union Steam Pump Co., Battle Creek, Mich., 1921. Cloth, 5 × 9 in., 442 pp., illus., $2.

Intended for engineers, architects and others interested in air compressors, condensers and steam, centrifugal, power and vacuum pumps. Contains the engineering information and data usually desired in calculating the problems encountered in handling these machines, with special information on the products of the company which publishes the book.

Vorrichtungen im Maschinenbau nebst Anwendungsbeispielen. By Otto Lich. Julius Springer, Berlin, 1921. Cloth, 6 × 9 in., 507 pp., illus., diagrams, 120 m.

A detailed study of clamps, fixtures and jigs for machine tools and of their application to increase output. All the customary operations, boring, slotting, planing, milling, forging, hardening, etc., are considered. There is also a section on the savings obtainable by such attachments and one on maintenance and repair. The book is intended for machine builders, and for operators who wish to increase the efficiency of existing equipment. The author presents his book as a contribution toward the reconstruction of the German metal industries, which he believes will be possible only through the greatest possible economy of time and of labor.

The Working of Steel. By Fred H. Colvin and K. A. Juthe. First edition. McGraw-Hill Book Co., Inc., New York, 1921. Cloth, 6 × 9 in., 245 pp., illus., $4.

The authors have collected, from their own experience and that of others, information upon the most approved methods of working the various kinds of steel in use today. These include low-carbon, high-carbon and alloy steels of various kinds and from a variety of industries. The book discusses the chemical and physical properties of steels, forging, annealing, case-hardening, heat treatment and hardening.

Index to Volume 43 of Mechanical Engineering

An index to Volume 43 of Mechanical Engineering is now in the course of preparation, and, it is expected, will be issued the latter part of February. A copy of this index will be sent to each member of the Society or subscriber who sends in a written request therefore. In order that no more copies than are necessary to supply the demand may be printed, requests for copies should be received at headquarters not later than February 15.

THE ENGINEERING INDEX

(Registered U. S. Patent Office and Canadian Patent Office.)

THE ENGINEERING INDEX presents each month, in conveniently classified form, items descriptive of the articles appearing in the current issues of the world's engineering and scientific press of particular interest to mechanical engineers. At the end of the year the monthly installments are combined along with items dealing with civil, electrical, mining and other branches of engineering, and published in book form, this annual volume having regularly appeared since 1906. In the preparation of the Index by the engineering staff of The American Society of Mechanical Engineers some 1200 technical publications received by the Engineering Societies Library (New York) are regularly reviewed, thus bringing the great resources of that library to the entire engineering profession.

Photostatic copies (white printing on a black background) of any of the articles listed in the Index may be obtained at a price of 25 cents per page, plus postage. A separate print is required for each page of the larger periodicals, but wherever possible two small or medium-sized pages will be photographed together on the same print. The bill will be mailed with the print. When ordering photostats identify the article by quoting from the Index item: (1) Title of article; (2) Name of periodical in which it appeared; (3) Volume, number, and date of publication of periodical; (4) Page numbers. Orders should be sent to the Engineering Societies Library, 29 West 39th Street, New York.

ACCOUNTING

Power Plants. Power-Plant Accounts, Wilfred A. Miller. Power, vol. 54, nos. 16, 17, 18, 19, 20, 21, 22, 23, 24 and 25, Oct. 18, 25, Nov. 1, 8, 15, 22, 29, Dec. 6, 13 and 20, 1921, pp. 596–599, 636–638, 680–684, 719–723, 769–772, 805–809, 848–852, 891–894, 934–936 and 979–980, 59 figs. Oct. 18: How to record indirect expenses. Oct. 25: Interest on borrowed money, profit and related subjects. Nov. 1: Considerations in buying equipment; meaning of depreciation. Nov. 8: Power plant as manufacturing department. Nov. 15: "Income" and "profit and loss" accounts. Nov. 22: The "surplus" account. Nov. 29: Debit and credit; the cash account. Dec. 6: Closing ledger accounts. Dec. 13: Investment account and reserve for depreciation and obsolescence. Dec. 25: Scrapping equipment. (Continuation of serial.)

AERODYNAMICS

Standardization. Standardization and Aerodynamics, L. Prandtl. Aerial Age Weekly, vol. 14, no. 4, Oct. 3, 1921, pp. 79–80. Discusses wind tunnels, size of models and air velocity, placing of models, drift coefficients and the results.

AIR

Joule-Thomson Effect. The Joule-Thomson Effect for Air, Frederick G. Keyes. Jl. Am. Chem. Soc., vol. 43, no. 7, July 1921, pp. 1452–1470, 2 figs. Discusses Hoxton's investigation; expansion coefficients of a gas; absolute ice-point temperature; Joly constant-volume specific-heat values for air.

AIR COMPRESSORS

Combination Hoist and. New Combination Hoist and Air Compressor. Eng. & Contracting, vol. 46, no. 21, Nov. 23, 1921, p. 483, 1 fig. Designed especially for bridge and elevated-tank erection, and brought out by Novo Engine Co., Lansing, Mich. Can also be used for trench work.

German. Air Compressors and German Aviation (Les compresseurs d'air dans l'aviation Allemande), G. Lehr. La Technique Moderne, vol. 13, no. 9, Sept. 1921, pp. 369–376, 11 figs. Discusses compressors by Schwade, Brown-Boveri, A. E. G., Siemens-Schueckert; also control systems of air supply for combustion.

Regulation. The Regulation of Air Compressors. Power, vol. 54, no. 24, Dec. 13, 1921, pp. 918–921, 11 figs. Discusses various arrangements used to control amount of air delivered by compressor.

AIR CONDITIONING

Chemical Processes. Notes on the Relation of Atmospheric Conditions to Chemical Processes, A. E. Stacey. Jl. Am. Soc. Heating & Ventilating Engrs., vol. 27, no. 8, Nov. 1921, pp. 777–781, 3 figs. Gives a few typical examples of need of air conditioning in chemical industry.

AIRPLANE ENGINES

Bristol Jupiter. Tests of the 450 Hp. Bristol Jupiter Engine. Aviation, vol. 11, no. 24, Dec. 12, 1921, pp. 685–686, 2 figs. An air-cooled radial aero engine, which has passed the tests of the British Air Ministry.

Carburetors. See CARBURETORS.

Cylinders. Preliminary Calculation of Cylinder Dimensions for Aircraft Engines, Otto Schwager. Aerial Age Weekly, vol. 14, no. 8, Oct. 31, 1921, pp. 179–180 and 187. Method described depends on air requirement of fuel. Gives examples for water-cooled, air-cooled and rotary engines. Translated from Zeit. fur F. & M., Dec. 31, 1920.

Fuel. The Problem of Fuel for Aviation Engines, Aerial Age Weekly, vol. 14, no. 1, Sept. 12, 1921, pp. 8–11 and 22–23, 6 figs. Technical note of Nat. Advisory Committee for Aeronautics. Discusses composition, quantity available, price per heat unit, stocks of fuel at aerial ports, preparation of fuel mixtures, carburetor function, etc. Lecture given by Prof. Kutzbach.

Fuel Pump. The Sylphon Fuel Pump for Liberty "12" and Wright Model "H" Engines. Air Service Information Circular, vol. 3, no. 281, Oct. 15, 1921, 8 pp., 4 figs. Designed to fill need for an engine-driven fuel pump in order to obviate use of air pressure where sufficient gravity head is not available. Description and rules for dissembly.

Gear Pump. Performance of a Vane-Driven Gear Pump, R. H. Heald. Aerial Age, vol. 14, no. 4, Oct. 3, 1921, pp. 81–83 and 90, 8 figs. Gives results of tests with pumping unit driven by a wind wheel in air stream during flight, for pumping gasoline to tank in upper wing from which it flows by gravity.

Radiators. Cooling System Test of the Curtiss JN-6 with Packard 1A-744 Engine Equipped with Side Radiators. Air Service Information Circular, vol. 3, no. 294, Oct. 20, 1921, 12 pp. 8 figs. Result of test to determine effectiveness of side radiators.

Getting Airplane Details on a Manufacturing Basis. Am. Mach., vol. 55, no. 22, Dec. 1, 1921, pp. 886–887, 7 figs. Economical methods in radiator construction. Soldering tube ends in multiple. Punches and dies for fittings made adjustable by insertion of loose pieces.

AIRPLANE PROPELLERS

Tandem. The Question of Tandem Propellers, A. Lapresle. Aviation, vol. 11, no. 24, Dec. 12, 1921, pp. 679–680, 3 figs. Gives results of experiments carried out by Eiffel; tandem propellers must turn in opposite directions if the rear propeller is to have a satisfactory efficiency. Translated from L'Aerophile.

AIRPLANES

Aerofoils. The Influence of Aerofoil Dimensions on Speed (Ueber den Einfluss der Flügelabmessungen auf die Fluggeschwindigkeit), E. Lupberger. Zeit. für Flugtechnik u. Motorluftschiffahrt, vol. 12, no. 21, Nov. 15, 1921, pp. 316–318, 2 figs. Concludes that all efforts to increase difference between flying and landing speed by changing surface dimensions or by use of divided planes have little prospect of practical success.

Blériot Passenger. The New Blériot-Aeronautique Airplanes (Les nouveaux avions de "Blériot-Aeronautique"). L'Aeronautique, vol. 3, no. 30, Nov. 1921, pp. 436–437, 5 figs. Describes Spad 34, 38 and 45, the latter transporting 17 passengers and crew of 3 and having four 275-hp. Hispano-Swiss engines, marine type.

Brakes. Electro-Magnetic Brakes for Aeroplanes. Aerial Age Weekly, vol. 14, no. 3, Sept. 26, 1921, pp. 57 and 54. Describes the Gernsback device, an electromagnetic attracter on the landing stage which brings airplane to a stop at a definite point and within short range. From "Sea, Land and Air."

Commercial. The Barnhart Twin No. 15 "Wampus-Kat." Aerial Age Weekly, vol. 13, no. 26, Sept. 5, 1921, pp. 615–617, 4 figs. Commercial airplane built by C. R. Little Aircraft Works, Pasadena, Cal. Report of test pilot; describes principal features and gives specifications.

Curtiss Navy Racer. The Navy Racer Which Won the Pulitzer Trophy, Herbert Chase. Automotive Industries, vol. 45, no. 21, Nov. 24, 1921, pp. 1015–1016, 2 figs. Designed and built complete in Curtiss plant. Gives specifications and equipment; average speed attained 176.7 m.p.h.; 12-cylinder V-type engine; 405 b.hp. at 2,000 r.p.m.

DH-4 Corps Observation. Performance Test of DH-4 with 400 Hp. Liberty "12" Engine, Equipped as Two-Seater Corps Observation Airplane. Air Service Information Circular, vol. 3, no. 287, Oct. 1, 1921, 7 pp., 5 figs. Summary of test results; distribution of weights; description of airplane and power plant.

Fokker Monoplane. A Dutch Passenger-Carrying Monoplane, P. M. Heldt. Automotive Industries, vol. 45, no. 23, Dec. 8, 1921, pp. 1113–1114, 2 figs. Describes a Fokker carrying six passengers and fuel for 500 miles; 200-hp. B.M.W. engine.

Official Performance Test of Fokker Monoplane D-VIII Equipped with 110 Hp. Oberursel Engine. Air Service Information Circular, vol. 3, no. 288, Oct. 1, 1921, 8 pp., 5 figs. Gives summary of results of test, pilot's observations, and description of airplane and power plant.

Improving Performance. Means for Improving Airplane Performance, Harlan D. Fowler. Aviation, vol. 11, no. 23, Dec. 5, 1921, pp. 652–655, 14 figs. Discusses aerofoils, combining high speed with large load, variable area, etc.

Load Factors. Effect of Variation in Load Factor on Structural Weight of Wings, R. A. Miller. Aerial Age Weekly, vol. 14, no. 8, Oct. 31, 1921, pp. 177–178, 1 fig. Concludes that area of spars varies directly with load factor, area of struts varies with load factor and increases at slightly smaller rate than load factor, etc.

Martin Bomber. Official Performance Test of Martin Bomber N.B.S.-1 Equipped with Two 400 Hp. Liberty "12" Engines. Air Service Information Circular, vol. 3, no. 290, Oct. 1, 1921, 10 pp., 6 figs. Summary of test results; discussion of flight with one engine; pilot's observations; description of airplane and power plant.

Messenger. Performance Test of Messenger Airplane Equipped with 3-Cylinder 60 Hp. Lawrence Engine. Air Service Information Circular, vol. 3, no. 280, Oct. 15, 1921, 7 pp., 5 figs. Summary of test results; description of airplane and power plant; and pilot's observation.

Multi-Engined. Multi-Engined Commercial Airplanes, Donald W. McIlhiney. Aviation, vol. 11, no. 18, Oct. 31, 1921, pp. 506–507. Gives table of principal data of 44 such airplanes, and discusses main points.

Orenco. The Orenco Type F-4 Five-Place Tourister. Aerial Age Weekly, vol. 14, no. 11, Nov. 21, 1921, pp. 246–248, 4 figs. Built by Ordnance Eng. Corp. Wright E-2 engine; 200 hp. at 1800 r.p.m. Specifications and description

Racing. Airplane Racing and Racing Machines (Flugzeug-Rennen und Rennflugzeuge), Fr Wm Seekatz. Motorwagen, vol 24, no 3, Jan 31, 1921, pp. 48-53, 10 figs Presents table and chart showing results of Gordon Bennett races from 1909 to 1920 Notes on French and American racers, the Verville-Packard biplane the Dayton-Wright monoplane, and the Curtiss-Cox monoplane

Soaring. The Soaring Airplane (Das Segelflugzeug der akademischen Fliegergruppe der technischen Hochschule Hannover), W Blume Zeit fur Flugtechnik u Motorluftschiffahrt, vol 12, no 21, Nov. 15, 1921, pp. 313-316, 9 figs Details of monoplane designed by G. Madelung and constructed under his supervision by student group of Hannover Technical Acad

Speed Meters. N A C A Recording Air Speed Meter, F. H. Norton Aerial Age Weekly, vol. 14, no 7, Oct. 24, 1921, pp 151 and 154, 7 figs Describes new type designed by technical staff of Nat Advisory Committee for Aeronautics, consisting of a tight metal diaphragm of high natural period which is acted upon by the pressure difference of a pilot-static head.

Staggering of Biplane. The Effects of Staggering a Biplane, F H Norton Aerial Age Weekly, vol. 14, no. 5, Oct 10, 1921, pp 103-104, 5 figs. The lift, drag and center of pressure travel are determined for a biplane with a stagger varying from −100 per cent to +100 per cent.

Static Test. Report of Static Test on Engineering Division Messenger Airplane. Air Service Information Circular, vol. 3, no 270, Oct. 1, 1921, 15 pp. 10 figs Particulars of tests carried out at McCook Field, Dayton, Ohio, to determine strength of wings, ailerons, empennage, fuselage, and chassis.

Storage of Parts. Instructions for the Storage of Airplanes, Engines, Their Parts and Accessories. Air Service Information Circular, vol. 3, no. 256, July 15, 1921, 9 pp Deals with storage of wooden airplane parts, airplane materials, engines, armament, equipment and propellers Specifications covering requirements of Air Service for rust-preventing compound for protection against corrosion of aircraft engine

Struts. Tests on Combined Loading of Wooden Struts Air Service Information Circular, vol. 3, no. 276, Oct. 1, 1921, 11 pp., 5 figs. Results of investigation to determine whether test data obtained when a wooden strut is subjected to a column load and also to a side or lateral bending load verify formulas now in use.

Tests. Aerodynamical Report and Tests on the Eggleston Air-Cell Giant Biplane. Aerial Age Weekly, vol. 14, no. 14, Dec. 12, 1921, pp. 323-324 and 326, 4 figs. Report of tests carried out at wind speed of 30 m p h. by Cox-Klemin Aircraft Corp., College Point, L. I.

Truss Ribs. Experimental Reinforced Plywood Truss Ribs, B. C. Boulton. Aerial Age Weekly, vol. 13, no. 25, Aug. 29, 1921, pp. 591-594, 17 figs. Gives tables of data for rib design and direct stresses in rib trusses. Test data on 15 ft. truss ribs. (Concluded.)

Zeppelin. The 1000 Hp. Passenger-Carrying Aeroplane of the Zeppelin works in Staaken, K. Rohrbach. Eng. Progress, vol. 2, no. 11, Nov. 1921, pp. 259-262, 6 figs. Entirely constructed of duralumin. Attained a velocity of 211 km. per hour at trial flights. Equipped with four 260-hp. Maybach engines.

[See also FLYING BOATS; SEAPLANES.]

AIRSHIPS

Commercial Transportation. Commercial Transportation By Dirigibles (Le trafic commercial par ballons dirigeables), L. Hirschauer. La Technique Moderne, vol. 13, no. 6, June 1921, pp. 241-249, 4 figs. Discusses developments, speed and regularity of trips already made, and freight capacity; calculates cost for various lines from Paris.

Mooring. The Mooring of Airships, G. H. Scott. Flight, vol. 13, no. 48, Dec. 1, 1921, pp. 803-804. Discusses mooring on surface of land or water; mooring in the air on one or more wires, and towing; and mooring at a mast. Extract of paper read before Cambridge Univ. Aeronautical Soc.

Non-Rigid, Stresses in. Bending Moments, Envelope, and Cable Stresses in Non-Rigid Airships, C. P. Burgess. Nat. Advisory Committee for Aeronautics, report no. 115, 1921, 14 pp., 4 figs. Describes theory of calculations and methods in use in U. S. Navy Bur. of Aeronautics. Principal stresses are said to be due to gas pressure and unequal distribution of weight and buoyancy, and concentrated loads from car suspension cables. Deals also with variations of tensions in car suspension cables of any type of airship, with special reference to rigid type, due to propeller thrust or inclination of airship longitudinally.

Passenger. Airships for Passenger Transportation, Ralph Upson. Aviation, vol. 11, no. 21, Nov. 21. 1921, pp. 598-600, 5 figs. Discusses advantages of aerial transportation and size and type of ships and terminals. Paper presented to Int. Aero Congress.

The Employment of Airships for the Transport of Passengers, Umberto Nobile. Aerial Age Weekly, vols. 13 and 14, nos. 26, 1 and 2, Sept. 5, 12 and 19, 1921, pp. 618-620, 12-14 and 33-37, 9 figs Indications on the maximum limits of their useful load, distance covered, altitude and speed. From Giornale del Genio Civile, Anno LIX, 1921.

Spain-Argentine Service. Spain to Argentine Airship Service. Aviation, vol. 11, no. 23, Dec. 5, 1921, pp. 656-658, 3 figs. Three Zeppelins are to be used costing about $7,000,000 with terminal facilities costing $8,000,000.

ALCOHOL

Industrial. Manufacture of Industrial Alcohol from the Carob Bean (La fabbricazione industriale dell' alcohol dalle carrube), Giuseppe Mezzadroli Giornale di Chimica Industriale ed Applicata, vol. 3, no 9, Sept. 1921, pp. 399 403 Describes such a plant at Catania, extraction of the sugar, fermentation, distillation and rectification, makes recommendations

ALLOY STEELS

Cracking During Dip Brazing. Report on Cause of Cracking of Alloy Steels During Dip Brazing. Air Service Information Circular, vol. 3, no. 295, Oct 20, 1921, 3 pp., 2 figs. Results of investigation show that two influences contribute to cracking, namely, a sudden rise in temperature after immersion in brass, and sharp changes in cross-sectional area in specimen. Slow preheating to brazing temperature is said to obviate this difficulty.

Impact Tests. Effect of Repeated Impact on Steels (Influence des chocs repétés à la compression sur les aciers), Fernand Éloy. Révue de l'Industrie Minerale, no 19, Oct. 1, 1921, pp. 603 606. Discusses tests with special and carbon steels, showing superiority of former.

Tool Steel. Tool-Steel Specifications—A Hard Nut to Crack, Charles M. Brown. Raw Material, vol. 4, no 10, Oct. 1921, pp. 349-352. Advocates formulation of definite standards as an advantage from user's point of view.

ALLOYS

Carbon-Chromium-Silicon. A New Carbon-Chromium-Silicon Resistance Material. Raw Material, vol. 4, no. 10, Oct. 1921, pp. 359-361, 4 figs. Discusses physical properties of "Silchrome" and gives results of tests made at Columbia University for electric resistance, etc.

Chemical Properties. The Chemical Properties of Alloys (Die chemischen Eigenschaften der Legierungen), G. Tammann. Zeit. fur Metallkunde, vol. 13, no. 12, Sept. 1921, pp. 406-419 and (discussion) pp. 419-424, 27 figs. Deals with limits of influence of chemical media on mixed crystals and the electro-thermal behavior of alloys.

Distribution of Metals in. A Method for Determination of the Percentage Distribution of Metals in Alloys Whose Qualitative Composition is Known (Ueber eine Methode zur Bestimmung der prozentualen Verteilung von Metallen in Legierungen, deren qualitative Zusammensetzung bekannt ist), Karl Schmidt. Chemiker-Zeitung, vol. 45, no. 103, Aug. 27, 1921, pp. 825-826. Method is developed with which it is possible to determine quantitatively the composition of an alloy without destroying it and with the same accuracy as is obtainable by weight analysis.

[See also ALUMINUM ALLOYS; BEARING METALS; MAGNESIUM ALLOYS.]

ALUMINUM

Chill Casting. Chill Casting of Aluminum (Le Moulage en Coquille de l'Aluminium). La Fonderie Moderne, no. 9, Sept. 1921, pp. 254-256, 2 figs. Describes the various operations and alloys to be used.

Industrial Applications. New Industrial Application of Aluminum, Magnesium, Calcium and Sodium (Conférences et exposition publiques des nouvelles applications industrielles de l'aluminium, du magnésium, du calcium et du sodium). Bul. de la Société d'Encouragement pour l'Industrie Nationale, vol. 133, no. 7, July-August-September 1921, pp. 683-956, 186 figs. partly on supp. plates. Papers read at recent Aluminum Exposition, discussing manufacture, properties, alloys, castings, use in electric and food industries, welding, enameling, etc. See also Revue de Métallurgie, vol. 18, no. 9, Sept. 1921, pp. 541-607, 43 figs.

ALUMINUM ALLOYS

Bronzes. On the Heat-Treatment of Aluminum Bronze, A. A. Blue. Chem. & Met. Eng., vol. 25, no. 23, Dec. 7, 1921, pp. 1043-1048, 25 figs. Concludes from experiments that heat treatment produces marked and consistent changes in Brinell and scleroscope hardness and has little or no effect on tensile strength and yield point.

Heat Treatment. Heat Treatment of Certain Complex Aluminum Alloys (Sur le traitement thermique de certains alliages complexes d'aluminium), Léon Guillet. Comptes Rendus des Séances de l'Académie des Sciences, vol. 173, no. 21, Nov. 21, 1921, pp. 979-982. Examines part taken by constituents of duralumin (Cu, Mg, Mn, Si, Fe) in the high resistance of the alloy; describes experiments with Al-Cu, Al-Si, Al-Si-Mg, Al-Cu-Si-Mg alloys.

Researches. Researches on Aluminium Alloys, Walter Rosenhain, Sydney L. Archbutt and D. Hanson. Engineering, vol. 112, nos. 2913 and 2914, Oct. 28 and Nov. 4, 1921, pp. 613-615 and 644-645, also Engineer, vol. 132, nos. 3435 and 3436, Oct. 28 and Nov. 4, 1921, pp. 461-463 and 489-490. Brief account of principal contents of report to Alloys Research Committee. Deals with cast and wrought alloys; permanence and constitution of alloys.

APPRENTICES, TRAINING OF

Shipyards. American Shipyard Apprenticeships, Evening Schools and Scholarships, Charles F. Bailey. Advance Copy, Soc. of Naval Architects & Mar. Engrs., meeting Nov. 17-18, 1921, no. 8, 10 pp., 1 fig. Reviews present situation, including requirements for apprenticeship, pay, bonus, evening schools, scholarships, etc., and makes suggestions for improvement.

AUTOMOBILE ENGINES

Anti-Freezing Solutions. Anti-Freezing Solutions, O. B. Zimmerman. Jl. Soc. Automotive Engrs., vol. 9, no. 5, Nov. 1921, pp 307-310 and (discussion) 310-312 Progress report of Committee of S.A.E., discussing cooling media and their ideal requirements.

Camshafts. Manufacture of Accurate Camshafts. Machinery (Lond.), vol. 19, no 477, Nov. 17, 1921, pp. 189-191, 9 figs. Description of important operations, and complete tabulated data on manufacturing procedure in making camshafts for a high-grade motor-car.

Carburetors. See CARBURETORS.

Cylinders. Machining the "Bean" Motor Cylinder I. William Chubb. Am. Mach., vol. 55, no. 21 Nov. 24, 1921, pp. 827-830, 10 figs. Methods used in well-equipped English motor plant. Cylinders produced on American machine tools. Power-washing machine

The Molding of Automobile Cylinder Blocks (Formerei von Auto-Zylinderblocken), Carl Irresberger. Stahl u. Eisen, vol. 41, nos. 35, and 43, Sept. 1 and Oct. 27, 1921, pp. 1217-1222 and 1529-1533, 48 figs. Notes on upright molding of a one-piece six-cylinder block.

Peugeot Co., France. Internal Combustion Engines of the Peugot Automobile Company (Le moteur à injection de la Société des Automobiles Peugeot) Henri Petit. La Technique Automobile et Aerienne vol. 12, no. 113, 1921, pp. 42-49, 4 figs. Discusses construction and operation of the various parts including combustible mixture, atomizer, injector pumps, regulators, etc.

The Heavy Oil Engine of the Peugeot Automobile Co. (Le Moteur a huile lourde de la Société des Automobiles Peugeot), Henri Petit. La Vie Automobile, vol. 17, no. 741, Nov. 10, 1921, pp. 415-421 7 figs. Describes the Peugeot motor (Tartrais patent) principles of which are (1) combustion in a hot chamber, (2) high compression, (3) constant volume combustion, (4) fuel injection in cylinder head. Atomizer, feed pump, efficiency, etc.

AUTOMOBILE FUELS

Air-Fuel Mixtures. Condensation Temperatures of Gasoline and Kerosene-Air Mixtures, Robert E. Wilson and Daniel P. Barnard. Jl. Soc. Automotive Engrs., vol. 9, no. 5, Nov. 1921, pp. 313-319, 11 figs. Describes simple and reliable method for determining temperatures of initial condensation of fuels from air-fuel mixtures, and an approximate method of determining temperatures of partial condensation in such mixtures. From paper read before Am. Chem. Soc.

Benzol. See BENZOL.

Mixed. Diagram for Mixed Automobile Fuels (Rechentafel fur Mischkraftstoffe), Wa. Ostwald. Chemiker-Zeitung, vol. 45, no. 112, Sept. 17, 1921, p. 897, 1 fig. Presents triangle chart for determination of specific weight and heating value for mixtures of benzol, tetraline and alcohol when percentage weight of composition is known.

Oil-Shale. Motor Car Fuel Prospects in the Oil Shales. Automotive Manufacturer, vol. 63, no. 7, Oct. 1921, pp. 7-10. Discusses quality and composition, distillation analysis, and production with steam.

Standard German. Germany's New Standardized Motor Fuel, Benno R. Dierfeld. Automotive Industries, vol. 45, no. 20, Nov. 17, 1921, pp. 974-975, 2 figs. Mixture of benzol and alcohol with tetralene has produced excellent results in road tests and races.

AUTOMOBILES

Beardmore 11-Hp. The 11 hp. Beardmore. Autocar, vol. 47, no. 1357, Oct. 22, 1921, pp. 717-718, 3 figs. Describes 1922 model embodying minor modifications.

Belsize-Bradshaw 9-Hp. The 9 hp. Belsize-Bradshaw. Autocar, vol. 47, no. 1358, Oct. 29, 1921, pp. 803-804, 4 figs. Specifications and description, including oil cooling for engine, automatic oil lubrication, etc.

Brakes, Four-Wheel. The History of Four-Wheel Brakes. Autocar, vol. 47, no. 1361, Nov. 19, 1921, pp. 1057-1064, 21 figs. A series of articles on brakes, including, operating front wheel brakes, Servo brakes, and four-wheel brake tests.

Design. Car Design and Production. Autocar, vol. 47, no. 1362, Nov. 26, 1921, pp. 1123-1126, 7 figs. Shows how design, workshop processes and material costs influence selling price of a motor vehicle.

Frame Stresses. Automobile Frame Stresses, Ethelbert Favary. Jl. Soc. Automotive Engrs., vol. 9, no. 5, Nov. 1921, pp. 301-303 and (discussion) 303-306, 3 figs. Gives frame-stress calculations intended to enable the designer to proportion frames and parts with the view of eliminating some of the factors that are productive of excessive weight which causes fuel wastage. Laboratory tests of tensile strength, elastic limit, yield point, etc., of materials.

Francon Light. The Françon Light Car (La Voiturette Francon), A. Contet. La Vie Automobile, vol. 17, no. 739, Oct. 10, 1921, pp. 369-372, 7 figs. 10 hp ; two separate cylinders; consumes 296 gr. gasoline per hp.-hr. Detailed description of construction and equipment.

German 1921 Show. The German Automobile Exhibition 1921, A. Heller. Eng. Progress, vol. 2, no. 11, Nov. 1921, pp. 241-246, 9 figs. Discusses motors, carburetors, radiators, electric equipment, head lights, speed change gear, back-axle drive, road wheels and springs.

The German 1921 Automobile Show (Die Deutsche Automobil-Ausstellung 1921), A. Heller. Zeit. des Vereines deutscher Ingenieure, vol. 65, no. 45, Nov. 5, 1921, pp. 1155-1159, 7 figs. Most important

innovations are said to be use of suspended inlet valves and steel cylinders for engines; the dimensioning of cylinders in excess of requirement of their driving gear, which makes it possible to construct car without the usual control-gear mechanism; progress in field of electric starting and lighting installations new Rumpler rear-axle drive; and new aluminum-silicium alloy known as silumin, from which complete rear-axle housings are cast.

Italian S.P.A. The 30–40 hp. Six-Cylinder S.P.A. Autocar, vol. 47, no. 1358, Oct. 29, 1921, p. 794, 2 figs. Specifications and description, including anti-rolling device.

Machining Differential Gear Case. Methods and Tools Used in Machining the Peerless Differential Carrier and Gear Case, Fred H. Colvin. Am. Mach., vol. 55, no. 23, Dec. 8, 1921, pp. 912–914, 11 figs. Turret lathe tooling for special jobs; drilling fixture for rapid handling of work; gages for surfaces which are not easy of access.

Mechanical Features. Progress in Design. Autocar, vol. 47, no. 1360, Nov. 12, 1921, pp. 945–953, 21 figs. Notes on engine design, gas passages, valves, lubrication, carburation, transmission, brakes, steering, suspension, and wheels.

Repair Service. Automotive Service Methods and Equipment, Howard Campbell. Am. Mach., vol. 55, no. 22, Dec. 1, 1921, pp. 870–873, 7 figs. Details of service plant of Hellman Motor Corp., Long Island City, N. Y.

Rumpler Streamline. The New Rumpler Streamline Automobile ("Tropfenwagen"), Curt Eppinger. Zeit. für Flugtechnik u. Motorluftschiffahrt, vol. 12, no. 19, Oct. 15, 1921, pp. 287–289, 11 figs. Based on experiences in airplane construction. Entire drive is located in rear and the streamline form is adopted for body. Advantages and possibilities of new type are set forth.

Standard Motor Co. An 8 hp. Four-Cylinder Standard. Autocar, vol. 47, no. 1358, Oct. 29, 1921, pp. 791–793, 8 figs. Specifications and description of Standard Motor Co.'s 8-hp. and 11-hp. cars.

AVIATION

Commercial. Commercial Aviation in France (L' Aviation Commerciale Française), L. Hirschauer. La Technique Moderne, vol. 13, no. 4, April 1921, pp. 145–153, 12 figs. Gives tabulation of lines in existence; shows development of aerial transport companies, their flying machines and government action; reviews activity in other countries.

Technique and Economics in Commercial Aviation (Technik und Oekonomik im Luftverkehr mit Flugzeugen), E. Offermann. Zeit. für Flugtechnik u. Motorluftschiffahrt, vol. 12, nos. 19 and 20, Oct. 15 and 31, 1921, pp. 289–298 and 301–302. Oct. 15. Technical requirements of traffic airplanes with special regard to the Junkers airplanes. Oct. 31: Organization problems of air traffic. Prospects of air traffic in Argentine.

Developments and Progress. Aviation, Present and Future (L'Aviation d'hier and de demain), Louis Breguet. L'Aerophile, vol. 29, no. 17–18, Sept. 1–15, 1921, pp. 265–272, 1 fig. Discusses from a technical standpoint what has been accomplished so far and what the possibilities are for aerial transportation.

B

BALANCING

Reciprocating Masses. The Exponential Method in the Analysis of the Balance of Reciprocating Masses, P. Cormack. Engineering, vol. 112, no. 2919, Dec. 9, 1921, pp. 778–780, 1 fig. Calculation of inertia forces for radial and rotating cylinder engines.

Rotating Parts. Balancing Rotating Parts (Sur l'equilibrage des pieces en rotation), P. Lemaire. Le Technique Moderne, vol. 13, no. 6, June 1921, pp. 249–257, 27 figs. Discusses static and dynamic balancing of machinery.

BALLOONS

Pilot. Resistance of Air to Spheres and the Rising Speed of Pilot Balloons (La résistance de l'air au mouvement des sphères et la vitesse ascensionnelle des ballons pilotes), C.-E. Brazier. Compt. Rendus des Séances de l'Académie des Sciences, vol. 173, no. 16, Oct. 17, 1921, pp. 644–646. Discusses determination of K, the coefficient of resistance, and gives table of calculated and experimental values for it.

BEAMS

Irregularly Distributed Loads. Beams with Loads Irregularly Distributed, T. Thompson. Engineering, vol. 112, nos. 2915 and 2916, Nov. 11 and 18, 1921, pp. 656–658 and 686–689, 7 figs. Describes method for speedy and accurate calculation of bending moments and deflections of beam with irregularly distributed loading.

BEARING METALS

Babbitt. Characteristics of Bearing Metals, Edward T. Keenan. Power, vol. 54, no. 25, Dec. 20, 1921, pp. 977–978. Composition of various babbitt metals for various kinds of bearings. List of babbitts and their compounds.

Industrial Value. Bearing Metals and Their Industrial Value, J. Czochralski. Brass World, vol. 17, nos. 9 and 10, Sept. and Oct. 1921, pp. 245–248 and 281–286, 33 figs. Sept.: Discusses alloys in which tin is replaced by lead, and experiments carried out for the purpose. Oct.: Methods of testing and comparative efficiency of bearing metals. (Abstract.) Zeit. f. Metallkunde.

BEARINGS

Hand vs. Machine-Finished. Hand Versus Machine Finished Bearings, E. A. Dixie. Am. Mach., vol. 55, no. 22, Dec. 1, 1921, pp. 888–890. Comparison of machine and hand-finished surfaces. Some examples of better and quicker work.

BEARINGS, BALL

Friction and Safe Load. Friction and Carrying Capacity of Ball and Roller Bearings, H. L. Whittemore and S. N. Petrenko. U. S. Bur. Standards Technologic Papers, no. 201, Oct. 6, 1921, 34 pp 30 figs. Account of experiments undertaken to determine maximum safe load and static friction under load of ball and flexible roller bearings. Results agree roughly with Hertz's theory, differences being ascribable to inhomogeneity of material.

Grinders. Use of Ball Bearings as Adapted to Grinders, Donald A. Hampson. Can. Machy., vol. 26, no. 17, Oct. 27, 1921, pp. 30–32 and 36, 9 figs. Discusses advantages as to lower cost of production, increased output, higher efficiency, saving of power, etc.

BEARINGS, ROLLER

Calculation. Practical Calculations of Roller Bearings (Calcul pratique des roulements a rouleaux), P. Massot. La Technique Moderne, vol. 13, no. 5, May 1921, pp. 193–197, 3 figs. Discusses cylindrical and conical roller bearings and works out formulas. Comparison with ball bearings.

Types. Usual Forms of Roller Bearings (Les formes usuelles de roulements a rouleaux), La Technique Moderne, vol. 13, no. 6, June 1921, pp. 258–263, 22 figs. Describes products of various American, British, French and Swedish firms.

BENZOL

Production in Gas Works. The Production of Benzol in Medium-Size and Small Gas Works (Die Benzolgewinnung in mittleren und kleinen Gaswerken), H. Menzel. Gas- u. Wasserfach, vol. 64, no. 19, May 7, 1921, pp. 294–296, 2 figs. Describes improved type of benzol plant constructed by Berlin-Anhalt Machine Constr. Corp. by means of which, it is claimed, a quality of benzol well adapted for engine drive can be recovered from gas produced in gas works.

BLAST-FURNACE GAS

Burning under Boilers. Burning Blast-Furnace Gas Under Boilers, Gordon Fox and F. H. Willcox. Power, vol. 54, no. 24, Dec. 13, 1921, pp. 930–931. Discusses gas burner, ignition, combustion chamber, baffling, and draft losses through boiler passes.

BLIND

Employment of. The Employment of the Blind in Workshops. Engineering, vol. 112, no. 2917, Nov. 25, 1921, pp. 715–717, 7 figs. Deals with experience gained in Germany in employment of blind on machine work, and machining operations performed by blind at the Siemens-Schuckert Works.

BLUEPRINTING

High-Speed Machine. A High-Speed Blue Printing Machine. Engineer, vol. 132, no. 3438, Nov. 18, 1921, p. 345, 5 figs. Describes new photo-printing machine brought out by B. J. Hall & Co., Ltd., London.

BOAT LIFTS

120-ft. Lift. Elevators for Raising Boats to Considerable Heights (Elevators di navi per grandi altezze de sollevamento). L'Industria, vol. 35, no. 17, Sept. 15, 1921, pp. 391–394, 5 figs. Describes installation designed by four German companies for raising boats 36 meters, which works successfully.

BOILER FEEDWATER

Treatment. Boiler Feed Water Treatment and Treatment Control, E. C. Bashore. Powec Plant Eng., vol. 25, no. 21, Nov. 1, 1921, pp. 1050–1052. Causes of scale, corrosion, foaming, embrittlement, and methods of treatment. (Abstract). Paper read at Nat. Exposition of Chem. Industries.

The Interior Treatment of Boiler Waters, C. R. Knowles. Ry. Age, vol. 71, no. 20, Nov. 12, 1921, pp. 935–936. Discusses introduction of substances into boiler to prevent scale, corrosion, foaming or other ill effects of bad water.

The Treatment of Boiler Feed Water, Robert June. Power House, vol. 14, no. 21, Nov. 5, 1921, pp. 21–23, 3 figs. Discusses artificial zeolite systems and evaporating methods.

BOILER OPERATION

Coal Consumption, Control of. The Influence of Weather on Coal Consumption, Malcolm C. W. Tomlinson. Management Eng., vol. 1, no. 6, Dec. 1921, pp. 321–326, 13 figs. Describes method of using outside temperatures to check boiler operation.

BOILER PLANTS

Economical Design. Boiler and Furnace Economy, D. S. Jacobus. Mech. Eng., vol. 43, no. 12, Dec. 1921, pp. 779–782. Deals with such questions as when it will pay to use economizers in a new plant; most economical rating at which to operate a boiler; limitations imposed on efficiency by inability of furnace brickwork to withstand temperatures available with many classes of fuel; furnace volume and length of flame travel; use of air heaters, etc.

Boiler-House Management, David Brownlie. Iron & Coal Trades Rev., vol. 103, nos. 2803 and 2804, Nov. 18 and 25, 1921, pp. 721–722 and 700–702. Nov. 18: Discusses efficient design and equipment of boiler plant and scientific control of the working of the plant. Types of boilers and relative advantages and disadvantages. Nov. 25: Discusses mechanical stoking, economizers and feedwater heaters, superheaters, forced or induced draft, and auxiliary machinery. (Abstract). Paper read before South Wales Inst. Engrs.

Steam Accumulators. Steam Accumulators, System Ruths (L'Accumulateur de vapeur Ruths), E.-G. Constam-Gull. Le Génie Civil, vol. 79, no. 22, Nov. 26, 1921, pp. 453–457, 13 figs. A Swedish patent apparatus designed to equalize boiler pressure. Describes a number of installations in metallurgical and electric power plants.

BOILERS

Corrosion. Corrosion Caused by Carbonic Acid (Rostbildung durch Kohlensäure), G. Bruhns. Chemiker-Zeitung, vol. 45, no. 111, Sept. 15, 1921, pp. 885–887. Gives results of investigation of corrosive effect of free carbonic acid in steam and condensation water, and means for its prevention.

Preheating with Flue Gas. Utilizing Flue Gases to Preheat Air to Furnace—Consideration o Some of the Problems Involved, E R. Welles and C. T. Mitchell. Power, vol. 54, no. 22, Nov. 29, 1921, pp. 844–846, 1 fig. Points out that rough calculations (the best that can be made with available data indicate reasonable possibility of economic application of preheating.

Water Works. Selecting Steam Boilers for Water Works, F. W. Dean. Fire & Water Eng., vol. 70, nos. 22 and 23, Nov. 30 and Dec. 7, 1921, pp. 1007–1008, 1014 and 1027–1029 and 1053–1054 and 1058. Importance of choosing most economical type. Various kinds of boilers with their characteristics considered. Proper setting and fuel to be used. Boiler safety. (Abstract). Paper read before N. E. Water Works Assn.

BOILERS, WATER-TUBE

Vertical. Feedwater-Heater Vertical Water-Tube Boilers with Combined Trough-Grate and Step-Grate Furnace for Burning Low-Grade Lignite (Vorwärmer-Steilrohrkessel mit kombinierter Muldenrost-Treppenrostfeuerung zur Verbrennung minderwertiger Braunkohle). Wärme- u Kälte-Technik, vol. 23, no. 14, July 15, 1921, pp. 159–160, 1 fig. Points out advantages of new boiler system which consists of three upper drums connected with the two bottom drums through tubes. Built by Karlsruhe Machine Constr. Corp.

BRAKES

Combination Air and Vacuum. Brakes on the Paulista Railroad (Frenos para el Ferrocarril Paulista), F. H. Parke. Ingenieria Internacional, vol. 6, no. 6, Dec. 1921, pp. 348–351, 3 figs. A combination of air and vacuum brake for electric locomotives drawing trains provided with air brakes, constructed by Westinghouse Air Brake Co.

Pneumatic. Continuous Brake for Freight Trains (Le freinage continu des trains de marchandises), G. Tongas. La Technique Moderne, vol. 13, no. 10, Oct. 1921, pp. 417–425, 6 figs. Describes the Lipkowski brake, a single chamber pneumatic brake, used on some French locomotives for seven years with success.

Westinghouse Double-Capacity. Exceptional Train Loading in the United States and the Westinghouse Double Capacity Brake. Ry. Gaz., vol. 35, no. 21, Nov. 18, 1921, pp. 769–771, 5 figs. Tests with 75,100 and 110-car coal trains, respectively 12,000, 16,000 and 17,250 American tons, on Virginian railway, fitted with Westinghouse empty and load brake.

BRASS

Compressibility. Compressibility of Brasses at Temperatures up to 800 Deg. C. Engineering, vol. 112, no 2918, Dec. 2, 1921, p. 770, 3 figs. Results of series of experiments on compressibility of copper and various brasses at temperatures ranging from 20 to 800 deg. cent. carried out at Hirsch Brass Works, Inc., Eberwalde, Germany. Translated from Zeit. für Metallkunde, vol. 12, pp. 340–358 and vol. 13, pp. 305–315.

Heat Treatment. Heat-Treatment of Brass and Brasses Containing Tin, Léon Guillet. Chem. & Met. Eng., vol. 25, no. 22, Nov. 30, 1921, pp. 1009–1014, 16 figs. Brasses containing a little beta respond to heat treatment; tin-brasses, developing special constituent analogous to delta in bronzes, may have their physical properties changed very notably by proper annealing and quenching. From Revue de Métallurgie, July 1921.

Hot-Working. Hot Working of Brass (Le travail du laiton a chaud), A. Devilliers. La Technique Moderne, vol. 13, no. 5, May 1921, pp. 206–209, 8 figs. Discusses hot rolling, critical content of lead, effect of aluminum and pros and cons of hot and cold working.

BRASS FOUNDING

Electric-Furnace Melting. Brass Melting in Electric Furnaces (Messingschmelzen im elektrischen Ofen), Herbert Hein. Siemens-Zeit., vol. 1, no. 10, Oct. 1921, pp. 380–385, 5 figs. Describes induction furnace developed during war. Furnaces of this type for three-phase and two-phase current and charges of 500 to 1000 kg. have been in operation for several years, consuming 100 and 150 kw. at power factor of 0.4 to 0.6 at 50 cycles. Higher hygienic qualities are claimed for induction furnace than for one of arc type due to smaller amount of injurious zinc fumes.

BUSHINGS

Drill. Drill Bushings (Bohrbuchsen), Fritz Herkner. Betrieb, vol. 4, no. 1, Oct. 8, 1921, pp. 8–12, 32 figs.

For giving to drills, reamers, countersinks, etc. the necessary accuracy in guidance, direction and position. Notes on their manufacture, dimensions, adjustment, and security against being pulled out.

C

CALORIMETERS

Gas. A New Gas Calorimeter (Ein neues Gaskalorimeter), E. Langthaler. Gas- u. Wasserfach, vol 64, no. 6, Feb. 5, 1921, pp. 83-86, 2 figs. Describes Union calorimeter designed by O. Dommer, which, as shown by test results, has a high degree of accuracy. It is easily transportable and adaptable for many uses.

Recording. Report on Recording Calorimeters. Gas World, vol 75, no. 1943, Oct. 15, 1921, pp. 314-319 and (discussion) 319-321, 5 figs. Fifth report of Research Sub-Committee of Gas Investigation Committee giving results of tests made.

CAR LIGHTING

Generators. The Economy of Electric Car Lighting (Die Wirtschaftlichkeit elektrischer Zugbeleuchtung), H. Hoepner. Verkehrstechnik, vol. 38, no. 25, Sept. 5, 1921, pp. 383-395. Demonstrates advantages of generator lighting with auxiliary batteries over pure storage-battery lighting.

CARBURETORS

Aircraft. Instructions to Designers of Aircraft Carburetors. Air Service Information Circular, vol. 3, no. 291, Oct. 20, 1921, 4 pp., 2 figs. Deals with general requirements of carburetor design, gasoline inlet connection, gasoline strainer, float chamber, metering jets, air intake pipe, venturis, throttles, mixture control, performance, tests inspection, etc.

Griffon. The Griffon Carburetor (La carburateur Griffon), Henri Petit. La Vie Automobile, vol. 17, no. 739, Oct. 10, 1921, pp. 378-381, 4 figs. Discusses the various parts and their operation.

Kerosene Carburetion. Actual State of Kerosene Carburetion (Etat actuel de la carburation au petrole lampant), Sigma. La Métallurgie, vol. 53, no. 45, Nov. 10, 1921, pp. 2101-2102. Discusses mixing, ignition, combustion, flame control, etc. (Concluded)

Metering Characteristics. Report on the Control of Carburetor Metering Characteristics by the Supplementary Admission of Air. Air Service Information Circular, vol. 3, no. 292, Oct. 20, 1921 14 pp., 9 figs. Results of test to determine characteristics of mixture-control device operating on principle of supplementary admission of air, particularly as applied to high-compression, over-dimensioned aviation engine, under laboratory and flight conditions.

Testing Zenith. Testing a Zenith Carburetor (Essai d'un carburateur Zénith a triple diffuseur sur voiture 16 hp. Panhard S.S.), Henri Petit. La Vie Automobile, vol. 17, no. 739, Oct. 10, 1921, pp. 374-375, 2 figs. Details of three tests on a 16-hp. Panhard.

CARS

Electric. Illinois Central Steel Suburban Coaches. Ry. Mech. Engr., vol. 95, no. 12, Dec. 1921 pp. 755-759, 11 figs. Designed for future electrification; doors electrically controlled; total weight 92,100 lb.

CARS, COAL

Steel Hopper. All-Steel Coal Hopper Wagons for Bengal-Nagpur Railway. Ry. Engr., vol. 42, no. 502, Nov. 1921, pp. 405-409, 5 figs. High-capacity hopper wagons constructed by Midland Railway Carriage & Wagon Co., Ltd., Birmingham, for Bengal-Nagpur Railway, to the design of J. W. Barry.

CARS, FREIGHT

Box. The Use of Ordinary Box Cars for Shipping Fruit, Vane G. Gibson and Herbert Graff. Ry. Rev., vol. 69, no. 20, Nov. 12, 1921, pp. 643-646, 7 figs. Tests undertaken by Department of Agriculture show most practical means for ventilating box cars. (Abstract).

Container. Avoidable Waste in Car Operation—The Container Car, Walter C. Sanders. Mech. Eng., vol. 43, no. 12, Dec. 1921, pp. 799-802, 9 figs. Describes "container" cars recently placed in service on N. Y. Central lines and others having improvements on original type which are now under construction. Advantages of described car are enumerated.

Wood in Construction of. The Use of Wood in Freight Car Construction, H. S. Sackett. Ry. Age, vol. 71, no. 22, Nov. 26, 1921, pp. 1037-1042, 6 figs. Relative advantages of double- and single-sheathed box car; composite gondola car, advantages of composite design; etc. Gives table of lumber grades and dimensions.

CARS, PASSENGER

All-Steel. Illinois Central Suburban Operation and Equipment. Ry. Rev., vol. 69, no. 21, Nov. 19, 1921, pp. 669-677, 14 figs. Describes new all-steel cars just put in service as first step toward electrification.

New All-Steel Suburban Coaches for the South African Railways. Ry. Gaz., vol. 35, no. 20, Nov. 11, 1921, pp. 722-725, 6 figs. Describes all-steel composite bogie coaches built by Leeds Forge Co., Ltd., constructed on central gangway principle.

Design. On the Question of Passenger Carriages, W. J. Tollerton. Bul. Int. Ry. Assn., vol. 3, no. 10, Oct. 1921, pp. 1399-1440, 52 figs. Gives list of questions and answers regarding general types and arrangements of passenger carriages used in U. S., Canada and Mexico, details of construction of principal parts of carriages, lighting, heating, ventilating, etc.

CARS, TANK

Milk. Handling Milk in Specially Constructed Tank Cars. Ry. Mech. Engr., vol. 95, no. 12, Dec. 1921, pp. 763-764, 3 figs. Large glass-lined steel tanks save expense in handling and haulage, refrigeration in transit eliminated.

CAST IRON

Self-Corrosion. Self-Corrosion of Cast Iron and Other Metals in Alkaline Soils, W. Nelson Smith and J. W. Shipley. Elec. Ry. Jl., vol 58, no 21, Nov. 19, 1921, pp. 911-912. Results of investigation to show that city water main external corrosion could not be due to electrolysis from stray currents. (Abstract.) Paper read before Eng. Inst. of Can.

CENTRAL STATIONS

Auxiliary Drives. Relation of Auxiliary Drives to Heat Balance, J. R. McDermet. Power, vol. 54, no. 23, Dec. 6, 1921, pp. 888-890, 1 fig. Deals with direct steam drive, motor drive, house turbines, combination drives, and feedwater heating by bleeder condensers.

Hartford, Conn. South Meadow Station. Power Plant Eng., vol. 25, no. 24, Dec. 15, 1921, pp. 1177-1184 and 1210-1217, 23 figs. Describes new plant of Hartford Elec. Light Co. with ultimate capacity of 130,000 kw. at 11,000 volts. Centrifugal auxiliary pumps, inbuilt economizers, washed air for cooling generators, centralized station control. See also Elec. World, vol. 78, no. 24, Dec. 10, 1921, pp. 1163-1166, 6 figs.

Manchester, N. H. Central Station Service for Manchester, N. H. Power Plant Eng., vol. 25, no. 22, Nov. 15, 1921, pp. 1079-1087, 13 figs. Hydro-electric and steam standby stations of Manchester Traction, Light & Power Co.

Oakland, Cal. Oakland Station of the Pacific Gas & Electric Co., Charles W. Geiger. Power Plant Eng., vol. 25, no. 21, Nov. 1, 1921, pp. 1033-1039, 10 figs. Describes 12,500-kw. addition to Station C, turbo-generator, circulating pump, fuel oil, water supply, etc.

Superpower. A Superpower System for the Region Between Boston and Washington, W. S. Murray. U. S. Geol. Surv. professional paper 123, 1921, 261 pp., 61 figs. and 11 supp. plates. Market for superpower energy will be furnished by electric utilities, industries, and railroads. Estimated requirement for energy supplied through electric utilities for municipal, private, industrial, and railroad purposes in 1930 is 31,000,000,000 kw-hr., which could be supplied by coördinated power system such as is described. Study of 96,000 manufacturing establishments operating within superpower zone shows that by 1930, they can save $190,000,000 annually above fixed annual charges against capital investment of $185,000,000. See also Power Plant Eng., vol. 25, no. 24, Dec. 15, 1921, pp. 1185-1187, 1 fig.

CHARTS

Nomograms. Graphic Charts (Graphische Tafeln), Wilhelm Vieser. Bauingenieur, vol. 2, no. 21, Nov. 15, 1921, pp. 569-575, 6 figs. Review of nomographic methods, and construction of charts. Bibliography.

Scale Selection. Scale Selection for Z Charts, Arthur R. Burnet. Management Eng., vol. 1, no. 6, Dec. 1921, pp. 365-370, 4 figs. Describes new method of chart making and curve plotting and compares it with older method.

CHIMNEYS

Tall, Design of. Notes on the Design of Tall Chimneys and Their Foundations, J. M. Wade. Roy. Engrs. Jl., vol. 34, no. 5, Nov. 1921, pp. 209-219, 6 figs. Discusses design, height, draft, and calculations, including calculations of gases formed by combustion of one ton of coal, and for height and outlet of a chimney for furnaces consuming two tons of fuel per hour.

CHROME STEEL

Automobile Industry. Chromium Steels and Irons, Leslie Aitchison. Iron & Coal Trades Rev., vol. 103, no. 2802, Nov. 11, 1921, pp. 686-687. Discusses alloy and carbon steels, effect of alloying on critical temperature, mechanical properties, stainless steels, and vanadium additions, especially in connection with the automobile industry.

Mechanical Properties. Chromium Steels and Iron, Leslie Aitchison. Engineering, vol. 112, nos. 2918 and 2919, Dec. 2 and 9, 1921, pp. 771-772 and 805-807, 5 figs. Brief account of general effect which chromium exerts upon steels, followed by description of mechanical properties of chrome steels. Paper read before Instn. Automobile Engrs.

CHROMIUM

Alloys of. Chromium Alloys (Les alliages industriels de chrome), J. Herbert. La Technique Moderne, vol. 13, no. 5, May 1921, pp. 197-205. Discusses metallic chrome, ferro-chrome, silico-chrome, chrome and chrome-nickel steels, chrome salts, etc.

COAL HANDLING

Plants. Coal and Ash-Handling Plant of the Royal Naval Cordite Factory, Near Poole, George F. Zimmer. Engineering, vol. 112, no. 2916, Nov. 18, 1921, pp. 706-707, 7 figs. Railway sidings on which coal arrives and from which ashes leave, run alongside and parallel with boiler-house; full trucks arrive on inner track and pass over a large track hopper into which coal is dumped by truck tippler, by completely overturning trucks.

Reinforced-Concrete Coal-Handling Plant with Storage Bunker (Kohlenförderanlage in Eisenbeton fur den Betrieb der Firma F. A. Schmidt in Guben), A. Burghardt. Beton u. Eisen, vol 20, no. 16, Oct. 5, 1921, pp. 177-178, 7 figs. Installation built in 1919 consists of a 7.2-m. long, 3.6-m.-wide bunker for storage of 80 cu. m. of lignite; and a smaller bunker, 2.64 m. long and 2.5 m. wide for 20 cu. m.

COLUMNS

Buckling under Axial Load. Buckling of Elastic Structures, H. M. Westergaard. Proc. Am. Soc. Civ. Engrs., vol. 47, no. 9, Nov. 1921, pp. 455-533, 14 figs. Investigation deals with structural actions in which stresses are not proportional to loads, although proportional limit of material has not been exceeded and deflections remain small. Describes astatic and in particular, heterostatic action. Deals also with columns carrying axial and transverse loads at same time. Formulas are given for buckling of slabs and systems of crossing-beams. Classified bibliography.

COMBUSTION

Controlling Rate. Controlling the Rate of Combustion. Sanitary and Heating Eng., vol. 96, no. 11, Nov. 18, 1921, pp. 313-314, 2 figs. Discusses hydraulically operated damper regulators in low pressure heating plants.

COMPRESSED AIR

Intercooling. Value of Intercooling Compressed Air, C. K. Bennett. Power Plant Eng., vol. 25, no. 23, Dec. 1, 1921, pp. 1142-1144, 5 figs. Methods and means of cooling air during and after compression.

Pneumatic Mail Tubes. Pneumatic Street Tubes in London, A. B. Eason. Compressed Air Mag., vol. 26, no. 11, Nov. 1921, pp. 10279-10282, 8 figs. Used for conveying parcels, letters, newspapers and other matter which must be delivered expeditiously. Describes machinery for supplying compressed air, and terminal apparatus.

CONDENSERS, STEAM

Cooling-Water Treatment. Chemical Treatment of Water for Cooling Condensers (Du traitement chimique des eaux servant à la réfrigération des condenseurs), G. Paris. Chaleur et Industrie, vol. 2, no. 18, Oct. 1921, pp. 634-642, 12 figs. Describes Balke process which changes bicarbonate of lime and magnesium into chlorides by addition of hydrochloric acid, and the Hulsmeyer process depending on thermic action and addition of sodium carbonate.

CONVEYORS

Mold. Conveyor System Cuts Moulding Costs, Herbert H. Leonard. Can. Manufacturer, vol. 41, no. 11, Nov. 1921, pp. 31-35, 11 figs. Molding car wheels on jolt machines is made possible by adoption of conveyor systems for transferring molds, flasks and sand, supplemented by I-beam trolleys and gravity conveyors.

New System. Tramrail Reduces Labor Force to Half. Iron Age, vol. 108, no. 24, Dec. 15, 1921, pp. 1523-1525, 3 figs. States that marked reduction in production costs has been effected by Globe Machine & Stamping Co., Cleveland, by installation of new conveying system and japanning equipment.

COST ACCOUNTING

Job Cards. Job Cards, Hubert Bentley. Eng. & Indus. Management, vol. 6, no. 19, Nov. 10, 1921, pp. 533-534, 2 figs. Outlines useful method of keeping distinct record of time taken on jobs for costing purposes. Describes specimen job cards.

COST SYSTEMS

Foundry. Advantages of a Foundry Cost System, Robert E. Belt. Iron Age, vol. 108, no. 21, Nov. 24, 1921, pp. 1351-1353. Points out that it forms basis for establishing selling price and indicates degree of efficiency of various departments. Paper read before Nat. Founders' Assn.

CRANES

Dock. New Special Types of Mammoth Dock Cranes (Neue Sonderbauarten von Riesenwerftkranen im Ausland), H. Wintermeyer. Fördertechnik u. Frachtverkehr, vol. 14, no. 23, Nov. 11, 1921, pp. 289-291, 6 figs. Describes examples of English and American stationary and floating-dock mammoth cranes.

Floating. Floating Crane for Coaling Vessels. Engineering, vol. 112, no. 2919, Dec. 9, 1921, p. 784, 5 figs. partly on p. 592. New crane recently installed in Montreal Harbor by George Hall Coal Co. of Can., Ltd. Its features include a gooseneck boom which enables it to deliver coal into deck shoots on either side of steamer without moving its station. Slewing angle of boom is 180 deg., enabling it to coal not only from its own stock, but from coal barges alongside.

Metallurgical Industry. Modern Cranes and Conveyors in the Metallurgical Industry (Les appareils modernes de levage et de manutention dans l'industrie métallurgique), Lucien Dujardin. L'Outillage, vol. 230, no. 42 Oct. 20, 1921, pp. 1087-1103, 50 figs. A number of articles discussing construction and operation of apparatus for charging furnaces of various systems, electromagnets, crane trucks, etc.

Mounted on Trucks. The Truck with the Giant Arm. Commercial Vehicle, vol. 25, no. 8, Nov. 1921, pp. 30-31, 4 figs. Universal crane, mounted on different trucks, speeds up all types of loading and gives greater flexibility in maneuvering into position.

CRANKSHAFTS

Grinding. Crankshaft Grinding. Eng. Production, vol. 3, no. 58, Nov. 10, 1921, pp. 447-450, 11 figs. Notes on special machines and attachments.

CUTTING METALS

Acetylene Jet-Cutting Machines. Economy in Metal Cutting. Eng. & Indus. Management, vol. 6, no. 20, Nov. 17, 1921, pp. 565–566, 2 figs. Describes Godfrey acetylene jet-cutting machine and its economic advantages.

Oxy-Hydrogen Cutting. Effect of Oxy-Hydrogen. Cutting on Locomotive Rods, Arthur F. Pitkin. Am. Mach., vol. 55, no. 24, Dec. 15, 1921, pp. 964–965, 11 figs. Unusual examples of rapid cutting together with data as to its effect on steel used in locomotive rods.

D

DIE CASTINGS

Design and Use. Die Castings and Their Use in Industry, C. T. Roder. Iron Age, vol. 108, no. 22, Dec. 1, 1921, pp. 1409–1411. Their relation to consumers of sand or malleable castings. Dies and their construction. Designing of castings.

DIESEL ENGINES

Ansaldo-San Giorgio. 300-Hp. Two-Cycle Diesel Engine. Engineering, vol. 112, no. 2917, Nov. 25, 1921, pp. 721–722, 10 figs. on supp. plate. Describes new series of engines built by Ansaldo-San Giorgio of Turin and Spezzia, Italy, intended primarily for industrial purposes. Results of tests with two-stroke, single-acting engine with three vertical cylinders.

Beardmore-Tosi. Trials of the Beardmore-Tosi Diesel Engine. Engineer, vol. 132, no. 3437, Nov. 11, 1921, pp. 508–510, 12 figs. one on p. 512. Results of trial are presented. Beardmore-Tosi engine, salient features of which are described, is said to mark distinct advance in four-cycle engine construction. See also Shipbldg. & Shipg. Rec., vol. 18, no. 19, Nov. 10, 1921, pp. 605–606, 3 figs. on pp. 600–601.

Compressorless. A Compressorless Diesel Engine. Power Plant Eng., vol. 25, no. 23, Dec. 1, 1921, pp. 1146–1147, 2 figs. Fuel injected without air, under pump pressure; gradual combustion at constant pressure; air compressed by lower end of piston; crosshead to take connecting-rod thrust.

Electricity Supply and. The Function of the Heavy Oil Engine in Connexion with the General Supply of Electricity, Geoffrey Porter. Gas & Oil Power, vol. 17, no. 194, Nov. 3, 1921, pp. 22–24, 2 figs. Discusses oil fuels, Diesel engine design, especially the Still engine, and advantages of heavy-oil engines based on comparative figures. From paper read before Diesel Engine Users' Assn.

Fishing Boats. Engines for Fishing Boats (Le moteurs de bateaux de pêche), Edmond Marcotte, La Technique Moderne, vol. 13, no. 7, July 1921, pp. 298–305, 9 figs. Describes various types of semi-Diesel and Diesel engines.

German Submarine. The Augsburg Ten-Cylinder Four-Stroke-Cycle U-Boat Diesel Engine, John L. Bogert. Power, vol. 54, no. 24, Dec. 13, 1921, pp. 932–933, 2 figs. Characteristics of the Augsburg 3000-hp. high-speed engine designed by I. Lauster, used on German submarines.

Sulzer. The New Sulzer Diesel Engine, A. P. Chalkley. Mar. Eng., vol. 26, no. 11, Nov. 1921, pp. 815–816, 2 figs. Describes new Sulzer marine Diesel engine with turbo-scavenging; 1,350 b.hp. at 95 r.p.m.; built by Winterthur works and being installed in a 9,000-ton deadweight motorship.

DISABLED MEN

Training of. On Behalf of the Industrial Disabled, Gerald A. Boate. Indus. Management, vol. 62, no. 6, Dec. 1921, pp. 345–352, 2 figs. Includes alphabetical list of occupations in which disabled men have been retrained. Scientific selection of suitable occupations for disabled men.

DRAWINGS

Production and. Drawings and Production. Eng. Production, vol. 3, no. 62, Dec. 8, 1921, pp. 533–536. Discussion of Albert F. Guyler's paper with above title read before Instn. Production Engrs.

Suggestions for Making. Drawings and Production. Albert F. Guyler. Eng. Production, vol. 3, no. 61, Dec. 1, 1921, pp. 509–513, 13 figs. Suggestions for the making of drawings. Paper presented before Instn. Production Engrs.

DRILLING MACHINES

Radial. Centralized Control Radial Drilling Machine Machinery (Lond.), vol. 19, no. 477, Nov. 17, 1921, pp. 197–202, 8 figs. A new tool in which all the means of control are grouped together near working position of operator.

Recent Developments. Recent Machine-Tool Developments—XXIII, Joseph Horner. Engineering, vol. 112, no. 2919, Dec. 9, 1921, pp. 780–783, 11 figs. Deals with different types of drilling machines.

Sensitive. A New Sensitive Drilling Machine. Eng. Production, vol. 3, no. 61, Dec. 1, 1921, p. 523, 1 fig. Describes machine designed by Adept Eng. Co., Birmingham, England. Work is held in vice of special construction which trips up to diameter of 3 in.

DROP FORGING

Modern Practice. Modern Drop forging Practice, Fred R. Daniels. Machy. (N. Y.), vol. 28, no. 4, Dec. 1921, pp. 308–312, 7 figs. Notes on trimming forgings; forging heats. Typical examples of drop-forging work.

E

ECONOMIZERS

Feedwater Heaters and. The Selection of Economizers and Feed-Water for Municipal Power-Plants, W. F. Schaphorst. Am. City, vol. 25, no. 6, Dec. 1921, pp. 489–493, 4 figs. Discusses operation of economizers and two types of feedwater heaters.

EDUCATION, ENGINEERING

Early Training. The Education of Engineers, E. A. Allcut. Eng. & Indus. Management, vol. 6, no. 22, Dec. 1, 1921, pp. 633–637. Refers to lack of coordination in connection with early training of engineers and points out discrepancies (starting at elementary schools) with view to their ultimate disappearance or modification.

ELECTRIC FURNACES

Gray-Iron Castings. Electric-Furnace Casting in Germany (Elektroofenguss in Deutschland), H. Kölla. Giesserei-Zeitung, vol. 18, no. 28, Oct. 18, 1921, pp. 379–381. Enumerates its advantages for production of gray-iron casting.

Melting and Refining. The Electric Furnace in Melting and Refining, John B. C. Kershaw. Electrician, vol. 87, no. 2270, Nov. 18, 1921, pp. 636–639, 5 figs. Annual review of developments, including modern tendencies in electric-furnace design, the Soderberg electrode, and the Russ electric arc furnace.

Resistance. New Electric Resistance Furnaces for Heat Treating Steel (Nouveaux fours électriques a résistance pour le traitement thermique de l'acier). L'Industrie Électrique, vol. 30, no. 705, Nov. 10, 1921, pp. 405–407, 4 figs. Describes vertical furnace and horizontal continuous furnace developed during war.

Smelting. Smelting Iron Ore Electrically, Frank Hodson. Iron Trade Rev., vol. 69, no. 23, Dec. 8, 1921, pp. 1492–1493. Points out that inexperience and inadequate financing have been responsible for failure of many efforts to place direct processes of steelmaking on practical basis.

ELECTRIC LOCOMOTIVES

Design. Selecting Designs for Electric Locomotives, A. W. Gibbs. Ry. Age, vol. 71, nos. 21 and 22, Nov. 19 and 26, 1921, pp. 987–989, 4 figs. and pp. 1057–1060, 15 figs. Nov. 19: Describes methods used for testing locomotive and discusses electric locomotive drives. Nov. 26: Tests indicate that non-symmetrical wheel arrangement is essential for best performance. (Abstract). Paper read before Franklin Inst.

Freight. Electric Freight-Train Locomotives (Elektrische Güterzuglokomotiven), Karl Trautvetter. Fördertechnik u. Frachtverkehr, vol. 14, nos. 21 and 22, Oct. 14 and 28, 1921, pp. 259–261 and 281–283. 6 figs. Discusses different German types.

Storage-Battery. Storage-Battery Locomotives in Metal Mines, E. V. Daveler and R. E. Renz. Min. & Sci. Press, vol. 123, no. 22, Nov. 26, 1921, pp. 751–752. Describes experience in Butte & Superior mine; provisions for safety; care and service of locomotives. Paper read before Nat. Safety Congress.

ELECTRIC PLANTS

Blackburn, England. The New Blackburn Power Station. Tramway & Ry. World, vol. 50, no. 25, Nov. 17, 1921, pp. 261–264, 8 figs. Describes equipment; two 10,000-kw. turbo-alternators, coal and ash-handling plant, boiler plant, switch gear, etc.

Buenos Aires. The "Dock Sud" Power Station in Buenos Aires, E. Hayn. Eng. Progress, vol., 2, no. 11, Nov. 1921, pp. 247–251, 7 figs. Position and general plan; coal supply; boiler house and engine plant; supply of cooling water; switch gear house.

Hartford Electric Light Co. The Hartford Electric Light Company's South Meadow Station. Power, vol. 54, no. 23, Dec. 6, 1921, pp. 872–882, 14 figs. Equipment arrangement particularly adapted to operating convenience. Plant laid out for 130,000 kw. in five units. Turbine's guaranteed water rate 10.1 lb. per kw-hr. Closed system of generator cooling. Boiler operation centered in boiler-control room.

Industrial Works. A Modern Works Power Plant. Eng. Production, vol. 3, no. 59, Nov. 17, 1921, pp. 469–474, 12 figs. Describes plant installed by Marshall Sons & Co., Ltd. to serve their various works at Gainsborough.

Outdoor Stations. Outdoor Stations (Les sous-stations exterieures), Leon Drin. Révue Générale de l'Électricité, vol. 10, no. 20, Nov. 19, 1921, pp. 717–728, 27 figs. Describes American stations at Tacoma, Newark, N. J., Hastings, and Minneapolis, also some French stations, and their arrangement.

Runcorn, England. New Electric Power Station at Runcorn. Engineer, vol. 132, no. 3440, Dec. 2, 1921, pp. 584–588, 13 figs. partly on p. 596. Site is laid out with view to ultimate output of 100,000 kw. and first installation comprises two 12,500-kw. Parsons turbo-generators supplied with steam from Babcock & Wilcox marine-type water-tube boilers. Supply is on three-phase a.c. system at 440 volts for power and on single-phase a.c. system at 250 volts for lighting, long-distance transmission being carried out at 33,000 volts and short-distance at 6000 and 3000 volts.

Sheffield, England. Electricity Supply in Sheffield. Electrician, vol. 87, no. 2268, Nov. 4, 1921, pp. 566–570, 7 figs. Describes new Blackburn Meadows station; coal and ash handling, boiler house, economizers, feed pumps, generators (four three-phase 50-cycle 6,600 volt two at 1,500 and two at 3,000 r.p.m.), and auxiliaries. See also Elec. Rev. (Lond.), vol. 89, nos. 2293 and 2294, Nov. 4 and 11, 1921, pp. 605–608 and 628–630, 13 figs.; also Eng. & Indus. Management, vol. 6, no. 22, Dec. 1, 1921, pp. 641–643, 4 figs.

Unit Costs. Unit Costs of New Bedford Generating Station. Elec. World, vol. 78, no. 22, Nov. 26, 1921, pp. 1072–1073, 1 fig. Discusses economical construction and efficient operation of Cannon Street station of Edison Gas & Elec. Light Co. and gives analysis of operating and construction costs.

ELECTRIC WELDING

Science of. The Science of Electric Welding, W. E. Ruder. Jl. Franklin Inst., vol. 192, no. 5, Nov. 1921, pp. 561–583, 24 figs. Notes on carbon electrode arc welding; metallic arc process; metallography of welds; metal transfer; electrodes; reliability of welded joints; electrical characteristics and equipment; automatic arc welding.

ELECTRON METAL

See MAGNESIUM ALLOYS.

ELEVATED RAILWAYS

Hamburg, Germany. Ten Years of the Hamburg Elevated Railway, Wilhelm Mattersdorff. Elec. Ry. Jl., vol. 58, no. 23, Dec. 3, 1921, pp. 879–985, 16 figs. Describes improvements made in recent years and gives operating data.

ELEVATORS

Interlocks, Survey of. Results of a Survey of Elevator Interlocks and an Analysis of Elevator Accident Statistics, C. E. Oakes and J. A. Dickinson. U. S. Bur. Standards Technologic Papers, no. 202, Oct. 17, 1921, 30 pp. Gives results of field survey of several thousand elevator landings equipped with various types of mechanical and electromechanical interlocks and contact devices. Survey was conducted in connection with preparation of elevator safety code in coöperation with engineers of Am. Soc. Mech. Engrs. Statistics show that 73.8 per cent of all fatal accidents might be prevented by well-designed interlocks.

Power for. Continuous Motors and Pneumatic Gear for High-Power Machinery (Durchlaufender Motor und Druckluftsteuerung für Arbeitsmaschinen grosser Leistung), Franz Jordan. Fördertechnik u. Frachtverkehr, vol. 14, no. 22, Oct. 28, 1921, pp. 271–274, 6 figs. Advantages of continuously over intermittently operating motors for elevators, cranes, etc., are enumerated.

EMPLOYMENT

Continuous, Problem of. The Engineering Approach to the Problem of Continuous Employment, Richard A. Feiss. Bul. Taylor Soc., vol. 6, no. 5, Oct. 1921, pp. 187–194. Deals with problems and importance of stabilization of employment.

EMPLOYMENT MANAGEMENT

Trade Tests. The Value of the Trade Test in Industry, Russell J. Waldo. Management Eng., vol. 1, no. 6, Dec. 1921, pp. 351–357, 7 figs. Shows parts of typical trade tests used by writer with unusual success.

ENGINEERS

Business Methods. Business Methods of European Engineers Compared with Those of American Engineers, Axel Malm. Jl. Engrs.' Club Phila., vol. 38–11, no. 203, Nov. 1921, pp. 389–391. Discusses salesmanship, advertising methods and education of foreign and American engineers.

Training. Training the Engineer for Industrial and Social Service. Eng. News-Rec., vol. 87, no. 24, Dec. 15, 1921, pp. 979–981. Two engineering educators discuss professional and non-professional opportunities of the young engineer and length of course justified in preparing him for service. Projecting Professional Ideas Into Business, by Frederic Bass; Visioning the Opportunity of the Engineer, Hale Sutherland.

ENGINEHOUSES

Cold-Climate. Novel Engine Facilities for a Cold Climate. Ry. Age, vol. 71, no. 22, Nov. 26, 1921, pp. 1049–1051, 2 figs. Describes rectangular enginehouse containing turntable, at Hoornepayne, Ont., constructed by Can. Nat. Ry. Co.

F

FACTORIES

Efficiency and Fuel Consumption. Efficiency and Fuel Consumption of Factory Plants (Wirkungsgrad und Brennstoffverbrauch von Fabrikanlagen), Karl Meller. Werkstattstechnik, vol. 15, no. 19, Oct. 1, 1921, pp. 565–575, 18 figs. Investigation shows present efficiency of German plants averages only 30 per cent. Study of conditions on which efficiency depends and measures to be adopted for increasing efficiency and thereby reducing consumption of coal.

FACTORY MANAGEMENT

See INDUSTRIAL MANAGEMENT.

FANS, CENTRIFUGAL

Design. The Design and Construction of Fans—XIII and XIV, F. G. Whipp. Mech. World, vol. 70, nos. 1818 and 1822, Nov. 4, and Dec. 2, 1921, pp. 370–372 and 440–441, 2 figs. Discusses cased fans and calculation of area and pressure; gives table of losses due to friction, design and calculation.

Molding and Machining. Making Centrifugal Fans, G. W. Brown. Machinery (Lond.), vol. 19, no. 479, Dec. 1, 1921, pp. 261–263, 8 figs. Describes molding and machining operations.

FATIGUE

Industrial. Methods of Reducing Fatigue in the Tool Rooms, F. B. and L. M. Gilbreth. Can. Machy., vol. 26, no. 21, Nov. 24, 1921, pp. 33 and 35, 2 figs. Discusses orderly arrangement of tools, shelves, light, etc. From paper read before Soc. Industrial Engrs.

Safety Work and. Fatigue Study. A First Step in Safety Work, Frank B. and L. M. Gilbreth. Eng. & Indus. Management, vol. 6, no. 20, Nov. 17, 1921, pp. 537–538. Authors show how fatigue can prove most useful in safety work, and that same methods and devices at present employed in factories and offices can be used effectively to do both types of work.

FLIGHT

Soaring. The Second Rhön Soaring Flight Contest (Der zweite Rhön-Wettbewerb), Werner v. Langsdorff. Luftfahrt, vol. 25, no. 9, Sept. 1921, pp. 151–156, 13 figs. Part I: Account of flight performances and description of participating machines. Part II: Technical remarks, by Roland Eisenlohr.

FLOORS

Flat-Slab. Calculation of Flat-Slab Floors (Zur Berechnung der Pilzdecke), K. Hruban. Beton u. Eisen, vol. 20, nos. 16 and 17–18, Oct. 5 and Nov. 4, 1921, pp. 187–188 and 200–202, 8 figs. Investigation of calculations heretofore used and description of new method in which variability of height of plate is taken into consideration.

FLOW IN PIPES

Hot Gases. Flow of Hot Gases in Pipes (Expériences très simples au sujet des mouvements des gaz chauds dans des tuyaux), J. Seigle. Révue de l'Industrie Minerale, no. 19, Oct. 1, 1921, pp. 607–611, 10 figs. Describes experiments in connection with circulation of hot gases and smoke in furnaces.

FLOW OF STEAM

Nozzles. Note on the Flow of Air and Steam in Nozzles, Gerald Stoney and Norman Elce. Engineering, vol. 112, no. 2918, Dec. 2, 1921, pp. 750–751. Notes on discharge coefficients which afford evidence that no condensation takes place before throat with wet or saturated steam, and that saturated steam acts down to throat as a perfect gas with adiabatic-index of 1.3.

FLUIDS

Properties at Critical Point. Theoretical Study of the Properties of Fluids at About Their Critical Points (Étude théorique des propriétés des fluides au voisinage du point critique), G. Bruhat. Journal de Physique et le Radium, vol. 2, no. 10, Oct. 1921, pp. 303–316, 1 fig. Mathematical rendering of the hypothesis of the continuity of the liquid and gaseous states and properties defining critical point; etc.

FLUE-GAS ANALYSIS

Apparatus. Improvements in Flue-Gas Investigating Apparatus (Neuerungen an Rauchgasuntersuchungsapparaten), H. v. Ihering. Zeit. für Dampfkessel u. Maschinenbetrieb, vol. 44, nos. 37 and 38, Sept. 16 and 23, 1921, pp. 291–293 and 299–301, 9 figs. Details and experiences with flue-gas testing apparatus known as Ranarex, and the Moeller-Gerdien flue-gas analyzer constructed by Siemens-Schuckert Works.

Solid and Liquid Fuels. Flue-Gas Compositions for Solid and Liquid Fuels (Rauchgaszusammensetzungen für feste und flüssige Brennstoffe), E. Kraemer. Feuerungstechnik, vol. 10, nos. 1, 3 and 4, Oct. 1, Nov. 1 and 15, 1921, pp. 3–6, 21–25 and 34–37, 7 figs. Charts are developed for rapid testing of flue-gas analyses for fuels, especially coal of variable composition.

FLYING BOATS

Dornier. The Dornier "Dragon Fly" Flying Boat. Flight, vol. 13, no. 42, Oct. 20, 1921, pp. 685–686, 6 figs. Small, low-powered, three-seater monoplane; 50–60-hp. Siemens-Halske engine, 5-cylinder radial air-cooled; almost entirely constructed of metal, especially duralumin. Gives data.

FOREMEN

Training of. How to Educate Foremen, V. M. Palmer. Indus. Management, vol. 62, no. 6, Dec. 1921, pp. 321–324. Importance of giving them systematic training and method of accomplishing this.

The Foreman's Place in Industry, Ralph W. Immel. Management Eng., vol. 1, no. 6, Dec. 1921, pp. 340–342, 2 figs. Author claims that object should be not to educate foreman, but to get him to apply knowledge he already possesses. Shows two types of form used by foreman for job analysis.

FORGING

Flow of Metal. The Flow of Metal During Forging, Harold F. Massey. Mech. World, vol. 70, nos. 1820, 1821, and 1822, Nov. 18, 25 and Dec. 2, 1921, pp. 408–410, 424–425 and 444–447, 33 figs. Results of a number of experiments, particularly to study the relation between the action of forging by pressure and by blows. Paper read before Manchester Assn. of Engrs.

FOUNDRIES

Charging Platform. Charging Floor with Undercover Storage, Edwin A. Hunger. Iron Age, vol. 108, no. 23, Dec. 8, 1921, pp. 1459–1462, 7 figs. Details of new foundry and machine shop of Duplex Printing Press Co., Battle Creek, Mich. Notable feature is big charging platform, entirely under cover, with storage capacity for 5000 tons of metal and ten carloads of coke at one time. Raw materials unloaded in single operations. Core making expedited with special cement boxes.

Conveyors for. Decreasing Foundry Costs Through the Mechanical Handling of Materials, J. M. Macrae. Management Eng., vol. 1, no. 5, Nov. 1921, pp. 257–259, 3 figs. Describes application of complete conveyor system installed in the Kelsey Wheel Co. foundry, Detroit, Mich.

Malleable-Iron. The Malleable Iron Foundry, Its Organization (La fonderie de fonte malléable, son organisation), Christian Kluytmans. La Fonderie Moderne, no. 9, Sept. 1921, pp. 241–253, 11 figs. Gives general plan for foundry and describes the various operations with samples of record cards used for routing work.

Material-Handling Equipment. Solves Material Handling Problems in Design of New Foundry, H. R. Simonds. Iron Trade Rev., vol. 69, no. 21, Dec. 15, 1921, pp. 1545–1549, 10 figs. Electrically controlled cars for raw materials, storage-battery lift trucks for ladles and castings, and monorail system speed operations in new casting plant in Springfield, Mass. Molding floor routine is flexible. Wood block floor used in all operating departments.

Systematizing Production. Systemising Foundry Production, Hubert Bentley. Eng. & Indus. Management, vol. 6, no. 22, Dec. 1, 1921, pp. 631–632, 2 figs. Describes efficient system capable of general application in foundry. Deals with regulation of supply of castings, method of ordering storage, and recording of work in hand.

FOUNDRY PRACTICE

Metal Casting. Problems Involved in Casting Metal, Thomas Turner. Foundry, vol. 49, no. 3, Dec. 1, 1921, pp. 926–933, 6 figs. With good foundry practice sound castings can be obtained from any metal provided there are no reactions which lead to formation and evolution of gas. (Abstract.) Paper read before Inst. of Metals.

FUELS

Economy. A Few Notes on the Fuel Economy Institute (Eenige korte medeelingen over het Instituut voor Brandstoffeneconomie), F. C. J. M. Wirtz. Ingenieur, vol. 36, no. 46, Nov. 12, 1921, pp. 905–907. Reviews similar organizations in other countries and describes scope of Dutch Institute.

Research. Fuel Research Developments, C. F. Kettering. Jl. Soc. Automotive Engrs., vol. 9, no. 5, Nov. 1921, pp. 291–296 and 343–344, 15 figs. Discusses multi-cylinder distribution and chemical constitution of mixtures, anti-knock substances, ignition point, future fuel research, etc.

Sawdust. Sawdust Burned with Aid of Steam Jets. Power, vol. 54, no. 24, Dec. 13, 1921, pp. 914–917, 3 figs. Large industrial plant at Cleveland, Ohio, burns both sawdust and coal under same boilers. Automatic control speeds up stokers when sawdust supply becomes low.

Smokeless. Low Temperature Carbonisation. Eng. & Indus. Management, vol. 6, no. 16, Oct. 20, 1921, p. 445. Describes new retorts patented by Low Temperature Carbonisation, Ltd., Baruch, England, by means of which, it is claimed, production of smokeless fuel, "coalite," together with all valuable by-products, is now a commercial proposition.

[See also PULVERIZED COAL.]

FURNACES, BOILER

Gas-Fired. The Continuous Thermotechnical Control of Gas Firings in Metallurgical Plants (Die fortlaufende wärmetechnische Ueberwachung der Gasfeuerungen in Hüttenbetrieben), Hermann Wolf. Stahl u. Eisen, vol. 41, no. 45, Nov. 10, 1921, pp. 1611–1614, 5 figs. Details of two measuring houses and equipment, one, for continuous control of boiler plant and the other for control of blast supply.

Heat Conservation. Thermotechnology of Boiler Furnaces (Wärmetechnisches von Dampfkesselfeuerungen), H. Schulte. Zeit. für Dampfkessel u. Maschinenbetrieb, vol. 44, no. 40, Oct. 7, 1921, pp. 319–324, 4 figs. Deals with use of low-grade fuels; mechanical draft; furnace losses; mechanical stokers; traveling grates, etc.

Lining. Lining Fire Boxes With Refractory Brick (Revestimiento de hogares con ladrillos refractarios), James F. Hobart. Ingenieria Internacional, vol. 6, no. 6, Dec. 1921, pp. 354–356, 4 figs. Discusses lining of various kinds of boiler furnaces.

Turbine Patent. The Turbine Patent Furnace. Eng. Production, vol. 3, no. 60, Nov. 24, 1921, pp. 489–490, 4 figs. Details of forced-draft unit for boilers.

Wood-Waste-Fired. Novel Boiler Installation for Burning Wood Refuse, C. W. Smith. Power Plant Eng., vol. 25, no. 24, Dec. 15, 1921, pp. 1196–1197, 5 figs. Gases from separate Dutch oven furnace are conducted through tunnel to stoker furnace and boiler.

FURNACES, HEATING

Automatic Grates. Automatic Grates and Their Application in High-Temperature Combustion Chambers (Les grilles automatiques dans leurs applications aux chambres de combustion a haute température), F. Verdeaux. La Techoique Moderne, vol. 13, no. 10, Oct. 1921, pp. 414–417, 3 figs. Discusses heating furnaces in particular; relation between temperature at fire bridge and fuel consumption; operations at high temperatures.

FURNACES, HEAT-TREATING

Springs. Furnaces for Heat Treatment of Springs. Forging & Heat Treating, vol. 7, no. 11, Nov. 1921, pp. 568–572, 18 figs. Stationary and continuous furnaces; types and arrangement.

FURNACES, HOT-AIR

Testing. Air Measurement in Furnace Testing, A. C. Willard, A. P. Kratz and V. S. Day. Jl. Am. Soc. Heating & Ventilating Engrs., vol. 27, no. 8, Nov. 1921, pp. 797–812, 11 figs. Describes air-weighing plant for calibration purposes, and the Wahlen gage for measuring small air pressures.

FUSION WELDING

Steel. The Fusion Welding of Steel, S. W. Miller. Iron Trade Rev., vol. 69, nos. 21 and 22, Nov. 24 and Dec. 1, 1921, pp. 1316–1319 and 1422–1426, 17 figs. Advantages and limitations of oxy-acetylene, electric and thermit processes. Low-carbon steel best adapted to welding. (Abstract.) Paper presented at Am. Iron & Steel Inst.

G

GAGES

Circular, Allowances with. Compound Allowance Systems and the Economical Selection of Gages with Circular Allowances (Verbundpassungssysteme und wirtschaftliche Lehrenauswahl bei Rundpassungen), K. Gottwein. Werkstattstechnik, vol. 15, no. 19, Oct. 1, 1921, pp. 579–581, 21 figs. Discusses general properties of compound systems which, with comparatively few gage classes, attain many classes of fits.

Go and Not-Go. The Need of Gauging for Modern Manufacturing, A. C. Wickman. Can. Machy., vol. 26, no. 17, Oct. 27, 1921, pp. 33–36, 3 figs. Discusses limits in the tapped hole, go and not-go gages, limit of microscopic magnification.

GAS ENGINES

Manufacture. Famous British Works. Eng. Production, vol. 3, no. 58, Nov. 10, 1921, pp. 434–435, 4 figs. Describes works of the Campbell Gas Engine Co., Ltd., Kingston, Halifax.

Schneider. Notes on the Schneider Gas Engine, H. A. A. Dombrain. Electrician, vol. 87, no. 2270, Nov. 18, 1921, pp. 643–646, 4 figs. Made in four types, viz., single cylinder, twin single cylinder, tandem, and twin tandem, the last giving as high as 6,000 hp. They are all horizontal and four stroke.

Wood-Refuse Suction. 400-Hp. Wood Refuse Suction Gas Engine. Engineer, vol. 132, no. 3438, Nov. 18, 1921, p. 547, 4 figs. partly on p. 540. Details of engine to work on gas derived from producer fired with wood refuse. It has four cylinders, each 17-in. diam. by 24-in. stroke.

GAS PRODUCERS

Calculations of Gas in. Calculations Regarding Gas in Gas Generator With Steam Added to Air Blowing (Calculs comparatifs au sujet des gaz de gazogène, dans le cas d'addition de vapeur d'eau a l'air soufflé), J. Seigle. Révue de Métallurgie, vol. 18, no. 9, Sept. 1921, pp. 608–618, 7 figs. Discusses calorific power per cubic meter, calorific power of the volume of gas from 1 kg. of coal, etc.

Central. Ten Years' Experience with Central Producer Plant in the Municipal Gas Works of Vienna (10 Jahre Zentralgeneratorenbetrieb in den Wiener städtischen Gaswerken), Ernst Kaudela and Josef Pretsch. Gas- u. Wasserfach, vol. 64, no. 37, Sept. 10, 1921, pp. 601–606, 3 figs. Advantages of central producers are summarized.

Ebelmen. The Fused Ash Gas Producer (Le gazogène à fusion des cendres), A. Fichet. Le Génie Civil, vol. 79, no. 16, Oct. 15, 1921, pp. 329–332, 2 figs. Describes Ebelmen system principally, also the Rehmann system.

Lignite Briquets for. Using Lignite Briquettes in Gas Generators (Essais d'utilisation de briquettes de lignite pour le chauffage de fours à gazogène), De Groote. Chaleur et Industrie, vol. 2, no. 18, Oct. 1921, pp. 661–666. Describes favorable experiments with a battery of three Morgan generators; composition of briquettes used, heat balance, ash, composition of gas, etc.

Pulverized-Coal. Producers for Pulverized Coal (Kohlenstaubvergaser), H. Gwosdz. Zeit. für Dampfkessel u. Maschinenbetrieb, vol. 44, no. 38, Sept. 23, 1921, pp. 297–299, 2 figs. Discussion of Marconnet and Hirt types and possibilities of improvements.

GEARS

Helical. Cutting Helical Gears on Automatic Machine, H. A. Wilson. Can. Machy., vol. 26, no. 19, Nov. 10, 1921, pp. 29–33, 13 figs. Various operations on automatics, including making of stud; dust cap cutting helical gears; chart showing tools used; machine equipped with rear end threading attachment.

Herringbone. Double Helical or Herringbone Gears, Howard H. Talbot. Iron Age, vol. 108, nos. 23 and 24, Dec. 8 and 15, 1921, pp. 1469–1473 and 1531–1533, 17 figs. Dec. 8: Elements of design to combine adequate strength with smooth and continuous action and minimum of friction of contact surfaces. Dec. 15: Use of long addenda in pinion and short addenda in driven gear, to increase the "follow through."

Maag. Maag Gearing, L. J. Le Mesurier. Engineering, vol. 112, no. 2919, Dec. 9, 1921, pp. 801–805, 20 figs. Describes system of gearing and methods of production developed by Maag Gear Co., Zurich, Switzerland, with which means have been found which enable straight-tooth spur gears to be employed successfully under conditions demanding highest possible peripheral speeds and loads per unit width of tooth. Describes entirely novel grinding process. (Abstract.) Paper read before North-East Coast Instn. Engrs. & Shipbuilders.

GRINDING

Milling vs. Milling Versus Grinding (Fräsen oder

Schleifen-), Carl Krug. Werkstattstechnik, vol. 15, no. 19, Oct. 1, 1921, pp. 575–576. Presents table showing relative working conditions with milling and grinding machines, showing economy of latter.

Steel Billet. Modern Method of Steel Billet Grinding, R. H. Cannon. Forging & Heat Treating, vol. 7, no. 11, Nov. 1921, pp. 557–559, 3 figs. Advantages of grinding over chipping in relation to wheel cost, labor cost and overhead. Making grinding wheel test

H

HANDLING MATERIALS

Factories. An Organized Transportation Department, John A. MacCrea. Management Eng., vol. 1, no. 6, Dec. 1921, pp. 327–329, 4 figs. Describes briefly organization and principal features of operation of department for moving of material.

Trucks as Conveyors. Making the Truck an Asset in Management, Edward H. Tingley. Management Eng., vol. 1, no. 5, Nov. 1921, pp. 267–271, 9 figs. How special types may be used to save floor space, provide effective storage and minimize moving time between operations.

Waste Elimination. Material Handling an Important Factor in the Elimination of Industrial Waste, H. V. Coes. Mech. Eng., vol. 43, no. 12, Dec. 1921, pp. 803–804 and 825. Points out opportunities in almost every branch of industry to reduce large wastes in material handling. Examples of savings effected, and how to arrive at best method.

HANGARS

German Airship. Large German Airship Stations, J. Sabatier. Aerial Age Weekly, vol. 14, no. 6, Oct. 17, 1921, pp. 128–130. Discusses general plans, construction details, hangar accessories, maneuvering fields, hydrogen works, etc. Translated from L'Aeronautique.

HARDNESS

Measurement of Steel Balls. Schleroscope Hardness of Steel Balls, Arthur L. Collins. Iron Age, vol. 108, no. 22, Dec. 1, 1921, pp. 1391–1393, 5 figs. Widely varying results on different sizes. Explanation of cause and suggested remedy.

Testing. The Hardness Testing of Metals. Eng. Production, vol. 3, no. 58, Nov. 10, 1921, pp. 436–440, 11 figs. Discussion of modern methods. (Abstract). Progress report of Committee of Eng. Div. of U. S. Nat. Research Council.

The Use of the Scleroscope on Light Specimens of Metals, Fred S. Tritton. Metal Industry (Lond.), vol. 19, no. 19, Nov. 4, 1921, pp. 361–364, 4 figs. Describes experiments undertaken to find out whether errors existed when using ordinary methods of support, and, if so, to find some method of support that would eliminate them.

HEAT TRANSMISSION

Air Spaces. Air Space Transmission, Percy Nicholls. Jl. Am. Soc. Heating & Ventilating Engrs., vol. 27, no. 8, Nov. 1921, pp. 783–790, 3 figs. Includes abstract of paper by H. C. Dickinson and M. S. Van Dusen on the testing of thermal insulators, and presents table prepared by Bur. of Standards, separating values for radiation and convection.

HEATING, ELECTRIC

Development, Switzerland. The Development of Electric Heating in Switzerland (Die Entwicklung der elektrischen Heizung in der Schweiz). Gesundheits-Ingenieur, special no., July 1921, pp. 18–27, 15 figs. Describes arrangements developed by Sulzer Bros., Winterthur, Switzerland, in reconstruction of existing hot-water installations, steam and hot-water central-heating plants for use of electricity.

Hot-Water. The Electric Pumping Hot-Water Heating System in the Repair Shop for Electric Locomotives of the Swiss Federal Railway in Bellinzona (Die elektrische Pumpen-Warmwasserheizung in der Reparaturwerkstätte fur elektrische Lokomotiven der Schweiz. Bundesbahnen, in Bellinzona). Schweiz. Elektrotechnischer Verein Bul., vol. 12, no. 10, Oct. 1921, pp. 270–274, 4 figs. Describes electric heating installation believed to be largest of its kind.

HEATING, FACTORY

Ventilation and. Heating and Ventilation of Factories, H. H. Angus. Contract Rec., vol. 35, no. 50, Dec. 14, 1921, pp. 1085–1088. General outline of principles involved and methods adopted to maintain satisfactory working temperatures and atmospheric conditions. Paper before Toronto Branch Am.Soc.Mech.Engrs.

HEATING, STEAM

Central-Station. The Economy of Large Central Heating Plants (Ueber die Wirtschaftlichkeit grosser Fernheizungsanlagen). Gesundheits-Ingenieur, special no., July 1921, pp. 27–32, 8 figs. Based on operating results in two Westphalian provincial sanitariums.

HELIUM

Airships. Helium for Airships. Aviation, vol. 11, no. 22, Nov. 28, 1921, p. 635. Discusses available supply, cost of production, repurification plant, etc.

HYDRAULIC TURBINES

Breakdown. Investigation of Breakdown of 30,000-Kw. Turbine. Power, vol. 54, no. 21, Nov. 22, 1921, pp. 788–793, 13 figs. Account of accident in Schuylkill plant of Philadelphia Elec. Co. and conclusions from investigation. Points out that abrupt changes of section and formation of sharp angles in design of bucket wheels should be avoided.

Design. Certain Features Relating to Hydraulic Turbine Design and Settings, E. W. Burbank. Proc. La. Eng. Soc., vol. 7, no. 4, Aug. 1921, pp. 150–173, 8 figs. Discusses formulas and terms used, reaction and impulse types of turbines and their operation.

Efficiency. Influence of Turbine Efficiency on Yield of Hydroelectric Plants (Einfluss des Turbinen-Wirkungsgrades auf den Ertrag von Wasserkraftanlagen), H. Leiner. Elektrotechnische Zeit., vol. 42, no. 39, Sept. 29, 1921, pp. 1089–1093. Equations are developed for determination of efficiency of turbines from economical and technical viewpoint.

Impulse. Largest Impulse Turbine Units in Caribou Station, W. M. White. Power, vol. 54, no. 24, Dec. 13, 1921, pp. 923–926, 7 figs. Two of largest impulse-wheel-driven units in world, rated at 30,000 hp. each and operating under 1008-ft. heat at 171 r.p.m. have been installed. Unit consists of two independent wheels, one on either side of generator.

Sand-Removing Plant. Wear in Hydraulic Turbines and How to Avoid It (L'usure des turbines hydrauliques, ses consequences et les moyens d'y parer), H. Dufour. Bulletin Technique de la Suisse Romande, vol. 47, no. 22, Oct. 29, 1921, pp. 253–256, 6 figs. Describes sand-removing plant at Monthey works of Societé pour l'Industrie Chimique à Bâle.

HYDROELECTRIC DEVELOPMENTS

Dutch East Indies. Water Power Construction Work and Prospects in the Dutch East Indies (Verrichtingen en verwachtingen op waterkrachtgebied in Ned.-Indië), A. Groothoff. Ingenieur, vol. 36, no. 48, Nov. 26, 1921, pp. 945–953, 17 figs. Discusses resources and plants in Java, Sumatra, Borneo and Celebes.

Queenston-Chippawa. The Chippawa-Queenston Power Canal. Can. Engr., vol. 41, no. 23, Dec. 8, 1921, pp. 1 and 10, 6 figs. Big Ontario power development practically completed. Canal is 12$^1/_2$ mi. long with max. depth of 145 ft.; available gross head, 315 ft.; width of concrete section, 48 ft.; depth of water, 35–40 ft.; total earth excavation, 13,299,000 cu. yd.; total rock excavation, 4,182,000 cu. yd.; max. capacity of each turbine, 60,000 hp.; total weight of each complete generating unit, 1,853,000 lb.

St. Lawrence River. Hydro Report on St. Lawrence River. Can. Engr., vol. 41, nos. 21, 22, 23 and 24, Nov. 24, Dec. 1, 8 and 15, 1921, pp. 1, 4–5; pp. 1,4, 5, 9 and 10, 5 figs.; pp. 4–5; and 9–10. Suggests three alternative schemes for power development and gives cost of each. Study of physical conditions. Ontario Hydroelectric Commission's engineering report to Int. Joint Commission.

The St. Lawrence Power Development. Can. Engr., vol. 41, no. 22, Dec. 1, 1921, pp. 1, 10, 11 and 12, 4 figs. Salient features of report by Hugh L. Cooper to Int. Joint Commission on navigation and power in St. Lawrence River. Recommends Croil Island as site for main dam and power plant.

Seattle, Wash. Progress on the Skagit River Power Project. Eng. News-Rec., vol. 87, no. 23, Dec. 8, 1921, pp. 948–949, 3 figs. 23-mi. railroad and construction power plant completed in Seattle. Work on 2-mi. main tunnel is under way.

World. Hydro-Electric Developments—II and III, F. Rowlinson. Beama, vol. 9, nos. 4 and 5, Oct. and Nov. 1921, pp. 351–359 and 451–458, 3 figs. Oct.: Discusses undertakings in Scandinavia, Canada, Australia, India, Switzerland, Spain, Italy, etc. Nov.: Developments in Austria, United States, Sweden and Formosa.

HYDROELECTRIC PLANTS

Lausanne, Switzerland. Electric Plants of the Town of Lausanne (Les installations électriques de la ville de Lausanne), M. Cauderay. Bulletin Technique de la Suisse Romande, vol. 47, nos. 19 and 21, Sept. 17 and Oct. 15, 1921, pp. 217–223 and 241–248, 16 figs. Describes reservoirs, conduits, canals, turbines, electrical installations, etc., in connection with hydroelectric plant and its enlargement.

220,000-Volt. First 220,000-Volt Station Completed. Elec. World, vol. 78, no. 23, Dec. 3, 1921, pp. 1115–1119, 12 figs. Describes Big Creek No. 8 Station built by Southern Cal. Edison Co.; has 22,500 kw. vertical reaction turbine; lines are operated at 150,000 volts and will be at 220,000 volts ultimately.

I

INDUSTRIAL MANAGEMENT

Assembling Methods. Saving Time in Assembling, Albert A. Dowd and Frank W. Curtis. Machy. (N. Y.), vol. 28, no. 4, Dec. 1921, pp. 296–300, 6 figs. Examples showing savings resulting from investigation of assembling methods.

Executive Control Charts. Comparability of Executive Control Charts, Arthur R. Burnet. Management Eng., vol. 1, no. 5, Nov. 1921, pp. 283–288, 7 figs. Fundamental requirement of the "Z" chart and how it may be secured.

Factory Investigations. How Factory Investigations Reduce Costs. Machinery (Lond.), vol. 19, no. 476, Nov. 10, 1921, pp. 149–154, 7 figs. Discusses handling of materials, inspection and salvage, manufacturing a fly-wheel pulley, savings effected by use of punch press, etc.

Financial Control. The Parallel Line of Control in Business, Frederic H. Leland. Management Eng., vol. 1, no. 6, Dec. 1921, pp. 348–350, 1 fig. Points out that there are two scales of parallel lines of business control, a major scale, which shows correctly amount of money involved in principal activities of business; and minor scale which shows money involved in greater detail than is shown on major scale.

Financial Leaks. Seven Leaks We Have Stopped, A. H. Cubberley. Factory, vol. 27, no. 6, Dec. 1921, pp. 743–747, 2 figs. Analysis of principal financial leaks and how to stop them. Practice at E. I. du Pont de Nemours Co. works.

Future of. Scientific Management—XXXIII, Henry Atkinson. Eng. & Indus. Management, vol. 6, no. 19, Nov. 10, 1921, pp. 529–531. Future of scientific management. (Concluded.)

Gantt Charts. The Gantt Chart—IV, Wallace Clark. Management Eng., vol. 1, no. 5, Nov. 1921, pp. 279–282, 3 figs. Its application to plant load.

Improved Methods. Exhibit by the Siemens-Schuckert Works of Practical Examples of Scientific Management (Die Siemens-Schuckertwerke auf der Betriebstechnischen Wanderausstellung), C. W. Drescher. Betrieb, vol. 4, nos. 1 and 2, Oct. 8 and 22, 1921, pp. 1–9 and 11–14, 16 figs. Examples of improvements of working methods by use of up-to-date tools, time and motion studies, standards for cutting tools, toolroom organization, comparison of separate and belt electric drive. Psychotechnical adaptability tests.

Managers, Training. What Constitutes a Good Manager?, N. H. Daniels. Indus. Management, vol. 62, no. 6, Dec. 1921, pp. 329–332. How a large engineering firm trains men to deal successfully with public.

Measuring Effectiveness. Measuring the Effectiveness of Management, William B. Ferguson. Management Eng., vol. 1, no. 6, Dec. 1921, pp. 335–340, 1 fig. Study of proportions management resources as: Organization 35 per cent, technical 20 per cent, utilization 45 per cent.

Planning Department. Fundamental Principles for Modern Workshop Precalculation (Unterlagen für moderne Werkstattvorkalkulation), R. Wiekop. Betrieb, vol. 4, no. 2, Oct. 22, 1921, pp. 29–39, 11 figs. Practical recommendations for job analysis. A new premium system.

Planning in Large Contract Plants, George H. Shepard. Machy. (N. Y.), vol. 28, no. 4, Dec. 1921, pp. 268–270, 1 fig. Organization of department for planning progress of work through shop.

Production Control. Humanizing Production Control, Howell B. May. Indus. Management, vol. 62, no. 6, Dec. 1921, pp. 341–344. How new spirit of team-work in industry is being put in practice. Explains idea of coöperative inter-relationship in factory for purpose of educating foremen and workers and giving ambitious ones an opportunity to advance.

Production, Fluctuation in. Applying "Moving Average" Charts to Industry, A. L. DeLeeuw. Management Eng., vol. 1, no. 6, Dec. 1921, pp. 343–348, 9 figs. Discusses fluctuation in production and how it is reduced.

Production Methods. Modern Production Methods—XXIV, W. R. Basset. Am. Mach., vol. 69, no. 23, Dec. 8, 1921, pp. 950–955, 7 figs. Setting piece rates. Points out that incentive factor is as important as securing results for wage given. Examples of rate derivation. Why piece rates should not be cut.

Productive Ways and Means, H. Darbyshire. Eng. & Indus. Management, vol. 6, no. 22, Dec. 1, 1921, pp. 618–621, 4 figs. Writer deals with number of essential details with which management and supervising staff of any industrial organization should become familiar.

Progress Department. Estimating and Handling Output of "Modifications." Eng. & Indus. Management, vol. 6, no. 21, Nov. 24, 1921, pp. 601–603. Describes progress organization of factory, where, although lines are standardized and produced upon more or less repetition basis, these lines may be modified time and again to meet specific requirements of customers.

Record Sheets. Systematizing and Control of Workshop Jobs (Systematisierung und zwangläufige Kontrolle von Werkstatt-Aufträgen), Carl Redtmann. Der praktische Maschinen-Konstrukteur, vol. 54, no. 36, Sept. 8, 1921, pp. 289–292, 8 figs. Describes record sheet system for carrying out workshop jobs used successfully in machine factory employing 400 to 500 workers.

Workpiece Record Cards (Die Operationslaufkarte), A. Roth. Betrieb, vol. 4, no. 2, Oct. 22, 1921, pp. 44–48, 9 figs. Discusses use of record sheets in machine construction on which all necessary operating data are recorded and which accompany workpiece through all operating stages until delivery into storkroom.

Records for Electrical Department. Efficient Record System for Industrial Electrical Department, J. Elmer Housley. Elec. World, vol. 78, no. 21, Nov. 19, 1921, pp. 1015–1018, 1 fig. Gives forms for motors, lamps, trucks, etc., and describes how to use them.

Simplification. Why We Invested $7,000,000 in "Simplification," Harvey S. Firestone. Factory, vol. 27, no. 6, Dec. 1921, pp. 739–743, 8 figs. Describes policy, developed into specific plan, which has eliminated manufacturing wastes, cut labor costs 20 per cent, and improved quality of product.

Storing Materials. Management Problems of the Small Factory, Ernest Cordeal. Indus. Management, vol. 62, no. 6, Dec. 1921, pp. 334–340, 7 figs. How materials are effectively handled and stored.

Toolroom Organization. Organising Tool Production. Eng. Production, vol. 3, no. 59, Nov. 17, 1921-

pp. 462–466, 13 figs. Procedure in the works drawing office and toolroom.

[See also TIME STUDY.]

INDUSTRIAL ORGANIZATION

Engineering Department. Organization of an Engineering Department. W. E. Irish. Indus. Management, vol. 62, no. 6, Dec. 1921, pp. 357–361, 1 fig. Author shows plan of organization found suitable to requirements of large steel company and gives account of its working.

Knitting Mills. The Organisation of Knitting Mills, Carle M. Bigelow. Management Eng., vol. 1, nos. 5 and 6, Nov. and Dec. 1921, pp. 261–265, 7 figs. and pp. 359–364, 6 figs. Nov.: Standardizing physical conditions. Deals with plant layout and routing. Dec.: Standardizing control of material.

INDUSTRIAL RELATIONS

Construction Industries. Development of Satisfactory Relationship Between Employer and Employe in Construction Industry, Ernst T. Trigg. Eng. & Contracting, vol. 56, no. 21, Nov. 23, 1921, pp. 479–481. (Abstract.) Paper presented before joint meeting of Acad. Political Sci. and Am. Indus. Relations Assn. See also Contract Record, vol. 35, no. 47, Nov. 23, 1921, pp. 1021–1023.

Human Factor. The Human Factor in Industry—III, Clarence H. Northcott. Indus. Management, vol. 62, no. 6, Dec. 1921, pp. 363–369. Deals with psychology, instincts and tendencies of worker.

Open-Shop Foundry. The Transition to an Open-Shop Foundry, Paul R. Ramp. Iron Age, vol. 108, no. 22, Dec. 1, 1921, pp. 1395–1398. Methods used with success in training molding-machine workers, with view to increased output.

Training Executives. Training the Industrial Relations Executive, Edward S. Cowdrick. Management Eng., vol. 1, no. 6, Dec. 1921, pp. 329–330. Notes on college courses in industrial relations.

Works Council. Industrial Democracy in Great Britain, Clarence H. Northcott. Management Eng., vol. 1, no. 5, Nov. 1921, pp. 295–297. Deals with establishment of a works council; qualifications for membership and voting, and how council is organized.

INSPECTION

Systems. Inspectors' Reports, Examples and Methods. Eng. & Indus. Management, vol. 6, no. 20, Nov. 17, 1921, pp. 570–573. Discussion of certain systems of inspection, with view to demonstrating their efficiency under given conditions.

INTERNAL-COMBUSTION ENGINES

Marine. Internal Combustion Engines in Marine Service—II, Charles Edward Lucke. Jl. Am. Soc. Mar. Draftsmen, vol. 8, no. 3, Oct. 1921, pp. 47–57, 10 figs. Compares new standards of turbine steamer and motorship machinery. Paper read before Franklin Inst.

[See also AIRPLANE ENGINES; AUTOMOBILE ENGINES; DIESEL ENGINES; GAS ENGINES; OIL ENGINES, SEMI-DIESEL ENGINES.]

IRON

Electrodeposition of. The Industrial Future of Electro-Deposited Iron, W. E. Hughes. Chem. Age (Lond.), vol. 5, no. 124, Oct. 29, 1921, pp. 521–523, 4 figs. Discusses results of research work and microscopic examination of structure of deposited iron. Sees good future for its application.

Electrolytic. Commercial Production of Electrolytic Iron, C. P. Perin and Donald Belcher. Min. & Metallurgy, no. 180, Dec. 1921, pp. 17–18, 2 figs. Describes French process consisting of electrolyzing a concentrated solution of ferrous chloride at temperature of 75 deg. cent. Anodes are of cast iron, cathode is a rotating mandrel of steel. With this process tubes and sheets of any desired gage can be made.

IRON AND STEEL

Chemical Industries, Relations to. Relations of the Iron and Steel and Chemical Industries, James M. Camp. Iron Age, vol. 108, no. 21, Nov. 24, 1921, pp. 1329–1331, 1 fig. Notes on chemicals consumed by steel makers; steel used by chemical plants; role of by-products from coke. Paper read before Am. Iron & Steel Inst.

Sweden. The Swedish Iron and Steel Industry. Raw Material, vol. 4, no. 10, Oct. 1921, pp. 344–348, 8 figs. Historical review of its development.

IRON, PIG

Calculating Foundry Value of. Calculating a Foundry Iron Value, Y. A. Dyer. Iron Age, vol. 108, no. 24, Dec. 15, 1921, pp. 1547–1548. Unit valuation of elements in foundry pig irons. Silicon, manganese and phosphorus considered as metalloids. Carbon and sulphur grouped as Fe.

L

LABOR

Classes to be Avoided. Three Classes of Labor to Avoid, H. A. Haring. Indus. Management, vol. 62, no. 6, Dec. 1921, pp. 370–373. Discusses prejudices and habits displayed by men in certain occupations, and describes effects of certain classes of employment upon individual's fitness for modern industrial work.

LATHE TOOLS

Automobile Forgings. Cost-reducing Tooling Equipments, Ralph E. Flanders. Machy. (N. Y.), vol. 28, no. 4, Dec. 1921, pp. 301–305, 13 figs. Employed for machining steering knuckles and other automobile forgings at high rate of production.

LATHES

Automatic. The Pratt & Whitney Automatic Lathe. Machy. (N. Y.), vol. 28, no. 4, Dec. 1921, pp. 282–284, 6 figs. Equipped with headstock, tailstock, magazine for holding work, and automatic work-handling and control mechanism.

Automobile Work on Turret. Automobile Production Work on Turret Lathes, Edward K. Hammond. Machy. (N. Y.), vol. 28, no. 4, Dec. 1921, pp. 261–264, 7 figs. Time-saving and cost-reducing methods developed for use in engine department of motor car plant.

Large. The Evolution of the Large Lathe. British Machine Tool Eng., vol. 1, no. 12, Nov.-Dec. 1921, pp. 413–419, 9 figs. Discusses development of T. Shanks & Co.'s type of lathes to the present 123-in. center double-bed type, which swings 18 ft. 6 in. diameter over saddles.

Turret. "Apollo" $2^{3}/_{4}$ In. Hollow Spindle Turret Lathe. Engineering, vol. 112, no. 2918, Dec. 2, 1921, pp. 758–759, 29 figs. partly on supp. plate. Details of new model of hollow-spindle or bar lathe brought out by Pollock & Macnab, Ltd., having a hollow spindle, $3^{1}/_{8}$ in. in internal diam., intended for work $2^{3}/_{4}$ in. in diam. and up to 36 in. in length. Heating of centers is $9^{1}/_{2}$ in. and length of bed 8 ft. 9 in.

LIGHTING

Industrial. Good Lighting Increases Production, J. M. Hickerson. Indus. Management, vol. 62, no. 6, Dec. 1921, pp. 325–328, 2 figs. Summary of major facts brought out by survey of industrial lighting conditions.

Illuminating Engineering: The Future Field, J. H. Asdell. Eng. & Indus. Management, vol. 6, no. 16, Oct. 20, 1921, pp. 441–444. Practical notes on planning an efficient scheme of lighting for industrial purposes, together with simple formula for calculation of illumination in general practice.

Metal-Working Plants. Lighting Metal-Working Plants to Increase Production, A. L. Powell. Elec. World, vol. 78, no. 22, Nov. 26, 1921, pp. 1069–1072, 7 figs. Proper intensities, spacings and fixtures for benches, machine tools, sheet-metal work, assembling, painting, etc.; general or "localized-general" system of illumination is satisfactory in most cases.

LIQUIDS

Combustible, Atomizers for. Atomizers for Combustible Liquids (Sui polverizzatori del combustibile liquido). L'Industria, vol. 35, no. 17, Sept. 15, 1921, pp. 389–390, 6 figs. Describes apparatus with four orifices; gives table of pressures and oil atomized.

LOCOMOTIVES

Air Tanks. Fabricating Tanks From Heavy Plate, C. E. Lester. Boiler Maker, vol. 21, no. 11, Nov. 1921, pp. 313–315, 2 figs. Air locomotive tanks built for 800 lb. pressure fitted with special heads.

Belgian. Belgian State Railway Locomotives Type 33 (Locomotives type 33 etat Belge), O. Lepersonne. Révue Universelle des Mines, vol. 11, no. 2, Oct. 15, 1921, pp. 176–181, 3 figs. A compound, four-cylinder, superheater, 2–6–2 locomotive; tractive effort 12,500 kg. Data and description.

Caledonian Railway. Recent Locomotive Practice on the Caledonian Railway, E. C. Poultney. Engineer, vol. 132, nos. 3436 and 3437, Nov. 4, and 11, 1921, pp. 474–476, and 499–500, 9 figs. partly on supp. plate and p. 501. Describes four new classes of locomotives, comprising engines for passenger and goods traffic as follows: Passenger service—outside-cylinder six-coupled, 4–6–0 type; inside-cylinder four-coupled, 4–4–0 type; outside-cylinder six-coupled side-tank engines, 4–6–2 type. Goods service—inside-cylinder six-coupled, 0–6–0 type.

Feedwater Heating. Feedwater Heaters for Locomotives (Speisewasservorwärmer), H. Gunther. Zeit. des Vereines deutscher Ingenieure, vol. 65, no. 47, Nov. 19, 1921, pp. 1205–1209, 12 figs. Describes heaters with special closing of headers for high water velocities and a live by-pass valve for prevention of cold feeding. Operating experiences with scale formation and elimination. Experimental results with new, cleaned and heavily incrusted heaters.

Feedwater Treatment. Water Treatment From an Investment Standpoint, L. F. Wilson. Ry. Rev., vol. 69, no. 19, Nov. 5, 1921, pp. 602–604. Discusses external and internal treatment of locomotive feedwater.

Fuel Consumption. The Effect of Grade on Locomotive Coal Consumption, George S. Chiles. Ry. Rev., vol. 69, no. 22, Nov. 26, 1921, pp. 715–719, 2 figs. Actual operation of modern equipment illustrates influence of ascending and descending grades.

Hornblocks, Machining. Machining Locomotive Hornblocks. Eng. Production, vol. 3, no. 58, Nov. 10, 1921, p. 451, 4 figs. Describes operation on horizontal milling machine.

Missouri Pacific R. R. New Mountain, Pacific and Switching Locomotives for the Missouri Pacific Railroad. Ry. & Locomotive Eng., vol. 34, no. 9, Sept. 1921, pp. 242–244, 3 figs. Built by American Locomotive Co. 0–6–0 type switching engines: tractive power, simple, 39,100 lb.; working pressure 100 lb. 4–8–2 mountain type engines: tractive power, simple, 53,500 lb.; working pressure, 210 lb. 4–6–2 Pacific type engines: tractive power, simple, 39,500 lb.; working pressure, 193 lb.

Modern Design. Modern Locomotive Engine Design and Construction—LXXV. Ry. Engr., vol. 42, no. 502, Nov. 1921, pp. 421–424 and 439, 3 figs. Discusses coupling-rod design and construction, coupling-rod stresses, etc.

Oil-Burning. The Lentz Hydraulic Drive for Heavy-Oil Locomotives (Das Flussigkeitsgetriebe von Lentz für Schwerölllokomotiven), H. Wittfeld. Zeit. des Vereines deutscher Ingenieure, vol. 65, no. 45, Nov. 5, 1921, pp. 1160–1163, 4 figs. Discusses efforts heretofore made for rendering internal-combustion engines for heavy oil feasible for locomotive drive with aid of the Lentz hydraulic drive; and gives operating results with trial of first heavy-oil locomotive with such drive.

Steam Production and Use. On the Question of Economic Production and Use of Steam on Locomotives, G. J. Churchward. Bul. Int. Ry. Assn., vol. 3, no. 10, Oct. 1921, pp. 1527–1538, 1 fig. Abstract of replies to questions on superheated steam, superheater engines and non-superheater engines, feedwater treating, and special arrangements, water-tube boilers, etc. Appendix describing Riegel water-tube locomotive boiler.

Steam-Turbine. An Early Steam Turbine Locomotive. Engineering, vol. 112, no. 2917, Nov. 25, 1921, p. 728, 4 figs. on p. 730. Details of Belluzzo steam-turbine locomotive constructed in 1908 by Societa Anonima Officine Meccaniche, Milan, and recently dismantled.

The Zoelly Steam-Turbine Locomotives with Use of Condensation (Zoelly-Dampfturbinen-Lokomotive mit Kondensation). Glasers Annalen, vol. 89, no. 8, Oct. 15, 1921, pp. 88–89, 2 figs. Describes steam piston locomotive built for Swiss Federal Railway. In front of smokebox two enclosed turbines are installed, one for running forward and the other for running backward. Advantages: Saving of at least 20 per cent of coal; elimination of scale formation through use of condensed feedwater, thus considerably increasing life of boiler and reducing cost of operation; insensibility of steam turbine to highly superheated steam.

Stoker-Fired. The Locomotive Stoker As An Operating Factor, Frank P. Roesch. Ry. Rev., vol. 69, no. 21, Nov. 19, 1921, pp. 685–687. How stoker-fired locomotives can be operated to obtain maximum operating efficiency with minimum expense.

Performance of the Hanna Locomotive Stoker on the Norfolk & Western Railway. Ry. & Locomotive Eng., vol. 34, no. 11, Nov. 1921, pp. 308–310, 1 fig. Describes special trial trips showing efficiency of this stoker. Particulars of firebox conditions, etc.

Superheater. Superheater Practice in American Locomotives. Boiler Maker, vol. 21, no. 11, Nov. 1921, pp. 301–305, 12 figs. Describes most successful methods developed for handling superheater work by railroads.

Transportation without Dismantling. Locomotives for Belgian State Railways. Ry. Gaz., vol. 35, no. 19, Nov. 4, 1921, pp. 690 and 697, 5 figs. partly on pp. 691–692. Describes arrangements by Armstrong, Whitworth & Co. for delivering locomotives to Belgium without dismantling for transport.

Trucks. On the Question of Bogies (Trucks), Axle and Springs of Locomotives, George Hughes. Bul. Int. Ry. Assn., vol. 3, no. 10, Oct. 1921, pp. 1589–1674, 84 figs. Includes appendixes containing tabular statements on kinds of bogies used by various companies, method of fixing springs for driving and coupled wheels, springing, cylinders, heating surfaces and particulars of two-wheel trucks.

2-8-2 Mikado. 2–8–2 Type Locomotives for the Nickel Plate. Ry. Mech. Engr., vol. 95, no. 12, Dec. 1921, pp. 737–738, 4 figs. Design based on U.S.R.A. light Mikado with improvements in details. Booster handles 22 per cent additional tonnage.

2-10-2 and Pacific Types. American Locomotives for the Philippines. Ry. Rev., vol. 69, no. 23, Dec. 3, 1921, pp. 756–769, 11 figs. Describes 2–10–2 and Pacific-type locomotives delivered by American Locomotive Co. to Manila Railroad; tractive effort 35,700 and 28,600 lb.

LUBRICATING OILS

Capillary Properties. Testing of Lubricants for Determination of Their Capillary Properties (Zur Schmierölprüfung auf die kapillaren Eigenschaften der Schmiermittel), Richard von Dallwitz-Wegner. Petroleum, vol. 17, nos. 24 and 25, Aug. 20 and Sept. 1, 1921, pp. 849–854 and 885–887, 4 figs. Demonstrates necessity, when testing oils, of investigating their capillary properties and describes apparatus therefor.

Recovery from Anthracite Tar. The Recovery of Viscous Lubricating Oils from Anthracite Tar (Gewinnung viskoser Schmieröle aus Steinkohlenteer), F. Schreiber. Zeit. für angewandte Chemie, vol. 34, no. 65, Aug. 16, pp. 425–426, 3 figs. Describes process of recovery developed and perfected in Germany during recent years, and discusses properties and economic advantages of product known as "Ess" oil, to distinguish it from other tar oils.

Removal from Condensation Water. The Removal of Oil from Water of Condensation Through Electrolysis (Die Entölung von Kondenswässern durch Elektrolyse), Fritz Hoyer. Feuerungstechnik, vol. 10, no. 4, Nov. 15, 1921, pp. 33–34. Describes process and apparatus.

LUBRICATION

Automobile Chassis. Various Methods of Chassis Lubrication, Cornelius T. Myers. Automotive Industries, vol. 45, no. 22, Dec. 1, 1921, pp. 1067–1069. Compares lubricating materials and discusses various methods and devices. Condensed from paper read before Soc. Automotive Engrs.

Prime Movers. The Lubrication of Prime Movers, C. H. Bromley. Mech. World, vol. 70, no. 1821, Nov. 25, 1921, pp. 428–429. Discusses oils for steam turbines, emulsion and sludge, Diesel-engine lubri-

cation, etc. (Abstract). Paper read before System Operators' Assn.

LUMBER

Care in Storage. The Care and Protection of Lumber in Storage, H. A. Sackett. Ry. Age, vol. 71, no. 24, Dec. 10, 1921, pp. 1133–1136, 9 figs. Sanitary precautions to prevent decay; building of piles; and protection against fire.

M

MAGNESIUM ALLOYS

Electron Metal. The Magnesium Alloy "Electron," S. Beckinsale. Metal Industry (N. Y.), vol. 19, no. 11, Nov. 1921, p. 433. Gives chemical analysis of three specimens; hardness and compression tests; microscopic examination; machining properties.

MACHINE SHOPS

British. Famous British Works. Eng. Production, vol. 3, no. 59, Nov. 17, 1921, pp. 458–460, 7 figs. Works of Ruston & Hornsby, Ltd., Lincoln, known as Sheaf Iron Works, Wood Works, Motor Works, Boiler Works, and Steam Navy Works.

Design. The Design and Construction of Engineering Workshops—XXIV, Ernest G. Beck. Mech. World, vol. 70, no. 1817, Oct. 28, 1921, pp. 342–343, 6 figs. Discusses orientation of roofs; glare, glazing, screening, ventilation, etc. (To be continued).

MACHINE TOOLS

Automatic. Automatic Machine Tools in Relation to Production Problems, Henry Baker. Machinery (Lond.), vol. 19, no. 477, Nov. 17, 1921, pp. 181–185. Application of mathematical methods to tool setting; idle time; stoppages; economy of extra tools or extra machines.

Cooling-Water Pumps for. Cooling-Water Pumps for Machine Tools (Kühlwasserpumpen für Werkzeugmaschinen), Alfred Schacht. Fördertechnik u. Frachtverkehr, vol. 14, no. 21, Oct. 14, 1921, pp. 258–259, 2 figs. Describes motor-driven Elmo machine-tool cooling pumps patented by the Siemens-Schuckert Works, for which both direct and alternating current can be used.

Improving Details. Tool Details that Improve the Finish of Work in a Machine Shop. Eng. & Indus. Management, vol. 6, no. 21, Nov. 24, 1921, pp. 586–589, 12 figs. Gives practical advice on raising standard of quality of work, and details for improving machine tools, together with explanatory diagrams.

Operation Control. Some Notes on the Operating Control of Machine Tools, N. F. Stockbridge. British Machine Tool Eng., vol. 1, no. 12, Nov.-Dec. 1921, pp. 406–412, 11 figs. Discusses the various adjustments of the radial drilling machine up to 4 ft. 6 in. radius.

MALLEABLE CASTINGS

Annealing. Annealing Malleable Cast Iron (Le recuit de la fonte malléable), Christian Kluytmans. La Fonderie Moderne, no. 8, August 1921, pp. 209–218, 2 figs. Shows that on annealing depends the success or failure of malleability, if composition is correct.

MARINE STEAM TURBINES

Drive. Stal's New Marine Turbine Drive (Stal:s nya turbomekaniska fartygsmaskineri), O. A. Wiberg. Teknisk Tidskrift, vol. 51, no. 9, Sept. 28, 1921, pp. 89–95, 10 figs. Describes turbine and propeller arrangements and gives tables showing saving effected.

METAL SPRAYING

Schoop Process. Metal Spraying by the Schoop Process, Sidney Mornington. Compressed Air Mag., vol. 26, no. 11, Nov. 1921, pp. 10293–10295, 5 figs. Promises to be of great industrial value for applying zinc or lead to bridges, pontoons, railway cars, and other equipment exposed to action of the elements or exhaust gases.

METALS

Elasticity. Testing Machine Indicating the Elastic limit and the Modulus of Elasticity of Metals (Machines d'essais, donnant la limite élastique et le module d'élasticité des métaux), R. Guillery. Comptes Rendu des Séances de l'Académie des Sciences, vol. 173, no. 20, Nov 14, 1921, pp. 907–909, 1 fig. Describes new method and apparatus.

Fatigue. An Investigation of the Fatigue of Metals, H. F. Moore and J. B. Kommers. University of Illinois Bul, vol. 19, no 8, Oct 24, 1921, 185 pp., 46 figs. Report of investigation conducted by Engineering Experiment Station in coöperation with Nat. Research Council, Engineering Foundation, and Gen. Elec. Co. Concludes that phenomenon known as fatigue under repeated stress might better be called progressive failure of metals. Most probable explanation seems to be that such failure is progressive spread of microscopic fractures. Bibliography. See also Eng. & Contracting, vol. 56, no. 26, Dec. 28, 1921, pp. 593–596, 5 figs.

Hardening. On the Theory of the Hardening of Metals, Kotaro Honda. Chem. & Met. Eng., vol. 25, no. 22, Nov. 30, 1921, pp. 1001–1003. Thinks that hardness in metals is due in part to forces between atoms and in part to an interlocked, strained crystalline structure.

Light and Extra Light. Light and Extra Light Metals (Les Métaux blancs légers et ultra légers), R. de Fleury. La Fonderie Moderne, no. 10, Oct. 1921, pp. 294–298. Discusses alloys with aluminum or magnesium base, compares light and heavy metals casting of aluminum; treatment of light metals; alloys of aluminum.

MILLING

Problems. Some Miller Problems—How They Were Solved, H. A. Wilson. Can. Machy., vol. 26, no. 20, Nov. 17, 1921, pp. 33–34, 4 figs. Milling steel parts to within limits of .002 in. at the rate of 600 per hour; milling four tables at one time; value of gang milling.

MILLING CUTTERS

Action of. On the Art of Milling, John Airey. Mech. Eng., vol. 43, no. 12, Dec. 1921, pp. 783–789 and 798, 17 figs. Account of investigation undertaken at University of Michigan for purpose of finding rational basis for action of milling cutter. It is shown that metal is removed more efficiently with thick than with thin chips; thus, under usual conditions, cutter with fewest teeth gives greatest efficiency. Formulas for determining number of teeth for known diameter of cutter and for determining depth are included.

MOLDING METHODS

Jarring Machines. Germans Jar Molds Mechanically, U. Lohse. Foundry, vol. 49, no. 23, Dec. 1, 1921, pp. 934–938, 8 figs. Compares different methods of packing sand in molds; mechanical jarring machines, both with and without shock absorbers are described in detail. (Abstract). Stahl und Eisen, Sept. 1, 1921.

MOTOR-TRUCK TRANSPORTATION

Costs. A Formula Covering Costs of Heavy Motor Trucking, Charles Hine. Ry. Age, vol. 71, no. 22, Nov. 26, 1921, pp. 1045–1046, 1 fig. Shows superiority of time basis over ton-miles or truck-miles for computing expenses.

MOTOR TRUCKS

British Types. Engineering Features of British Truck Models, M. W. Bourdon. Automotive Industries, vol. 45, no. 20, Nov. 17, 1921, pp. 958–963, 14 figs. Describes new design features in the 6-ton Maudslay, 4-ton Dennis, and other trucks.

Electric vs. Gasoline. Electric Vehicle Operation Cheaper than Gasoline Truck, Walter R. Metz. Elec. World, vol. 78, no. 24, Dec. 10, 1921, pp. 1173–1174, 2 figs. Operating costs of electric trucks in government service in Washington, D. C., compared with cost of gasoline trucks under similar conditions; electric trucks superior for city requirements.

Vibration, Reduction of. Reducing Destructive Vibration in Equipment. Elec. Traction, vol. 17, no. 11, Nov. 1921, pp. 805–809, 9 figs. Discusses crystallization and fatigue, experience in motor-truck field, use of ball and roller bearings, cushioning shocks, types of cushion wheels, etc..

N

NICKEL STEEL

Invar. Properties and Uses of Invar Metal (Les propriétes et les applications de l'invar et de l'invar), Ch.-Ed. Guillaume. Bulletin de la Société Industrielle de Mulhouse, vol. 87, no. 6, June-July-August 1921, pp. 291–318, 13 figs. Discusses nickel-steel alloys and their magnetic properties; expansion of invar, which name is derived from "invariable;" also "elinvar" metal, having an invariable modulus of elasticity. Used for watch compensation, etc.

NOZZLES

Measurement of Flow. Use of Nozzles for Measuring Flow, W. Trinks. Power Plant Eng., vol. 25, no. 21, Nov. 1, 1921, pp. 1044–1045, 4 figs. Methods of reducing fluctuations in flow to and from air compressors and steam engines.

O

OIL ENGINES

Function of. Function of the Heavy Oil Engine in Connection with the General Supply of Electricity, Geoffrey Porter. Petroleum World, vol. 13, no. 254, Nov. 1921, pp. 466–470. Discusses fuels available, compares steam and oil engine stations; local versus bulk electricity supply; etc. (Abstract). Paper read before Diesel Engine Users Assn.

Marine. Worthington Airless-Injection Oil-Engine. Motorship, vol. 6, no. 11, Nov. 1921, pp. 872–875, 12 figs. Details of a new marine motor for small commercial vessels developed at Blake Works, East Cambridge; successful tests run on regular steam-boiler fuel oil with low-consumption results.

Two-Cycle. A Two-Cycle Oil Engine. Engineer, vol. 132, no. 3438, Nov. 18, 1921, p. 544, 3 figs. Describes two-stroke hot-bulb type constructed by Marshall, Sons & Co., Ltd., Gainsborough.

OIL FUEL.

Textile Mills. Oil Fuel for Textile Works, J. Veen Stevens. Eng. & Indus. Management, vol. 6, no. 21, Nov. 24, 1921, pp. 597–598. Tests for standardizing quality. Paper read before British Assn. of Mgrs. of Textile Works.

OPEN-HEARTH FURNACES

Coke-Oven Gas in. Using Coke Oven Gas in Martin Furnaces (Utilisation du gaz de fours a coke pour le chauffage des fours Martin), Jean Dupuis. Révue de L'Industrie Minérale, no. 20, Oct. 15, 1921, pp. 627–633. Discusses combustion using rich gas, rich and poor gas without mixing, and rich and poor mixed, and experiments carried out.

Ports, Improving. Improving Ports of Open Hearths, John W. Kagarise. Iron Trade Rev., vol. 69, no. 22, Dec. 1, 1921, pp. 1417–1421 and 1426, 6 figs. Various types of water-cooled ports are described. Using by-product coke-oven gas introduces difficulty. Paper read before Am. Iron & Steel Inst.

Improvements in Open-Hearth Port Construction, John W. Kagarise. Iron Age, vol. 108, no. 21, Nov. 24, 1921, pp. 1324 and 1326–1329. Early types; water-cooled ports; the McKune system and the Venturi and Egler furnaces with some results. Paper read before Am. Iron & Steel Inst.

OXY-ACETYLENE WELDING

Mild Steel. A Survey of Oxyacetylene Welding, Lorn Campbell, Jr. Jl. Soc. Automotive Engrs., vol. 9, no. 5, Nov. 1921, pp. 320–321 and (discussion) 321–322. Discusses the subject as a factor of efficiency in manufacturing; gives reasons why rivets should be replaced by welds; outlines mild steel welding and describes apparatus.

P

PAINTS

Drying. Artificial versus Natural Means of Drying Paint and Varnish, R. E. Lippert. Jl. Soc. Automotive Engrs., vol. 9, no. 5, Nov. 1921, pp. 335–340 and (discussion) 340–343, 13 figs. Describes process for drying coats of paint and varnish by adding heat and moisture simultaneously to air surrounding siccative coatings through employment of mechanical devices; also describes several humidifying devices.

PATTERNMAKING

Layout and Equipment. Pattern-making Lay-out and Equipment, James Edgar. Eng. & Indus. Management, vol. 6, no. 22, Dec. 1, 1921, pp. 624–625. Practical advice covering essential features of organization. Notes on type of vice, position of machines, and sawing machine.

PATTERNS

Storage. The Organization of a Pattern Stores, H. Varley. Eng. & Indus. Management, vol. 6, no. 19, Nov. 1921, pp. 522–525, 10 figs. Describes storage method and manner of running stores which is claimed to be common-sense application of systematic routine reduced to its simplest terms.

PETROLEUM

Refining. Modern Oil Refineries (Moderne oliefabricksinstallatie), F. C. Huygen. Ingenieur, vol. 36, no. 43, Oct. 22, 1921, pp. 842–847, 12 figs. Describes equipment and operations of plant of Atrecht Machine Works, including hydraulic, chemical and electrolytic methods; hydrogenations; etc.

PIGMENTS

Paint and Rubber. A Photomicrographic Method for the Determination of Particle Size of Paint and Rubber Pigments, Henry Green. Jl. Franklin Inst., vol. 192, no. 5, Nov. 1921, pp. 637–666, 13 figs. Describes method of determining "diameter" of paint and rubber pigments, by first taking a photomicrograph of sample, at carefully ascertained magnification, and again enlarging by means of a stereopticon and then measuring particles on projecting screen.

PIPE, CAST-IRON

Centrifugal Casting. Manufacture of Cast Iron Pipe by Centrifugal Methods, F. W. Hudson. Contract Rec., vol. 35, no. 48, Nov. 30, 1921, pp. 1038–1039, 2 figs. Describes the DeLavaud process and machinery. Comparison of centrifugal product with sand-cast pipe.

PIPE, STEEL

Protective Covering. Protective Covering for Steel Pipe, L. M. Klauber. Gas Age-Rec., vol. 48, nos 14 and 15, Oct. 22 and 29, 1921, pp. 478–484 and 514–516, 21 figs. Oct. 22: Describes method of covering pipe for protection in corrosive soils used by San Diego Consolidated Gas & Elec. Co. The clean pipe is dipped into hot asphalt, wrapped with chemically and electrically resistant asbestos felt redipped in asphalt and wrapped spirally with burlap. Oct. 29: Tests with some coverings, materials for wrapping, life of pipe, etc.

PISTONS

Machining Bosses. Machining Piston Bosses. Eng. Production, vol. 3, no. 58, Nov. 10, 1921, p. 450, 3 figs. Describes method for intensive production.

PLANERS

Helical-Geared Drive. The New Gray Planer. Machy. (N. Y.), vol. 28, no. 4, Dec. 1921, pp. 285–289, 6 figs. Machine with helical-geared table drive, designed to render maximum service under modern requirements.

POWER

Costs. How to Follow Up Power Costs—II, N. A. Craigue. Indus. Management, vol. 62, no 6, Dec. 1921, pp. 354–356, 1 fig. Discusses various methods of distribution, such as by estimated percentages, by metered amounts, and unit cost or cost constant method.

Hydraulic, Storage of. Mechanical Storage of Power in Italy, G. Müller. Power, vol. 54, no. 21, Nov. 22, 1921, pp. 804–805, 2 figs. Discusses storage of hydraulic energy by using surplus power during periods of high water or low demand, to pump water from tailrace back to higher level for use during peaks or periods of drought. Notes on the Viverone plant,

Funghera mechanical storage plant and a large one under construction.

POWER GENERATION

By-Product Recovery. The Generation of Power with Recovery of By-Products (Krafterzeugung mit Gewinnung von Wertstoffen), H. Kreyssig. Gas- u. Wasserfach, vol. 64, no. 35, Sept. 3, 1921, pp. 557–560. Study of methods for the complete utilization of coal in connection with generation of electrical energy. Merits of gas and oil turbines.

Fuel Economy. Fuel Economy by the Adoption of Scientific Management in Steam Power Generation and Utilisation, David Brownlie. Eng. & Indus. Management, vol. 6, nos. 17, 18, 19, 20, 21 and 22, Oct. 27, Nov. 3, 10, 17, 24 and Dec. 1, 1921, pp. 473–475, 516–520, 549–552, 559–562, 593–594 and 626–630 and 637, 31 figs. Oct. 27: Boiler feedwater meters. Nov. 3: Steam meters. Nov. 10: Steam meters and feedwater regulators. Nov. 17: Feedwater regulators and coal weighing. Nov. 24: Coal weighing. Dec. 1: Economizers.

POWER PLANTS

Code on Definitions and Values. Code on Definitions and Values. Mech. Eng., vol. 43, no. 12, Dec. 1921, pp. 805–810 and 821. Preliminary draft of fourth in series of 19 codes in preparation by A.S.M.E. committee on power tests codes.

Design. Developments in Power Station Design. Engineer, vol. 132, nos. 3447, 3438, 3439 and 3440, Nov. 11, 18, 25 and Dec. 2, 1921, pp. 502–504, 5 figs; 530–532, 8 figs., 558–559, 4 figs., and 600–601, 7 figs. Nov. 11: Lopulco pulverized-coal feeders and equipment. Nov. 18: Self-cleaning multiple-retort stokers, ash-removal equipments. Nov. 25: Coal-storage system of Ed. Bennis & Co., Ltd., and ash removal from boiler houses. Dec. 2: Pneumatic coal-handling plant at Bankside electric generating station, London.

Oiling Systems. Central Oiling Systems for Power Plants. Power House, vol. 14, no. 21, Nov. 5, 1921, pp. 32–33. The treatment of oil for continuous use; correct lubrication; impurities, precipitation; filtration, entrained water; action of heat; filtering materials, separation of water.

Operation. Refinements of Practice in Modern Power Plants, I. L. Kentish-Rankin. Power Plant Eng., vol. 25, no. 24, Dec. 15, 1921, pp. 1190–1192. Turning steam into cold pipe lines; handling hot water; precautions for instrument piping; flue dusts and their chemical actions; moisture in superheated steam lines.

Records and Accounting. Power Plant Records and Accounting, Einar Winholt. Power Plant Eng., vol. 25, no. 24, Dec. 15, 1921, pp. 1193–1196, 6 figs. Discusses total cost of operating power plant, distribution of cost, and gives forms.

Waste in. Waste in Industrial Power Plants, David Moffat Myers. Management Eng., vol. 1, no. 6, Dec. 1921, pp. 370–371. Notes on how to determine efficiency of operation.

POWER TRANSMISSION

Waves. Wave Transmission of Power. Steamship, vol. 33, no. 389, Nov. 1921, pp. 142–154, 13 figs. Theoretical discussion by G. Constantinesco. Discusses power transmission by waves through liquids and its application to rock drills, riveters, etc. made by W. H. Dorman & Co., Shafford, Eng.

PRODUCER GAS

Coke-Oven Heating. Producer Gas for Coke Oven Heating. Colliery Guardian, vol. 122, no. 3177, Nov. 18, 1921, pp. 1403–1404, 5 figs. Discusses trend of progress in coke industry. Notes on Koppers regenerative coke oven and regenerative gas oven.

PULVERIZED COAL

Assay Muffles. Firing Assay Muffles with Pulverized Coal, E. H. Hamilton. Min. & Metallurgy, no. 180, Dec. 1921, p. 24, 2 figs. Describes satisfactory burning of pulverized coal in assay furnaces of U. S. Smelting Refining & Mining Co., Midvale, Utah.

Boiler Equipment. Burning Anthracite Mine Waste Efficiently, O. M. Rau. Power, vol. 54, no. 22, Nov. 29, 1921, pp. 828–832, 8 figs. Results of tests obtained by burning pulverized anthracite coal in Philadelphia Rapid Transit Co.'s power plant. Pulverizing equipment installed for ten boilers.

Costs, Arizona. Experience with Powdered Coal in Arizona, J. B. Johnson. Elec. World, vol. 78, no. 23, Dec. 3, 1921, pp. 1121–1123, 1 fig. Costs less than fuel oil per B.t.u. in this case; detailed costs of pulverizing given.

Firing with. Firing With Powdered Coal (Het stoken met kolenpoeder), I. Franco. Ingenieur, vol. 36, no. 45, Nov. 5, 1921, pp. 875–892 and (discussion) 892–894, 50 figs. Notes on consumption of anthracite and other fuels, pulverized-coal installations, pulverizers, etc. Discusses advantages, application in locomotives, etc.

Power-Plant Equipment. Burning Pulverized Anthracite Mine Waste, O. M. Rau. Elec. Ry. Jl., vol. 58, no. 22, Nov. 26, 1921, pp. 915–919, 8 figs. Results of tests obtained by burning pulverized anthracite coal in Philadelphia Rapid Transit Company's power plant; pulverizing equipment installed for ten boilers.

PUMPS

Air-Lift. Air-Lift in Theory and Practice, A. W. Allen. Min. & Sci. Press, vol. 123, no. 21, Nov. 19, 1921, pp. 711–712. Discusses essentials for air lifting, design of rising main, elevating solids by air lift, elasticity, and advantages and disadvantages of air lift.

Rotary. Inbye Pumping, with Special Reference to the Feuerheerd Pump, S. H. Cashmore. Colliery Guardian, vol. 122, no. 3172, Oct. 14, 1921, pp. 1073–1074, 5 figs. Comparison of various types of pumps, describes the Feuerheerd pump which is claimed to have a great future. Read before South Staffordshire and Warwickshire Inst. Min. Engrs.

PUMPS, CENTRIFUGAL

Impellers. Open vs. Closed Impellers in the Brockton Sewage Pumping Plant, H. S. Crocker. Eng. News-Rec., vol. 87, no. 21, Nov. 24, 1921, pp. 851–856. Experience at Brockton, Mass., shows that open type impeller properly designed will give greater output and higher efficiency than enclosed one for small high-speed pumps.

PYROMETERS

Féry. The Measurement of Temperature—XV, P. Field Foster. Mech. World, vol. 70, no. 1819, Nov. 11, 1921, pp. 382–383, 8 figs. Describes the Féry radiation pyrometer.

High-Temperature Measurement. The Measurement of High Temperatures with the "Ardometer" and the Holborn-Kurlbaum Pyrometer (Die Messung hoher Temperaturen mit Ardometer und Holborn-Kurlbaum-Pyrometer), Georg Keinath. Siemens-Zeit., vol. 1, nos. 9 and 10, Sept. and Oct. 1921, pp. 331–340, and 358–364, 20 figs. Describes two instruments, one measuring by contrast between a hot lamp filament and the hot body; and other concentrating heat from hot body upon a small thermocouple the e.m.f. of which is measured on millivoltmeter calibrated in degrees. They give desired reading within a few seconds with accuracy of ±10 deg. cent.

Recording and Non-Recording. Pyrometer Solves Temperature Problems, John P. Goheen. Foundry, vol. 49, no. 23, Dec. 1, 1921, pp. 938–939. Discusses non-recording and recording pyrometers and their application, temperature control of furnaces, etc. Paper to be read before Am. Inst. Min. & Met. Engrs.

R

RADIOMETALLOGRAPHY

Industrial Applications. Industrial Applications of Radiometallography (La Radiometallographie, sa pratique et ses applications industrielles). Le Génie Civil, vol. 79, no. 16, Oct. 15, 1921, pp. 321–323, 6 figs. Describes equipment of X-ray testing laboratory.

RAILWAY ELECTRIFICATION

Boston-Washington. Plan for Electrifying Sections of Eleven Railroads. Ry. Mech. Engr., vol. 95, no. 12, Dec. 1921, pp. 739–743, 9 figs. Superpower report provides for consolidation of power supply in region between Boston and Washington.

Brazil. The Paulista Railway Electrification, S. B. Cooper. Ry. & Locomotive Eng., vol. 34, no. 11, Nov. 1921, pp. 304–306, 3 figs. Discusses new line of Companhia Paulista de Estradas de Ferro, between Jundiahy and Campinas, Brazil. Baldwin-Westinghouse electric locomotives, type 2–4–0+0–4–2 for passenger service, and 0–6–0+0–6–0 for freight.

Chile. Chile Starts on Extensive Electrification Program. Elec. Ry. Jl., vol. 58, no. 23, Dec. 3, 1921, pp. 991–993, 5 figs. First zone of State Railways, comprising 144 miles, which includes Valparaiso-Santiago line, to be completely electrified at 3,000 volts d.c.

France. Electrification of French Railways and American Experience (L'Electrification des chemins de fer Français et l'experience Americaine), A.-R. Garnier. La Technique Moderne, vol. 13, nos. 4, 5, 7 and 8, Apr., May, July and Aug. 1921, pp. 167–173, 209–217, 305–315 and 346–356, 19 figs. Apr.: Gives tabulation of efficiency of single- and three-phase systems; cost of installation; American and Canadian lines; etc. May: Reviews French, Swiss, Italian, German and American electrification; power, substations and their equipment, motor generators, locomotives, etc. July: High- and low-tension apparatus, direct control for fast trains, auxiliaries, transmission systems, etc. Aug.: Practical results obtained in Europe and America; tables of power consumption etc. of various lines; further electrification projects by French roads. (Concluded.)

RAILWAY OPERATION

Automatic Train Control. An Automatic Mechanical Train Controller. Engineer, vol. 132, no. 3437, Nov. 11, 1921, pp. 520–521, 4 figs. Details of device for automatically giving warning in cab of locomotive of position of signals on line, and for simultaneously applying brakes.

Automatic Train Control, North Eastern Railway. Ry. Gaz., vol. 35, no. 21, Nov. 18, 1921, pp. 765–767, 5 figs. Describes system which has been in use for many years, and is applicable to engines and stock fitted with Westinghouse, Westinghouse and vacuum combined, or vacuum brakes alone.

The "Daniels" Automatic Train-Stop. Ry. Gaz., vol. 35, no. 19, Nov. 4, 1921, pp. 683–685, 5 figs. New, exclusively mechanical, train stop, designed to give warning at distant signal and to cause a partial application of brakes, and at stop signals, should they be passed at "danger," to cause a further positive brake application, and to shut off steam. Apparatus provides for a distinct audible indication as a "clear" signal of either type is passed.

Lackawanna. Lackawanna Success the Result of Supervision, Charles W. Foss and James G. Lyne. Ry. Age, vol. 71, nos. 22 and 23, Nov. 26 and Dec. 3, 1921, pp. 1027–1032 and 1097–1102, 24 figs. Nov. 26: Notes on service, elimination of grades and curvature, locomotives, freight and passenger cars, and handling of coal. Dec. 3: Details of handling of coal and manifest freight.

Light Railways. On the Question of Operation of Light Railways, Working Rules and Regulations, F. Level. Bul. Int. Ry. Assn., vol. 3, no. 10, Oct. 1921, pp. 1471–1482. Summary of replies from 106 administrations to questions regarding classes of tickets, issuing, collecting, checking, etc.

Safety Appliances. On the Question of Safety Appliances on Light Railways, A. Bonnevie. Bul. Int. Ry. Assn., vol. 3, no. 10, Oct. 1921, pp. 1539–1588. Gives tabulation of lines in various countries and the length, gage, gradients, curve radii, maximum load, brakes, couplings, speeds, number of trains, track, signals, etc.

Standardization. Railway Standardization and Operation (Normung und Wartung), H. Mattersdorff. Verkehrstechnik, vol. 38, no. 24, Aug. 25, 1921, pp. 363–369, 8 figs. Notes on present status of standardization and its limitations; relations between standardization and operation; and advantages to be gained by a standardized operation.

RAILWAY REPAIR SHOPS

Modern. Modern Railway Shops and Repair Shops (Neuzeitliche Eisenbahn-Betriebs- und Ausbesserungswerke), M. Osthoff. Zeit. des Vereines deutscher Ingenieure, vol. 65, nos. 44 and 45, Oct. 29 and Nov. 5, 1921, pp. 1131–1134 and 1187–1191, 13 figs. Describes following plans: (1) Railway shop for dismantling of locomotives, equipped with a traveling wide-gage grab slewing crane, and connected with which is an efficient repair shop and a cattle-car cleaning house; (2) railway repair shop without traveling platform, in which locomotives, tenders and boilers can be mounted in either vertical or horizontal position.

RAILWAY SHOPS

Operations and Apparatus. Railroad Shop Operations and Apparatus, Frank A. Stanley. Am. Mach., vol. 55, no. 23, Dec. 8, 1921, pp. 922–923, 9 figs. Describes "home-made" acetylene gas generator; cutting continuous threads on staybolts; systematic arrangement of tools.

RAILWAY SIGNALING

Liverpool Overhead Railway. The Re-Signalling at the Liverpool Overhead Railway. Engineer, vol. 132, no. 3436, Nov. 4, 1921, pp. 488–489, 3 figs. Signaling is arranged on a 2-min. service, but actually is based on interval between trains of 100 sec. Notes on overlaps; light signals; color-light signals; track transformers, relays, etc.; train stops; and emergency cross-over roads.

Track Circuits, A.C. Shunting Characteristics of the Relay in an A-C. Track Circuit Employed in Railroad Signaling, C. F. Estwick. Jl. Am. Inst. Elec. Engrs., vol. 40, no. 12, Dec. 1921, pp. 919–925, 5 figs. Study of various characteristics of track circuit particularly in connection with shunting action of relay.

RAILWAY TIES

Wooden. Wooden Ties (Holzschwellenbeschaffung), E. Stephan. Verkehrstechnik, vol. 38, special no., Sept. 1921, pp. 408–410. Discusses relative economy of treated and untreated ties.

RAILWAY TRACK

Crossings. Railroad Crossings and Crossing Signs, R. S. Messenger. Elec. Ry. Jl., vol. 58, no. 17, Oct. 22, 1921, pp. 744–745. Suggests standardization to reduce accidents. (Abstract). Paper read before National Safety Council.

RAILWAY YARDS

Shunting Cars. Suggestions for the Most Economical Shunting of Railway Cars on Private Sidings (Welche Mittel gibt es, um das Rangieren der Eisenbahnwaggons auf den Privatanschulssgleisen auf möglichst billige Weise zu erledigen-), Ernst Varenkamp. Fördertechnik u. Frachtverkehr, vol. 14, no. 22, Oct. 28, 1921, pp. 274–277. Rope shunting installations and shunting winches.

REFRACTORIES

Research. Report of the Refractories Materials Committee. Gas World, vol. 75, no. 1943, Oct. 15, 1921, pp. 322–324 and (discussion) 324–325, 1 fig. Notes on jointing materials, including softening-point of mixtures of silica brick and clay firebrick, and mixtures of fireclay with fireclay grog; research.

REFRIGERATION

Total-Heat Diagram. Solving Refrigerating Problems by the Total Heat Diagram. Power, vol. 54, no. 22, Nov. 29, 1921, pp. 839–841, 3 figs. Describes use of Mollier diagram or total heat chart based on Goodenough's table of the properties of ammonia.

REFUSE DISPOSAL

Smelting. The Utilization of Refuse Through Smelting (Die Müllverwertung durch Schmelzung), Hermann Koschmieder. Gesundheits-Ingenieur, vol. 44, no. 35, Aug. 27, 1921, pp. 429–432. Refers to unsuccessful results of tests with smelting of refuse in Berlin according to Wegner system, and describes new process which, it is claimed, gives promise of better results.

ROLLING MILLS

Electrically Driven. Motor Equipment for Main Drive of Rolling Mills. Electrician, vol. 87, no. 2270, Nov. 18, 1921, pp. 647–653. List of particulars of electrically-driven rolling mills.

The Future of the Electrically Driven Rolling Mill, L. Rothera. Electrician, vol. 87, no. 2270, Nov. 18, 1921, pp. 632–633. Discusses cost of production and electric drive, influence of power

factor, and the chance for the gas engine with available gas supplied from blast furnaces and coke ovens.

Flywheel Engines. Flywheel Rolling-Mill Engines (Ueber Schwungrad-Walzenzugmaschinen), K. Möbus. Stahl u. Eisen, vol. 41, no. 46, Nov. 17, 1921, pp. 1649–1653, 7 figs. Discusses different types of single-cylinder steam engines in capacity of rolling-mill engines, particularly in connection with central condensation plants; and describes and recommends special type of machine, consisting of a combination of steam and gas engine.

Motors, Size of. Factors which Influence the Size of Rolling Mill Drives, L. Rothera. English Elec. Jl., vol. 1, no. 7, July-October 1921, pp. 291–297, 8 figs. Discusses power demand for rolling various sections, output required and methods of rolling, as factors in determining size of motor.

ROPE

Manila. Results of Some Tests of Manila Rope, Ambrose H. Stang and Lory R. Strickenberg. U. S. Bur. of Standards Technologic Papers, no. 198, Sept. 15, 1921, 11 pp. Summary of results of tensile tests of 368 specimens of rope, all of which were 3-strand, regular lay manila rope having diameters from 1/2 in. to 4 1/2 in. are given in tables and graphically. Gives formula for determining average breaking load as function of diameter of rope. Ropes showed continually varying modulus of elasticity and no well-defined proportional limit.

RUBBER

Aging. The Aging of Rubber, Andrew H. King. Chem. & Met. Eng., vol. 25, no. 23, Dec. 7, 1921, pp. 1039–1042. Aging tests and aging hypothesis; acceleration of oxidation; depolymerization; comparison between still and active aging.

Microsectioning. Recent Development in the Art of Rubber Microsectioning, Henry Green. Jl. Indus. & Eng. Chem., vol. 13, no. 12, Dec. 1921, pp. 1130–1132, 11 figs. Describes chemical method as an alternative to freezing method. Paper read before Am. Chem. Soc.

Vulcanization. The Relation between Coefficient of Vulcanization and Mechanical Properties of Vulcanized Rubber, O. de Vries. Jl. Indus. & Eng. Chem., vol. 13, no. 12, Dec. 1921, pp. 1133–1134. Results of investigations showing that the natural accelerator or accelerators in rubber cause an increase in coefficient of vulcanization for fixed mechanical properties which amounts to about 0.5 for all types of quick-curing rubber, independent of their composition.

S

SAFETY

Inspection. Safety Inspectors and Inspections, John A. Dickinson. Am. Mach., vol. 55, no. 22, Dec. 1, 1921, pp. 887–869. Different types of inspection. Importance of standardizing safeguards. Advantages of helping inspectors.

SCALES

Inspection and Maintenance. Inspection and Maintenance of Weighing Scales, Herbert T. Wade. Management Eng., vol. 1, no. 5, Nov. 1921, pp. 289–294, 10 figs. Describes scale-inspection department of the Scovill Mfg. Co., Waterbury, Conn. Scale service organizations.

Locomotive. Locomotive Weighing Plant of Large Capacity, Carl C. Bailey. Ry. Mech. Engr., vol. 95, no. 12, Dec. 1921, pp. 749–750, 3 figs. Heavy scale is housed in special building with equipment for determining all wheel loads at one time.

SCIENTIFIC MANAGEMENT

See INDUSTRIAL MANAGEMENT; TAYLOR SYSTEM.

SEAPLANES

Deck-Landing Amphibian. The Supermarine "Seal," Mark II. Flight, vol. 13, no. 44, Nov. 3, 1921, pp. 713–715, 5 figs. Has cruising radius of five hours; total military load, including fuel is 1790 lb. Describes details of construction as far as public, of this deck-landing amphibian fleet-spotter.

German. Some New German Seaplanes, Erik Hildsheim. Aviation, vol. 11, no. 21, Nov. 21, 1921, pp. 594–596, 11 figs. Describes L.F.G. commercial seaplanes, new Dornier flying boats, and gives table of data.

Gliders. Hydroplanes (Gliders) With Multiple Redans and Air Screws (Sugli idroplani (glisseurs) a redans multipli ed elica aerea), Dino Giuliani. Revista Marittima, vol. 54, no. 10, Oct 1921, pp. 169–183, 5 figs. Describes existing types of flying boats, hydroplanes, etc. and gives formulas for calculations.

SEMI-DIESEL ENGINES

Beardmore. Construction of Internal-Combustion Engines. Shipbldg. & Shipg. Rec., vol. 18, no. 22, Dec. 1, 1921, pp. 703–708, 9 figs. Describes the Beardmore semi Diesel oil engines.

SHAPERS

Use in Production Work. Production Shaping. Machy. (N. Y.), vol. 28, no. 4, Dec. 1921, pp. 272–276, 9 figs. Use of shapers in production work in machine-tool building plants.

SILICA BRICK

Manufacture and Use. Manufacture and Use of Silica Brick, Jefferson Middleton. Cem., Mill & Quarry, vol. 19, no. 9, Nov. 5, 1921, pp. 25–27. How material is ground and washed. Burning brick in circular down-draft kilns. Used for purposes where temperatures are high. (Abstract). Mineral Resources of U. S.

STANDARDIZATION

Germany. Industrial Standardization in Germany. Automotive Industries, vol. 45, no. 23, Dec. 8, 1921, p. 1127. Discusses national standardization as developed in Germany under post-war conditions.

Industrial Standardization in Germany, P. G. Agnew. Jl. Am. Soc. Heating & Ventilating Engrs., vol. 27, no. 8, Nov. 1921, pp. 794–796. Describes advanced state of industrial standardization in Germany. 144 approved standards sheets have been issued and over 500 others have been developed Notes on organization and methods of work.

Industrial. Industrial Standardization. Jl. Soc. Automotive Engrs., vol. 9, no. 6, Dec. 1921, pp. 359–435, 66 figs. A number of articles on standardization, including standardization in Germany, S.A.E. standardization, automobile standardization in Great Britain, decreasing production costs through standardization, and reports of divisions to A.S.E. Standards Committee.

Inter-works. Standardisation and Assimilation, H. Varley. Eng. & Indus. Management, vol. 6, no. 20, Nov. 17, 1921, pp. 554–556. Writer advances plea for wider adoption of inter-works standardization and explains where and how it can be performed and applied.

STANDARDS

German N.D.I. Report. German Industry Committee on Standards (Normenausschuss der Deutschen Industrie). Betrieb, vol. 4, no. 1, Oct. 8, 1921, pp. 1–9, 8 figs. Proposals of the Board of Directors for blank hexagonal nuts, blank washers, low dimensions for drills and countersinks, diameters of core drills; sink-water traps with openings and with covers. Proposed standards for copper and brass.

German Industry Committee on Standards (Normenausschuss der Deutschen Industrie). Betrieb, vol. 4, no. 2, Oct. 22, 1921, pp. 17–24, 9 figs. Proposed standards for offset and straight-arm hand cranks; brass; vector designations; permissible stresses in building material (mild steel and wood); terminology for cast iron, malleable iron, steel castings.

Importance of. Executives Should Foster Use of Standards, Herbert Chase. Automotive Industries, vol. 45, no. 23, Dec. 8, 1921, pp. 1101–1107, 2 figs. Proper use of standard specifications, fittings and dimensions tends to eliminate waste, save time and cut expenses. Engineers know value of standards, but executives have, in general, failed to realize their importance and encourage their use.

STEAM-ELECTRIC PLANTS

Superpower System. Steam-Electric Central Stations Retained for the Superpower System, Arthur R. Wellwood. Power, vol. 54, no. 25, Dec. 20, 1921, pp. 969–972, 5 figs. Existing steam-electric stations retained represent 80 per cent of all such stations in Superpower Zone, and were chosen as result of detailed analysis and study based upon their 1919 performance. Operation of retained plants.

STEAM ENGINES

Exhaust. Simplification and Reduction of Operating Costs of Exhaust-Steam Engines by Simultaneous Utilization of Furnace Waste Heat (Vereinfachung und Betriebsverbilligung von Abdampfkraftanlagen durch gleichzeitige Ausnutzung von Ofenabwärme), Ernst Blau. Fördertechnik u. Frachtverkehr, vol. 14, no. 8, Apr. 15, 1921, pp. 88–90, 4 figs. Describes "Gefa" patented process for operation of exhaust-steam storage plants.

Heat Utilization. The Utilization of Heat in Steam Engines (Wärmeausnutzung bei Kraftmaschinen), K. Heilmann. Zeit. für Dampfkessel u. Maschinenbetrieb, vol. 44, no. 40, Oct. 7, 1921, pp. 315–319, 6 figs. Discusses relations between exhaust-steam utilization and power generation.

STEAM PIPES

Flow in. Machinery and Pipe Arrangement Calculations—XIII, C. C. Pounder. Mech. World, vol. 70, no. 1819, Nov. 11, 1921, pp. 386–388, 1 fig. Continues discussion of safety-valve springs and gives examples and calculations; also discusses weight flow of steam through pipes.

Steam Flow in Pipes, F. M. Van Deventer. Power Plant Eng., vol. 25, no. 22, Nov. 15, 1921, pp. 1096–1098, 1 fig. Steam flow chart for superheated steam and table of pipe sizes.

STEAM POWER PLANTS

Heat-Balance Systems. Heat Balance in Steam Power Plants. Mech. Eng., vol 43, no. 12, Dec. 1921, pp. 790–796 and 825, 8 figs. Particulars of systems employed in three large modern stations, namely, Delaware Station of Philadelphia Elec. Co., by E. L. Hopping; Hell Gate Station, by J. H. Lawrence and W. M. Keenan; and Colfax Station, by C. W. E. Clarke.

Sanitarium. Steam for Battle Creek Sanitarium. Power Plant Eng., vol. 25, no. 23, Dec. 1, 1921, pp. 1131–1138, 14 figs. Mechanical coal and ash handling, automatically controlled underfeed stokers, special water treatment and graphic record system.

STEAM TURBINES

Critical Speeds. Simplified Approximations of Critical Speeds, G. Arrowsmith. Engineering, vol 112, no. 2917, Nov. 25, 1921, pp. 717–720, 8 figs. Points out that critical speeds can in very many cases be obtained without resource to tedious graphical constructions of bending moment and deflection diagrams.

Efficiency Calculations. Turbine Efficiency Calculations, Paul F. Christopher. Power Plant Eng., vol. 25, no. 21, Nov. 1, 1921, pp. 1039–1042, 3 figs. Use of heat-enthropy diagram in calculation of efficiency; estimating power load to meet demands for exhaust steam.

Steam Consumption. A Simple Method of Finding Steam Consumption of Small Turbines. Power, vol. 54, no. 23, Dec. 6, 1921, pp. 895–896, 3 figs. Presents curves for determining water-rate factor for any turbine at any load.

STEEL

Alloy. See ALLOY STEELS.

Carburizing. Present Theories of Carburizing Steel H. B. Knowlton. Forging & Heat Treating, vol. 7, no. 11, Nov. 1921, pp. 543–548, 14 figs. Application of theories to commercial problems; effect of different temperatures on per cent and distribution of carbon in the case.

Chrome. See CHROME STEEL.

Composition and Properties. Principal Steels and Their Characteristics and Uses (Les principaux aciers de construction, leurs caracteristiques et leurs emplois), P. Dejean. La Houille Blanche, vol. 20, no. 55–56, July-August 1921, pp. 149–154, 3 figs. Gives tables of composition and properties. Discusses carbon steels, mild steels, cementation steels, corrosion resistant steels, etc., and their uses.

Ingots, Defects in. Defects in Ingots and Methods for Remedying Them (Les défauts des lingots et les methodes pour y remedier), Sigma. La Metallurgie, vol. 53, no. 47, Nov. 24, 1921, pp. 2185–2186. Summarizes results of investigations by L. Guillet, including piping, cracks, segregation, etc.

Low-Carbon, Strain Lines in. Strain Lines in Low Carbon Steel, A. Fry. Iron Age, vol. 108, no. 22, Dec. 1, 1921, pp. 1401–1402, 10 figs. New German etching method revealing effects on metal which has been stressed. Origin and character of lines. Translated from Stahl u. Eisen, Aug. 11, 1921.

Magnetic Analysis. Magnetic Analysis of Steel, R. L. Sanford. Am. Mach., vol. 55, no. 21, Nov. 24, 1921, pp. 836–839, 7 figs. Uses of electric current for inspection. Apparatus and method of operation; relation of magnetic to mechanical properties of steel. Advantages and difficulties.

Stainless. Stainless Steel and Its Engineering Applications. Mech. World, vol. 70, no. 1817, Oct. 28, 1921, pp. 346–348, 3 figs. Describes tests made with stainless-steel turbine blades at works of Th. Firth & Sons, Sheffield, showing that the blades remained absolutely unaffected. Also discusses manufacture of stainless steel and its properties.

STEEL CASTINGS

Welding. The Welding of Steel Castings (Das Schweissen von Stahlguss), L. Treuheit. Giesserei-Zeitung, vol. 18, nos. 29–30 and 31, Nov. 1 and 8, 1921, pp. 389–392 and 404–408, 19 figs. Discusses application of the different processes, with special consideration of electric arc and antogeneous welding.

STEEL, HIGH-SPEED

Heat Treatment. Proper Heat Treatment for High Speed Steel, J. L. Thorne. Can. Machy., vol. 26, no. 19, Nov. 10, 1921, pp. 36–37 and 53. Gives instances of improper heat treatment, object of high temperature furnace; quenching the tool; heating cutting edges.

Tool Steel. Action of Internal Stress on Tool Steel, C. Neil Greenwood. Forging & Heat Treating, vol. 7, no. 11, Nov. 1921, pp. 560–563. Discusses origins of internal stresses in pure metals and alloys, due to cold working and to suppression of phase changes by rapid cooling; volume changes taking place during heating and cooling. (Abstract). Paper read at joint meeting of Faraday Soc. with other institutions.

Tungsten Content. Measures Tungsten in Tool Steel, Arthur S. Townsend. Iron Trade Rev., vol. 69, no. 24, Dec. 15, 1921, pp. 1551–1553. New method determines content of this element in high-speed steel by specific gravity. Results show that accurate data can be obtained without chemical analysis. Tests are made in few minutes.

STEEL INDUSTRY

Research in. Research in the Steel Industry, John A. Mathews. Min. & Metallurgy, no. 180, Dec. 1921, pp. 11–13. Discusses ways in which research department of steel company may function in order to contribute to success.

STEEL WORKS

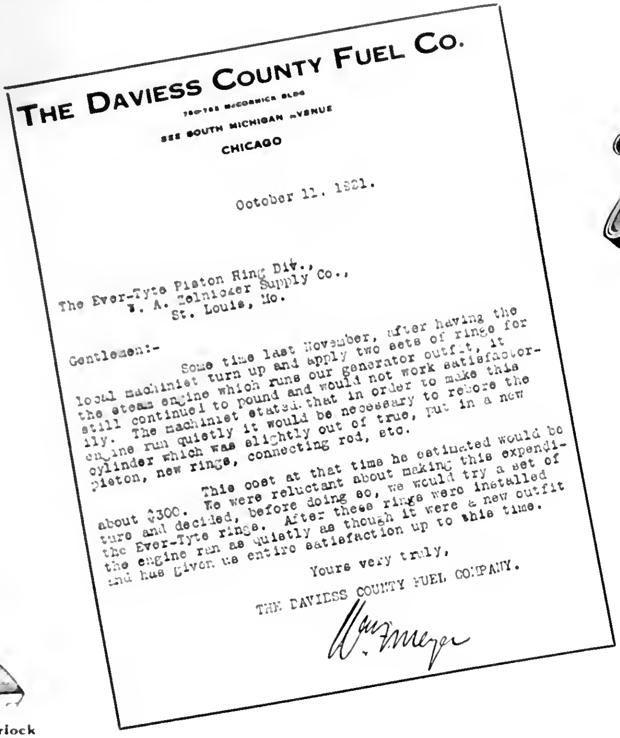
Brazil. Electric Iron and Steel Plant for Brazil, N. A. V. Paulson. Chem. & Met. Eng., vol. 25, no. 23, Dec. 7, 1921, pp. 1057–1061, 8 figs. This installation, first of its kind, includes two Swedish-type pig iron furnaces, two bessemer converters, a Ludlum steel furnace and two merchant mills, all driven by electric power and heated by electric energy.

English. Methods in a Modern Steel Works. Eng. Production, vol. 3, no. 62, Dec. 8, 1921, pp. 545–548, 9 figs. Describes plant and equipment of Thos. Firth & Sons, Ltd., Sheffield.

Heat Economy in. Improving the Economy of Heat in Metallurgical Works (Zur Verbesserung der Wärmewirtschaft der Hüttenwerke), Gustav Neumann. Stahl u. Eisen, vol. 41, no. 44, Nov. 3, 1921, pp. 1561–1569, 3 figs. Deals with storage of excess blast-furnace gas in air heaters and its useful possibilities; utilization of waste heat from furnaces; preheating of combustion air and gas; utilization of producer steam for generation of mechanical energy; improvement in design of air heaters from thermo-technical standpoint.

Lorraine, France. The Rombas Steel Works Near

It's what the USER says that counts



THE DAVIESS COUNTY FUEL CO.
750-752 McCORMICK BLDG
332 SOUTH MICHIGAN AVENUE
CHICAGO

October 11, 1921.

The Ever-Tyte Piston Ring Div.,
W. A. Zelnicker Supply Co.,
St. Louis, Mo.

Gentlemen:-

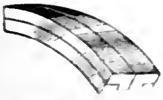
Some time last November, after having the local machinist turn up and apply two sets of rings for the steam engine which runs our generator outfit, it still continued to pound and would not work satisfactorily. The machinist stated that in order to make this engine run quietly it would be necessary to rebore the cylinder which was slightly out of true, put in a new piston, new rings, connecting rod, etc.

This cost at that time he estimated would be about $300. We were reluctant about making this expenditure and decided, before doing so, we would try a set of the Ever-Tyte rings. After these rings were installed the engine ran as quietly as though it were a new outfit and has given us entire satisfaction up to this time.

Yours very truly,

THE DAVIESS COUNTY FUEL COMPANY.

Wm. F. Meyer



The right-angled interlock is your safeguard

Mr. Meyer SAVED $215.00 on installation alone!

The ultimate saving resulting from higher efficiency, greater power output, lower fuel and oil consumption and reduced maintenance charges will be many times this amount.

Order On Trial

EVER-TYTE PISTON RING DIVISION **ST. LOUIS**

ENGINEERING INDEX (Continued)

Metz [Les aciéries de Rombas, pres Metz (Moselle)], Ch. Dantin. Le Génie Civil, vol. 79, no. 19, Nov. 5, 1921, pp. 385–393, 13 figs., partly on supp. plate. Describes works of Société Lorraine des Aciéries de Rombas, blast furnaces, Cowper apparatus, blowers, electric power station, rolling mills, etc.

STOKERS

Automatic. Use of Automatic Stoking in Industries (L'Emploi des foyers automatiques dans l'industrie), H. Drouot and F. Verdeaux La Technique Moderne, vol. 13, nos. 8 and 9, Aug. and Sept. 1921, pp. 337–343 and 376–383, 37 figs. Aug.: Discusses the various arrangements of grates and stokers, including those by Wackernie, Forney, Leach, Wilkinson, Godillot, Grieve, Babcock & Wilcox, Hotchkiss, Coxe, Ill. Stoker Co.; Green's ash conveyor. Sept. Discusses underfeed stokers and describes apparatus by Donneley, Jones, Riley and Combustion Eng. Corp.

Underfeed. A New Underfeed Stoker (Eine neue Unterschubfeuerung), H. Pradel. Zeit. fur Dampfkessel u. Maschinenbetrieb, vol. 44, no. 37, Sept. 16, 1921, pp. 289–291, 7 figs. Details of new stoker of the Berlin-Anhalt Machine Constr. Corp. for a double-flue boiler.

STREET RAILWAYS

Track Reconstruction. Reconstruction of Toronto Street Railway System on Large Scale. Contract Rec., vol. 35, no. 47, Nov. 23, 1921, pp. 1009–1014, 15 figs. Track rehabilitation carried out by methods designed primarily for speed. Notes on steam-shovel grading, rapid pavement breaking and batch-transfer method of concreting.

STRESSES

Analysis of Internal State of. The Geometry of Progress in Structural Engineering or Euclidian Principles Applied to Stress Analysis and Volumetric Measurement of Mechanical Intelligence, C. A. P. Turner. Cem. & Eng. News, vol. 33, no. 12, Dec. 1921, pp. 19–25, 3 figs. Writer claims that during past 20 years the structural engineer has advanced little in precise knowledge of internal states of stress in elastic materials of constructing upon which their strength or resistance depends. Refers to idiosyncracies of building code provisions for shear, and inconsistencies of research work, etc., which point to backward rather than forward trend of theoretical progress.

Eyebars. The Calculation of Stresses in Eyebars (Beitrag zur Berechnung der Spannungen in Augenstäben), Josef Beke. Eisenbau, vol. 12, no. 9, Sept. 16, 1921, pp. 233–214, 7 figs. Method of calculating stress in eyebars for bridge and machine construction.

Steel Construction. Consideration of Alternating Stresses in the Proportioning of Cross-Sections in Steel Construction (Ueber die Berücksichtigung des Spannungswechsels bei der Querschnittbemessung im Eisenbau), W. Schachenmeier. Bauingenieur, vol. 2, nos. 9 and 10, May 15 and 31, 1921, pp. 33–36 and 37–38, 5 figs. Reply to inquiry addressed to German Soc. for Civil Eng. by German Industry Committee on Standards as to why, in determination of strength of bars in steel construction, alternating stresses are generally not considered.

STRUCTURAL STEEL

I-Joists. Using Steel Lumber in Building, Thomas J. Foster. Iron Trade Rev., vol. 69, no. 21, Nov. 24, 1921, pp. 1350–1352 and 1359, 5 figs. Light steel I-joists, with cross bridging, metal lath and steel accessories have been developed to take place of wood. Light weight and fire-resisting properties are chief advantages. (Abstract). Paper read before Am. Iron & Steel Inst.

Impact Tests. Fractures in Structural Steels and the Krupp Continuous Impact Tests (Dauerbrüche an Konstruktionsstählen und die Kruppsche Dauerschlagprobe), Fr. Rittershausen and P. Fischer. Stahl u. Eisen, vol. 41, no. 47, Nov. 24, 1921, pp. 1681–1690, 23 figs. Nature of permanent stress and fracture formation of a number of specimens of fractures are explained. Based on results of about 3500 separate tests on the Krupp continuous impact-testing machine, the relations between resistivity of a steel against permanent stresses and its limit of elongation, which reflects its maximum limit of elasticity, are described.

SUPERHEATED STEAM

Industrial Heating. Superheated Steam for Heating Only. Power Plant Eng., vol. 25, no. 24, Dec. 15, 1921, pp. 1199–1200, 1 fig. Describes 3,000-hp. boiler plant of Lever Bros. Co., East Cambridge. Mass.; generates high pressure steam for industrial purposes only.

T

TAYLOR SYSTEM

Civil Engineering. Organization in Public Building Work (L'organisation des travaux publics), C. Andreae. Bulletin Technique de la Suisse Romande, vol. 47, no. 24, Nov. 26, 1921, pp. 277–281, 2 figs. Discusses Taylor system and scientific management for civil engineering as against mechanical, in factories, etc.

TERMINALS, LOCOMOTIVES

Pere Marquette Ry. New Engine Terminal Facilities for the Pere Marquette Railway, at Saginaw, Mich. Ry. Rev., vol. 69, no. 24, Dec. 10, 1921, pp. 783–789, 12 figs. Details of design and construction of cinder pits and roundhouse, etc.

TERMINALS, RAILWAY

Freight. New Freight Terminal for the N.Y., N. H. & H. R. R. in Providence, R. I. Ry. Rev., vol. 69, no. 22, Nov. 26, 1921, pp. 707–711, 9 figs. Has approximate standing capacity of 4,000 cars, with yard trackage of 55 miles.

Passenger. On the Question of Terminal Stations for Passengers, A. S. Baldwin. Bul. Int. Ry. Assn. vol. 3, no. 10, Oct. 1921, pp. 1483–1526, 14 figs. Discusses arrangements for reducing movements of locomotives and empty rolling stock at passenger terminals; types of terminals: stub, through, loop and combinations; their capacity, track curvature, etc. Appendix.

TEXTILE MILLS

Electricity in. Electricity in Textile Mills. Elec. Jl., vol. 18, no. 11, Nov. 1921, pp. 486–517, 53 figs. The Central Station and the Textile Mill by F. S. Root; Modernized Plant of Prudential Worsted Co. by J. B. Parks; The Textile Industry in the South, John Gelzer; The Design of Induction Motors for Textile Service, O. C. Schoenfeld; Individual Motor Drive for Spinning and Twister Frames, George Wrigley; Motors for Textile Finishing Plants, Warren B. Lewis; Central Station Power for Textile Mills, John H. Fox; Adjustable Speed Motors and Control in Finishing Plants, C. W. Babcock; Silk Throwing and Electric Drive, C. T. Guilford; Day and Night Lighting in Textile Mills, Samuel G. Hibben.

TIDAL POWER

Installations. Tidal Power Installations (Installations marémotrices), André Defour. L'Electricien, vol. 52, no. 1287, Nov. 1, 1921, pp. 488–494, 9 figs. Describes French plant at Rotheneuf, Ille-et-Vilaine, and gives cost calculation per hp. for the different types of equipment.

TIME STUDY

Economy of Human Effort. Economy and Human Effort in Industry, E. Farmer. Eng. & Indus. Management, vol. 6, no. 19, Nov. 10, 1921, pp. 535–537. Deals with alternative choices, namely, unreconcilable hostility to study; approval of its present form; and scientific inquiry into its possibilities. (Abstract). Paper read before British Assn.

Metallurgical Analysis. Time Studies in Metallurgical Analysis, W. F. Dietrich. Min. & Sci. Press, vol. 123, no. 21, Nov. 19, 1921, pp. 708–710 Preliminary report on application of detailed time studies to instruction in metallurgical analysis in department of mining and metallurgy of Stanford University.

TOOL MAKING

Raw Material for. The Economical Size and Accurate Cost of Raw Material used in Tool Manufacture. Machinery (Lond.), vol. 19, no. 476, Nov. 10, 1921, pp. 155–159. Discusses correct diameter and length of blank, its weight, and cost per lb. of material. Gives table of weights for high-speed steels.

TRACTORS

Machining Methods. Production Methods in a Tractor Works. Eng. Production, vol. 3, nos. 57 and 58, Nov. 3 and 10, 1921, pp. 421–425, and 443–446, 22 figs. Details and equipment of factory recently laid out by Wallace (Glasgow), Ltd., for manufacture of the Glasgow tractor. Details of tractor and machining process.

TRANSPORTATION

Factory. The Analysis and Control of Factory Transportation, F. A. Pope. Factory, vol. 27, no. 6, Dec. 1921, pp. 747–751, 6 figs. Describes plan providing both for internal transportation service and that of road trucks in outside work.

TUNGSTEN

Uses. Tungsten and Its Industrial Alloys (Le tungstène et ses alliages industriels), J. Hebert. La Technique Moderne, vol. 13, no. 11, Nov. 1921, pp. 458–468. Discusses tungsten ores and extraction; ore analysis; uses of tungsten metal; ferro-tungsten; magnetic steels; high-speed steels, their properties, composition and analysis.

V

VOCATIONAL TRAINING

Germany. Industrial Training and Vocational Guidance, M. Morley. Eng. & Indus. Management, vol. 6, no. 20, Nov. 17, 1921, pp. 568–569. Outlines manner in which these are being developed in Germany as basic step towards decasualization. Most interesting of German plans is said to be the organized direction of workers from overcrowded or decaying industries to industries where their services are in demand.

W

WAGES

French and American Methods. Modern Theory of Salary (La théorie du salaire moderne), F. Bayle. La Technique Moderne, vol. 13, no. 5, May 1921, pp. 218–220. Discusses American and French methods and how they are arrived at

Reduction, Effect of. Cutting Wages the Sure Way to Retard Business Resumption, E. W. Hulet. Am. Mach. vol. 55, no. 23, Dec. 8, 1921, pp. 930–931. Study of business conditions for forty years. It is claimed that careful management makes high wages better for all.

Systems, Comparison of. Time, Piece-Rate and Premium Wage Systems (Zeitlohn, Stücklohn und Prämiensystem), H. Frydrychowics. Schiffbau, vol. 23, no. 4–5, Oct. 26-Nov. 2, 1921, pp. 105–110, 3 figs. Discusses advantages and disadvantages of different systems in shipyards and recommends a new system.

WASTE HEAT

Installation at Cement Plant. Waste Heat Installation at Cement Plant. Rock Products, vol. 24, no. 23, Nov. 5, 1921, pp. 13–17, 14 figs. Trinity Portland Cement Co., Dallas, Texas, erects waste-heat power plant at cost of over half a million dollars. Entire plant run by waste heat from kilns.

Utilization. Heating, Hot-Water Supply and Drying with Waste Heat (Heizung, Warmwasserbereitung und Trocknung durch Abfallwärme), F. Frenckel. Zeit. des Vereines deutscher Ingenieure, vol. 65, no. 45, Nov. 5, 1921, pp. 1164–1168, 15 figs. Sources of Heat. (1) Exhaust steam: Winding engines, compressors, pumps, steam hammers; advantages gained by installation of exhaust steam storage; economical utilization of exhaust steam and heating plants. (2) Cooling water: Internal-combustion engines, gas coolers, compressors. (3) Waste Heat: Internal-combustion engines, boiler plants, coke plants, industrial furnaces. Utilization of waste heat. Reconstruction of live-steam into exhaust-steam furnaces. Air heating with exhaust steam and vacuum.

WASTE UTILIZATION

Western Electric Co.'s Practice. More Dollars from Salvaged Material. Factory, vol. 27, no. 6, Dec. 1921, pp. 766–767, 3 figs. Describes how Western Elec. Co. saves $60,000 a year by changing its waste into by-products.

WASTES

Industrial, Salvaging. Salvaging Industrial Wastes, J. A. Smith. Mech. Eng., vol. 43, no. 12, Dec. 1921, pp. 797–798. Notes on salvage work in metal wastes and in maintenance and repairs.

WELDING

Metallography Applied to. Principles of Metallography as Applied to the Industry of Welding, W. H. Ludington. Jl. Eng. Inst. Can., vol. 4, no. 12, Dec. 1921, pp. 611–615, 5 figs. Outline of principles of metallography as applied to electric arc, thermit and oxy-acetylene welding.

The Vertical Triple-Expansion Pumping Engine

A Study of the Pumping-Engine Installations at Cleveland, Ohio, During the Past 65 Years—A New Record Performance at the Division Avenue Pumping Station

By L. A. QUAYLE,[1] CLEVELAND, OHIO, and E. H. BROWN,[2] MILWAUKEE, WIS.

Cleveland, Ohio's, installations during the past sixty-five years make an interesting study of both the improvement which has been made in the economy of pumping engines, and the increase in energy available to the engine which has resulted from successive increases in steam pressure and temperature. These installations also cover the period of the introduction of stoker firing and the operating records show their effect on the overall economy.

In 1917 Cleveland's new Division Avenue Pumping Station was put into service. The results of recent tests of the units of this station are given in detail in the present paper, as well as results of the official tests of all of the nine other vertical triple-expansion pumping engines in service in the Cleveland Water Works.

The authors' investigation leads them to believe that the Division Avenue station contains at least one and possibly four engines whose duty record and thermal efficiency have never been equaled by any other steam-driven pumping engine, namely 211,000,000 ft-lb. of work per 1000 lb. of steam used and 24.3 per cent thermal efficiency. They consider that the development which has led to such high efficiency in water-works steam pumping engines that require in general a maximum of not over 1500 hp., has been largely the result of the practice, instituted by water-works engineers, of making economy tests on all installations.

THE crank-and-flywheel vertical triple-expansion pumping engine originated from the designs of high-duty pumping machinery made under the direction of the late Edwin Reynolds. The first engine of this type was installed in the Milwaukee Water Works in 1886, is still in constant service, and differs but little in appearance and general design from the most modern unit. The high mechanical and thermal efficiencies of Reynolds' design were early recognized, and many elaborate and accurate tests were made on different installations. The first which attracted general attention were made by R. C. Carpenter and published in the Transactions of the Society in 1893.[3] The Reynolds design has been adopted by water-works engineers as a standard for American practice, and has been extensively copied abroad.

The introduction and adoption for general water-works service of this slow-piston-speed type of unit with its resulting enormous weight per unit of power, at a time when the whole tendency of prime-mover development was toward high speed and moderate unit weight, as evidenced by the extensive use of the Holly Gaskill type of pumping engine, the Porter-Allen high-speed general-service engine, and also the introduction of the Parsons turbine for small-generator drive, would have been impossible were it not for the very high efficiency over wide variations of capacity and head, and the great reliability inherent in pumping units of this type.

So far as the authors know, there is no record of any triple-expansion pumping engine having been wrecked or broken beyond standard commercial repair, and there are records available of engines of this type having run continuously with only a few hours' shutdown for adjustment and minor repairs for a period of over ten years.

Cleveland, Ohio's installations during the past 65 years make an interesting study of both the improvement which has been made in the economy of pumping engines, and the increase in energy available to the engine which has resulted from successive increases in steam pressure and temperature. These installations also cover the period of the introduction of stoker firing and the operating records show their effect on the overall economy.

From the standpoint of engine and boiler depreciation, the engine longest in service was Cornish No. 2, which was put in operation at Division Avenue in 1856, moved to Fairmount Station in 1885, and taken out of service in 1905, making a total of 49 years from the date of first operation until it was permanently shut down because of obsolescence. Worthington engine No. 3 was installed in 1884 and is still in service at Fairmount Station, a total of 37 years to date. The boilers longest in the Water Department service were the Cornish purchased for Division Avenue in 1872, moved to Fairmount Station in 1894, and finally dismantled in 1905, making a total of 33 years from the time of purchase until they were dismantled with the Cornish engines because of obsolescence.

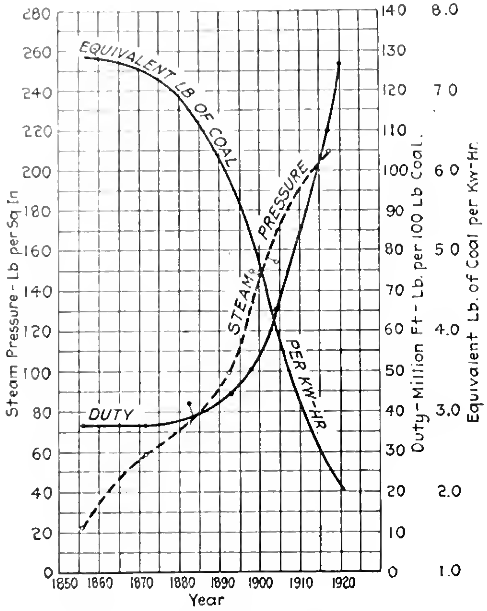

Fig. 1 Steam Pressure and Economy, Cleveland's Pumping Stations, 1856–1921, No Economizers

The effect of increased steam pressure, improvement in boiler and stoker efficiencies, and the changes in pumping-engine design have been summarized graphically in Fig. 1, which shows the steam pressure, together with the duty obtained from the different installations, plotted as a function of the time in years. It is interesting to observe that the increase in steam pressure from 22 lb. in 1856 to 80 lb. in 1883, did not result in higher duties owing to the fact that Cleveland purchased duplex pumps with the first increase in steam pressure. The purchase of this type of pump probably resulted from the low prices due to the adoption of the duplex direct-

Abridgment of paper presented at the Annual Meeting, New York, December 5 to 9, 1921, of The American Society of Mechanical Engineers. All papers are subject to revision.

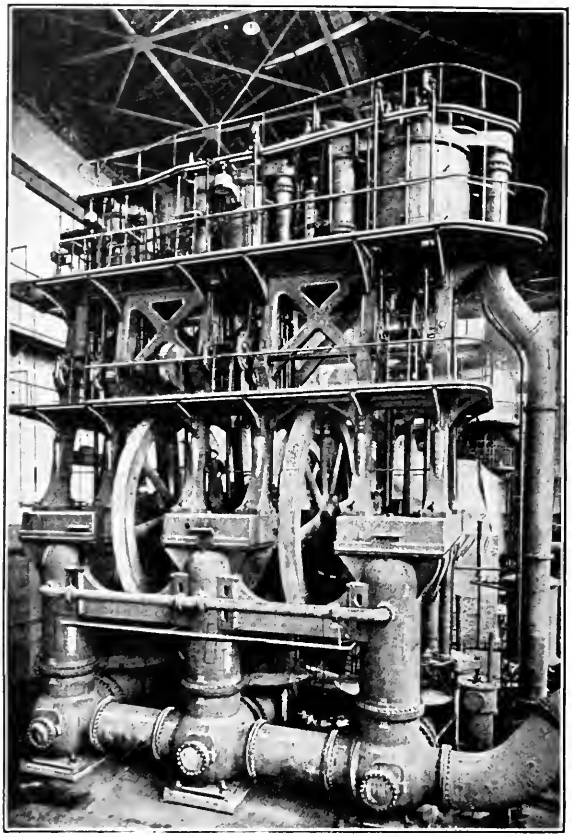

Fig. 2 Allis-Chalmers Engine No. 3 with Lagging Removed

acting Worthington design by a large number of pump builders following the expiration of the basic patents.

It is interesting to note in connection with boiler-room obsolescence that at the Division Avenue Station in 49 years of active service (1856 to 1905) there were 14 different boiler installations, making a total of 53 boilers of six different types. This station started out in 1856 with the same number of boilers (six) for a pumping-station capacity of 8,000,000 gal per day as the new station is now provided with for a capacity of 150,000,000 gal. per day.

In 1901 Kirtland Pumping Station was put in service using 155 lb. gage boiler pressure and 120 deg. superheat, and with a greatly improved boiler plant which resulted in an increased station duty per 100 lb. of coal of approximately 47 per cent as compared with the best Division Avenue Pumping Station records, although the engine duties per 1000 lb. of steam were not greatly increased, as is shown by the official duty tests listed as Item No. 71 in columns Nos. 10, 11, 14, 15, and 16 of Table 2. Eight years of progress in pumping-engine design are reflected in the increase in duty of Holly engines Nos. 6 and 7 of about 9 per cent when tested under approximately the same pressure and superheat as Holly engines Nos. 2 and 3, a portion of the gain resulting from a better vacuum due to the use of water-works-type surface condensers instead of the jet type with which Holly engines Nos. 2 and 3 were equipped.

In 1917 Cleveland's new Division Avenue Pumping Station was put into service. As far as the authors have been able to determine, the average duty of this station with a performance equivalent to 127,000,000 ft-lb. of work per 100 lb. of coal fired is not exceeded by any other coal-fired pumping plant in which the normal low cost of coal does not warrant investment in economizers. This low coal consumption is due to the use of efficient boiler and stoker equipment operated under constant engineering supervision and the use of highly efficient triple-expansion engines working under 210 lb. steam pressure and 120 to 150 deg. superheat.

Our investigation also leads us to believe that this station contains at least one and possibly four engines whose duty record and thermal efficiency have never been equaled by any other steam-driven pumping engine. The best economy obtained on any one of these four engines—211,000,000 ft-lb. of work per 1000 lb. of steam used and 24.3 per cent thermal efficiency—is compared in Table 1 with a summary published in Kent[1] of the most notable high-duty pumping-engine records.

It is instructive to compare the thermal efficiency (including auxiliaries) of 24.3 per cent obtained on the 1400-hp. vertical triple-expansion pumping engine with 24.8 per cent, the maximum thermal efficiency (excluding auxiliaries) of the Interborough Rapid Transit 45,000-hp. cross-compound turbo-generator; with 24.1 per cent, the maximum thermal efficiency obtained by any one of four 40,000,000-gal.-per-day low-head 300-hp. Humphrey gas pumps at Chingsford, England; and also with the 24.1 per cent thermal efficiency obtained on a 1500-hp. natural-gas-engine generating unit of the American Locomotive Co. at Allegheny, Pa., as it shows that these four distinctly different types of units have all reached a point of development at about the same time at which they give practically the same thermal efficiency. This would seem to indicate that any large improvement in the future of any one type must call for a radical departure from the present trend of development.

The foregoing comparison of records made by different types of units emphasizes the relatively small horsepower of the pumping engine. The authors consider that the development which has led to such high efficiency in water-works steam pumping engines that require in general a maximum of not over 1500 hp., has been largely the result of the practice, instituted by water-works engineers, of making economy tests on all installations.

The rebuilding of Division Station which resulted in the economies referred to included the installation of three new Allis-Chalmers units, two of 25,000,000 gal. per day capacity against 250 ft. head and one of 20,000,000 gal. per day capacity against 380 ft. head.

TABLE 1 COMPARISON OF ECONOMY RECORDS AS GIVEN IN KENT'S HANDBOOK WITH DIVISION AVENUE STATION SPECIFICATIONS ADDED

Date of test	1899	1900	1900	1901	1906	1915	1918	1918
Locality	Wildwood, Pa.	St. Louis, Mo.	Boston, Chestnut Hill	Boston, Spot Pond	St. Louis, Bissell's Point	Cleveland, Division Ave.	Cleveland, Division Ave.	Cleveland, Division Ave.
Expansion	Quadruple	Triple	Triple	Triple	Triple	Triple	Triple	Triple
Figures based on	Test	Test	Test	Test	Test	Specifications	Test under specifications conditions	Test using receiver heater
Ft-lb. of work done per million B.t.u consumed	162.9	158.07	156.8	156.59	158.85	170	170.3	189.2
Corresponding thermal efficiency, per cent [1]	20.95	20.32	20.15	20.13	20.42	21.95	22.61	24.27
Equivalent B.t.u. per kw-hr.,[2] including all condenser and other auxiliaries	16280	16780	16930	16940	16700	15600	15070	14030

[1] The thermal efficiency in water-works practice is computed from an actual mean condensate temperature and not on the assumption that the condensate leaves the engine at the temperature of the exhaust steam, and also includes the power required for all the engine's auxiliaries.

[2] = 2,654,200 ÷ Ft-lb. of work done per million B.t.u. consumed.

---

[1] Mechanical Engineers' Pocket-Book, 9th Edition, p. 806.

The specifications for these units called for a duty for each of not less than 170,000,000 ft-lb. of work for each million heat units consumed when supplied with steam at 200 lb. gage pressure and 100 deg. fahr. superheat and with only exhaust steam used for feedwater heating.

The results of the tests of the new Division Avenue units are given in detail in the first four columns of Table 2. The other columns present the results of the official tests of all of the nine other vertical triple-expansion pumping engines in service in the Cleveland Water Works.

The economy of all the units covered in the test results in Table 2 is indicative of the efficiency of this type of engine when built in a wide range of sizes—the smallest being Holly engines Nos. 4 and 5 of 155 hp. and the largest, Allis No. 4 of 1400 hp.—and operated under greatly different steam conditions, and is also indicative of the excellence to which the design has been brought by the different builders.

The performance of Allis engines Nos. 2, 3, and 4, previously referred to can be taken as applying in general principle to the vertical triple-expansion type of pumping engine, and the following interesting developments which were brought out by an analysis of the test results bear on certain characteristics the authors believe are worthy of special consideration.

As the major loss in efficiency ratio is due to incomplete expansion in the low-pressure cylinder, it follows that the efficiency ratio should increase rapidly if this loss is reduced by increasing the exhaust pressure. This conclusion is confirmed by the results of a series of variable vacuum tests plotted in Fig. 3. These tests show that the efficiency ratio of the steam cylinders increased from 73 per cent at 0.725 lb. per sq. in. (28.52 in. vacuum) to 83 per cent at 1.75 lb. per sq. in. (26.44 in. vacuum). The thermal efficiency of the Rankine cycle has also been plotted for comparison with the theoretical thermal efficiency of a constant mean-effective-pressure (or incomplete expansion) cycle having a m.e.p. of 23 lb. per sq. in. This m.e.p. approximates the loading during the tests being discussed. The theoretical thermal-efficiency-ratio line on the diagram shows the effect of incomplete expansion on the efficiency ratio of a constant m.e.p. cycle and illustrates how closely the characteristics of the actual engine conform to those of the ideal.

The form of the efficiency-ratio exhaust-pressure curve in Fig.

45. Velocity of flow ft. per sec. through discharge pipe,	3.216		4.018		1 374	4 374	3 15	4 02		4 02		3.940				

3 is characteristic of the type of engine as well as of the particular unit tested. This characteristic is shown by the tests of seven Cleveland engines plotted in Fig. 4 in which the vacuum varied over a wide range.

The efficiency ratio of the high-pressure and intermediate-pressure cylinders combined, which operate, in effect, as a noncondensing compound, is 83 to 85 per cent, with the high-pressure cylinder alone attaining an efficiency ratio of 90 per cent. These high efficiencies result from the loss, due to incomplete expansion, which is so large in the low-pressure cylinder, being reduced to a minimum for the two higher-pressure cylinders, and from the use of an amount of superheat in the high-pressure cylinder which results in the steam being exhausted at approximately dewpoint.

The bleeding of approximately 8 per cent of the steam used from the second receiver at about atmospheric pressure, and its utilization for heating feedwater, increases the thermal efficiency of the unit approximately 7 per cent and is accomplished with no increase in steam consumption, for the reason that the loss of available energy of 3 per cent in the bled steam is offset by an increased efficiency of the cylinders due to the resulting better distribution of the work between them. This alteration in the efficiency characteristics is better visualized by considering that when the engine is operated without second-receiver bleeding, the intermediate-pressure cylinder is considerably underloaded and the low-pressure cylinder is heavily overloaded and that these conditions of cylinder loading are bettered by the withdrawal of steam from the second receiver for heating purposes.

The performance of the different elements of the steam end

which enters into the characteristics summarized, can be estimated with accuracy from the test data for unit No. 4, and such an examination also discloses the effect of the second-receiver feedwater heater used during the October 15 test. This feature may be of general interest at present because of the attention the subject of stage heating of feedwater is receiving from central-station engineers. The steps followed in analyzing the tests of October 14 and 15, 1918 are described below.

The efficiency ratio of the high-pressure cylinder and jacket is obtainable from the indicated horsepower, the total steam used, the initial steam pressure and superheat and the first receiver pressure, which is the exhaust pressure for that cylinder. The average quality of the steam leaving the high-pressure cylinder and jacket with correction for estimated radiation is therefore known, but because of the arrangement of steam flow in which the condensed steam from the high-pressure jacket is discharged direct to the second receiver without being measured, the quality of the steam in the first receiver is not readily estimated. The high-pressure and intermediate-pressure cylinders' economy is estimated from the sum of their indicated horsepowers, the total steam used, the initial steam pressure and superheat and the second-receiver pressure. As all the steam is brought together again in the second receiver, the quality at this point, with allowance for radiation, is determined with accuracy.

The receiver volumes are very large and they become effective separators, as is evidenced by the large percentage of drain water discharged from the second receiver. An assumption of the complete separation in the second receiver affords a means of estimating the performance of the low-pressure cylinder and jacket, and any error involved in such an assumption has very little effect on computed efficiency ratio.

From the test data of October 15 (including the temperature rise of the condensate through the second receiver heater) the amount of steam withdrawn from the receiver for condensate-heating purposes is readily determined.

The economy of the different cylinders during the October 14 and 15 tests and the distribution of work between the cylinders are given in Table 3, with sufficient detail to illustrate the methods used in arriving at the different results. The results of the analysis of these two tests are also plotted in the form of a Mollier diagram in the complete paper.

The remarkable flatness of the efficiency curve of the vertical triple-expansion type of pumping engine under a great variation of conditions is shown by the curves in Fig. 5, in which the percentage of duty is plotted against variable speed and variable head. The loss in economy is only 5 per cent at half load and 6 per cent at half speed, with flat characteristics on the overload side also.

In view of the high efficiencies attained by this type of unit under all the operating conditions of steam pressure, superheat, vacuum, speed and load, it is felt that some particulars regarding the gen-

eral features of cylinder construction and arrangement, the type of valve gear, and the system of steam flow through the engine will be found of interest.

The steam cylinders are jacketed, a jacket for each being supplied with steam at the initial pressure for that cylinder.

The high-pressure cylinder has Corliss admission and exhaust valves. The intermediate-pressure cylinder has Corliss admission valves and single-beat poppet exhaust valves. The low-pressure cylinder has single-beat poppet admission and exhaust valves. The valves for all cylinders are located in the cylinder heads with the poppet valves flush with cylinder-head surface when closed. The types of steam and exhaust valves used, Corliss and single-beat poppet, insure tightness when good workmanship and a detailed design that minimizes distortion under temperature changes are employed. The location of all steam valves in the cylinder heads reduces the cylinder clearance to a minimum, as may be judged from an inspection of Table 4.

The slow speed and great dimensions of the steam cylinders and receivers result in the exposure of a large cylinder and receiver surface per 1000 lb. of steam used, but as a result of the thorough covering with a high-grade non-conducting material and the enclosing sheet-metal lagging, the loss of radiation is very small. An estimate of this loss, using generally accepted coefficients of heat transmission, indicates that not more than 1 per cent of the total steam is condensed by radiation.

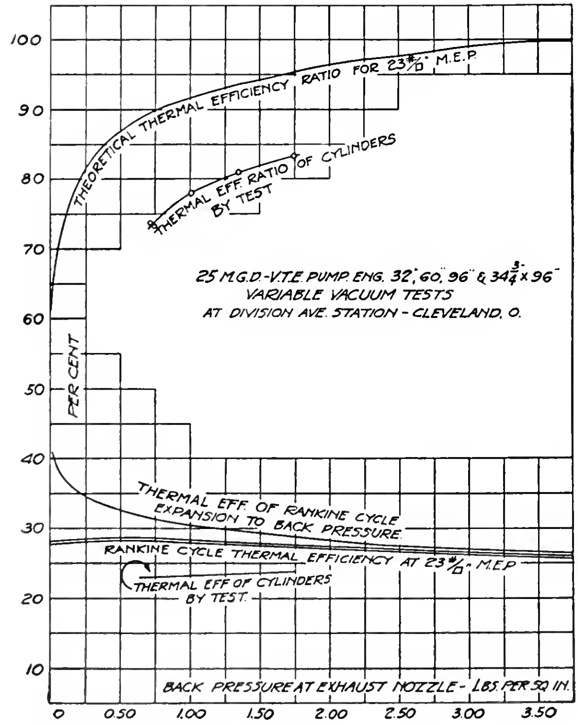

Fig. 3 Variable Vacuum Tests at Division Avenue Station, Cleveland, Ohio

The condensed steam from the high-pressure cylinder jacket is discharged through a trap to the second receiver space. The condensate drain from all the first receiver spaces and from the intermediate-pressure cylinder jacket is likewise discharged through a trap to the second receiver. All of the condensed steam from the second-receiver low-pressure cylinder jacket, and the second-receiver feedwater heater, when it is in service, is discharged through a single trap to atmospheric pressure. The temperature of the water thus discharged to the atmosphere does not at any time exceed 200 deg. fahr.

The steam exhausted from the low-pressure cylinder is condensed in a water-works type surface condenser (the steam flowing through the condenser tubes in two passes) located in the main suction pipe directly adjacent to the pump chambers.

The condensate is removed from the condenser by a single-acting bucket-type wet air-pump driven direct from the low-pressure plunger head and discharges into a tank from which it is pumped through the exhaust-steam heater to the station feedwater heater by a single-acting condensate pump direct driven from a main-pump plunger-head. The exhaust-steam heater is located in a by-pass connection of the main exhaust pipe just ahead of the condenser.

DISCUSSION OF PAPER ON VERTICAL TRIPLE-EXPANSION PUMPING ENGINE

AS SUPPLEMENTARY data Leonard A. Day[1] submitted the results of a more recent test on the Holly engine at Bissell's Point Station than that referred to in Table 1. The duty in ft-lb. per B.t.u. was 166.7, and this was raised to 169.3 by installing an exhaust heater. Assuming the ratio of the thermal efficiency of the unit to that of the ideal Rankine cycle not to vary for an increase in the steam conditions from those in the test to those of A. C. pump No. 4 of the Cleveland tests, then the increase in duty would be in direct proportion to the increase in the Rankine-cycle efficiency, an increase of 4.8 per cent. The resultant duty would be 169.3 × 1.048 = 177.5, or a duty comparable with that of the Cleveland A. C. pump No. 4. The overall thermal efficiency of the unit including exhaust heater is 21.8 per cent for the steam conditions of the test, and 22.8 per cent for the steam conditions of A. C. pump No. 4 of the Cleveland tests.

TABLE 4 AVERAGE CYLINDER CLEARANCES, DIVISION AVENUE UNIT NO. 4

Cylinder	Diameter, inches	Stroke, inches	Cylinder clearance volume, per cent of piston displacement
High-pressure	36	66	1.50
Intermediate-pressure	68	66	0.50
Low-pressure	108	66	0.25

E. E. Miller[2] said that some years ago he plotted a temperature-entropy diagram from an Allis-Chalmers engine in St. Louis during one of the official tests, which showed up very clearly the loss due to expansion in the low-pressure cylinder: that is, the fact that it could not be carried out as far as they would have liked to carry it out, as mentioned in the paper.

A. G. Christie[3] said that he did not believe any turbine-driven centrifugal pump could approach the 77 per cent overall Rankine-cycle efficiency given in item 66 of Table 2 for the Allis-Chalmers No. 4 pumping engine. Recently, at one of the largest pumping plants in the country he had seen an engine that had not been overhauled for extensive repairs since it was first put into service in the 70's. He doubted whether a turbine installation would operate for a similar length of time without rebuilding and considerable renewal of parts.

In reply to a question put by the chairman of the session, Past-President Jacobus, George A. Orrok[4] said that reciprocating engines and exhaust-steam turbines could be combined so as to give remarkably good results. The cost, however, would be another matter. The proposal had been made to put in a reducing gear between the turbine and the pump, and while in naval practice the reduction gear was said to be giving satisfactory service, there were nevertheless some who did not quite fancy its employment.

By and large, he would say that the best efficiency in pumping water would be gotten out of a reciprocating engine with the proper arrangement for using the heat in the receiver. As to money economy, that was different. Large pumping engines now cost from 8 to 8.5 cents per lb. and turbines all the way from 50 cents to $2 per lb. While ordinary centrifugal pumps cost about the same as engines, those of an efficiency approaching 90 per cent would probably cost from 25 to 30 cents per lb.

Referring to the paper, he regretted that the author had employed the Mollier diagram to show the performance of the engine instead of the better and simpler temperature-entropy diagram.

Frank L. Fairbanks[5] asked what the drop in efficiency of large-size water-works centrifugal pumps would be in a given period. He had had experience with centrifugal pumps in pumping refrigerating brines and salt water and knew that in such work the efficiency held up less than six months and that the average life of an impeller in salt water was less than a year. At Buffalo tests showed that in less than 18 months the drop was prohibitive, and in putting in new equipment the water-works company went back to the reciprocating type of equipment.

George H. Gibson,[6] replying to Mr. Fairbanks said that two large

Conservation of Timber Supply

Addresses Delivered at the A.S.M.E. Annual Meeting and Dealing with Reforestation for the Purpose of Community Perpetuation, and the Manufacture of Paper and By-Products from Southern Pine Refuse

Two important phases of the problem of conserving the timber supply of the country were discussed at the Forest Products Waste Session of the A.S.M.E. Annual Meeting in December, Thomas D. Perry presiding. David L. Goodwillie, chairman of the U. S. Chamber of Commerce Committee on Conservation and Reforestation, gave details of the reforestation plans that had been followed out at Bogalusa, La., whereby a continuous supply of stumpage is insured that will furnish the raw material needed to keep the industries of the town in active operation.

Mr. Goodwillie was followed by Joseph H. Wallace, of the firm of Joseph H. Wallace & Co., Industrial Engineers, New York City, who spoke on the wasteful methods that had hitherto obtained in the resinous pine districts of the South—and the particularly harmful practice of tapping turpentine from the living tree thereby probably causing its death—and told of a combination of processes involving distillation, extraction and paper making that had been developed and put into successful operation, whereby every part of the stump and logging refuse can be utilized in an efficient manner. The texts of these two interesting addresses immediately follow.

Reforestation to Conserve Industrial Investments

By DAVID L. GOODWILLIE,[1] CHICAGO, ILL.

Reforestation for the purpose of perpetuating our timber supply for future generations, for enhancing the beauty of our landscapes, for insuring a continuous supply of lumber for commercial uses and for preventing the denuding of lands and the consequent deterioration of their reproductive qualities, are well-known appeals of substantial merit.

Example of Long-Leaf Yellow Pine from 3 to 10 Years Old, Fenced About 10 Years; Natural Reproduction

The perpetuation of the timber supply for the purpose of conserving industrial and municipal investments is a new and forceful argument that is well exemplified by the far-seeing plans of the Goodyear interests at Bogalusa, Louisiana. Some sixteen years ago a man of vision, W. H. Sullivan, pitched a camp in the woods and as his vision crystallized into accomplishment, there grew the sawmill of the Great Southern Lumber Co., and the New Orleans, Great Northern Railroad connecting this sawmill with the market. A little later the Bogalusa Paper Company came into being, converting much of the sawmill and stump-land waste into Kraft paper and pulp-board.

In addition to the foregoing is a hardwood sawmill, a veneer mill, many miles of logging road and other associated and affiliated industries.

The visions of the founder of Bogalusa were clear enough to foresee the time when all of the above mentioned industrial developments, together with the homes and cottages, paved streets, parks, hotels, clubs, schools and churches, would disintegrate into a pine barren if proper provisions were not made for a continuing supply of stumpage that would furnish raw material to keep the wheels of Bogalusa's industries turning.

It has been one of the undisputed principles of American existence that until visions are entrenched behind economic facts they seldom materialize into actual accomplishments. A realization of this caused the Goodyear interests under the leadership of W. H. Sullivan, manager of the Great Southern Lumber Co., to begin early to solve, first, the problem of protecting the native seedling on cut-over lands from fire and hogs, and second, the best method of planting new varieties of trees. This was followed by experiments in transplanting both the nature-sown and hand-sown product, to determine how to produce merchantible lumber quickly. The result is seen in the twelve- and fourteen-year stands of pine shown in the accompanying illustrations where the young trees are approaching a point of usefulness for paper making and giving promise of merchantible sawmill timber in thirty to fifty years, according to variety.

"The growth of the most rapidly growing seedling tree," says Mr. Courtenay DeKolb in a recent article, "averages about half an inch in diameter per year, producing a four-inch tree in eight years, a fifteen-inch tree in thirty years, and a twenty-inch tree in forty years. During the period from germination to the eighth year the lands may be profitably occupied in grazing. It will take 30 years for most of the lumber companies on our line to cut out the present virgin tree crop, and by that time our fifteen-inch second-growth trees will be ready for the saw, thus insuring an uninterrupted continuation of our great wood industries."

The method of encouraging nature in her seed scattering is interesting. "Preceding the axe and saw," continues Mr. DeKolb, "goes the forestry man, and he selects and rings in white paint, at least three good seed trees to the acre. These marked trees are spared and preserved as the progenitors of our future forests. The undersize trees left by the sawmill make good pulp wood to start with. Under their genial sun, ample rain and almost uninterrupted growing season, the new growth comes along, and in eight years the land is ready to be culled for wood for pulp, leaving the extremely promising trees for lumber. Thus judicious thinning of the trees for pulp wood goes on until 75 or 80 excellent lumber trees are left on the acre."

Another incentive to tree culture, according to Walter S. Ayres, is being held out by a wise statute enacted in Louisiana which enables any one owning land suitable for reforestation and assessed at a valuation not in excess of $10 per acre to enter into a contract

---

[1] Chairman, U. S. Chamber of Commerce Committee on Conservation and Reforestation.

with the state for periods ranging from 15 to 40 years, as desired, whereby the landholder obligates himself to reforest under the general advice and direction of the Forestry Division of the State Department of Conservation, and the assessment valuation of such land then remains fixed during the period of the contract.

"Many years ago," says Mr. Ayres, "Louisiana enacted a law that should serve as a model for every Southern state. It permitted a reforestation contract that automatically fixed the valuation of such land at $1 per acre for the period of the contract up to 40 years. This law was in advance of the times and comparatively few took advantage of it. Among those who were wise enough to do so was Henry E. Hardtner of Urania. As the liberality of this statute was not appreciated, it was modified so that now the average fixed valuation under such a reforestation contract is $5 per acre. This is rather high. A return to the $1 basis would be better, accompanied by a soil survey when application for exemption is made, so that it should apply to lands more valuable for tree culture than for general farming."

The demonstration has gone far beyond the experimental stage, and has proved adequately that the obliteration of sawmill towns at the expiration of the cutting of virgin timber is an industrial waste that has no justification in the economies of modern life and the conservation of natural resources.

A wealth of useful information on the kinds and varieties of pine trees best suited to protection, planting and transplanting is now available and the harder and rugged varieties are known and used. The present worth of the millions invested in the industrial development of Bogalusa have increased over 50 per cent by the practical demonstration of these plans for perpetuating its raw-material supply.

We Americans are conspicuous for our wonderful visions, but we seldom reduce these visions to as useful or practical a plan as is evidenced in what the Goodyear interests have done at Bogalusa.

Progress of Reforestation by Natural Seeding; the Young Trees are Seedlings from the Parent Trees Seen in the Picture

Paper and By-Products from Southern Pine Refuse

By JOSEPH H. WALLACE,[1] NEW YORK, N. Y.

THE lumberman and naval stores operator have been for years destroying the resinous pines of the South with reckless extravagance. Only about one-third of the tree ever reaches the market in the form of lumber, lath, or shingles, while a few years of the wasteful American methods of tapping turpentine from the living tree are sufficient to cause its death.

For three-quarters of a century engineers, chemists, and business men have endeavored to devise means to unlock this storehouse of wealth. This effort of inventive genius has been directed along three distinct lines. The first to be undertaken was the destructive distillation of the stump and trash wood. This produced tar, pitch, and charcoal having sufficient value to offset a portion of the cost of clearing the land. These processes have recently developed and have become moderately profitable, particularly on account of the value of flotation oils for use in the mining industry.

The second scheme for reclaiming this wealth was the cutting of the wood into fine chips, then steaming them in a closed vessel under sufficient pressure to distill off the turpentine—the steamed wood then being dried and used for fuel. This became profitable when it was found that after steaming, the wood could be used as a source of supply of rosin by extraction with a solvent. This modified plan, known as the "steam and solvent process," is now operated successfully in many locations.

The third proposal was an undertaking to utilize the fiber of the wood for making pulp and paper. This could be done only with difficulty by the acid pulp methods common to the industry, because of the extremely resinous nature of the wood.

These three methods, each commercially successful, do not recover a large percentage of the potential wealth of the stump and logging waste. Both the destructive distillation and the steam and solvent methods result in the destruction of the fiber, on which the pulp and paper manufacture depends, whereas, the value of the fiber is as great as that of all the other products.

The above methods for utilization of this material have been combined in a well-balanced combination of processes, which will utilize every part of the stump and logging refuse in an efficient manner.

A preliminary treatment will take place in semi-portable field plants which will produce turpentine, pine oil, rosin, pyroligneous acid, and tar—as well as a main product—pulp chips, of a uniform moisture and resin content.

Pulp and paper plants may be located where manufacturing and labor conditions are most favorable and where conditions justify large outlay of capital investment.

At the field plants the chips will be sorted into—

- *a* Material suitable for pulp making
- *b* Material physically unsuitable for pulp making, either because of partial decay or containing too much knot or imperfect material, and including bark, sawdust, etc.

The material unsuitable for pulp manufacture (termed "trash") will be used as raw material for destructive distillation, producing in addition to the usual acid, flotation oils, etc., a fuel supply sufficient for all of the requirements of the field plant.

No more complicated apparatus is required than is found in the average sawmill, and no labor more skilled. The method involves only the performance of work. Turpentine, pine oil, and rosin of high grade are extracted from the pulp chip before it is delivered to the pulp mill, and incidentally the character of the main product, the chip, is so modified as to make it a new article—a Standardized Chip. A chip that is uniform in rosin content, acid content, and moisture content is now available for the first time in the history of chemical pulp manufacture. The use of a standardized material for pulp making will result in increased yield, and a superior quality and uniformity of pulp.

The average yield per acre of cut-over Southern pine lands in East Texas as determined by numerous surveys, is

$7\frac{1}{2}$ cords pulp wood
$4\frac{1}{2}$ cords trash wood.

As a result of the combined operations now proposed, and by methods hereinafter described, each acre of stump and woodlands cleared has a potential wealth shown in Table 1.

---

[1] Joseph H. Wallace & Co., Industrial Engineers.

Table 1 is based on actual quantities shown to be commercially available from material cleared from a typical acre of cut-over pine land, and on the average value of the products during the first half of 1921.

In taking a bird's-eye view of this prospective empire of industrial development, the thought naturally occurs that there are eleven competitive areas, each with an outlet through a deep-water port, viz., Wilmington, N. C., Charleston, S. C., Savannah and Brunswick, Ga., Jacksonville and Pensacola, Fla., Mobile, Ala., Gulfport, Miss., New Orleans and Lake Charles, La., and Beaumont, Sabine or Galveston, Texas.

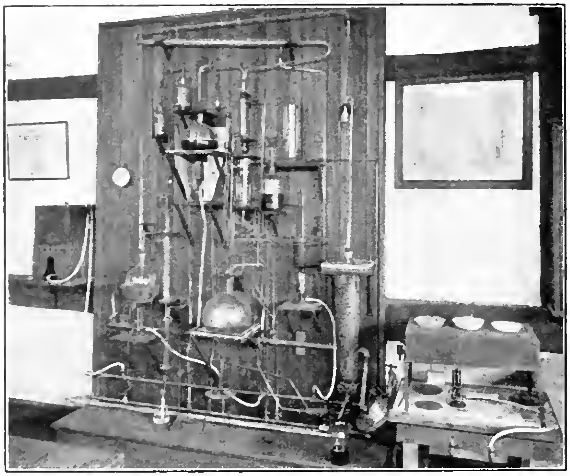

Fig. 1 Laboratory Extraction and Refining Plant

The project under consideration contemplates a preliminary treatment of material at or near the point of its origin for the extraction of by-products of a non-cellulose character, and it is believed that the cost of preparing the material for paper making, including the extraction of resinous material, would be commercially justified without regard to the utilization of trash wood or the land values necessarily increased by the removal of the wasted material therefrom.

TABLE 1 VALUE OF PRODUCTS ON AN AVERAGE ACRE OF CUT-OVER PINE LANDS IN THE SOUTHERN STATES

Pulp and Paper Plants		
Kraft, 3 125 tons at 120 (7½ cords, 4.18 tons of paper per cord)		$375.00
Extra tion Plant		
Turpentine, 49.2 gal. at $0.60 (6 cords, 8.2 gal. per cord)	$29.52	
Pine Oil, 40 8 gal. at $1 48 (6 cords, 6.8 gal. per cord)	60.38	
Rosin, 9.9 bbl. at $5.83 (6 cords, 1.65 bbl. per cord)	57.72	
		147 62
Distillation Plant		
Turpentine, 18.0 gal. at $0 57 (3 cords, 6.0 gal. per cord)	$10.26	
Pine Oil, 12.9 gal. at $1.30 (3 cords, 4 3 gal. per cord)	16.77	
Tar Oils, 6.19 gal. at $0.275. (3 cords, 2.73 gal. per cord)	1.70	
Pitch, 1755 lb. at $0.0395 (3 cords, 585 lb. per cord)	69.32	
		98.50
Total per acre		$620.67
Fuel and Solvent[1]		

[1] Values not incuded.

The locations for wood-preparing and extraction plants must have—

1 Suitable water supply
2 Transportation
3 Convenience to territory to be cleared and to existing sawmills.

By locating field plants at sawmill locations, the operations will be assured of large amounts of pulp material from slabs, edgings, etc., while the scheme for land development is under way.

Because of great variation in the oleoresin content there is much of the pine waste which cannot be profitably exploited either by destructive distillation or by extraction, but which can be economically converted into pulp. On the other hand, a considerable portion of the stumps and other pine waste, while rich in resin, is so damaged by fire and rot as to be unfit for use either in the pulp mill or extract plant. Fibers that are scorched or decayed are too weak to make good pulp, and the charcoal adhering to burnt wood darkens the color of the rosin obtained by extraction, making this product less valuable. There exist three classes of wood corresponding to the three methods of utilization:

1 Charred and rotten wood fit only for destructive distillation
2 Lean wood good for pulp but not profitable for extraction
3 Fat lightwood, rich in oleoresins, a good raw material for the steam and solvent process.

By a suitable coördination of the extraction with the pulping operation in which the latter assists in the recovery of solvent, it becomes possible to overcome the difficulty in extracting pulp-size chips, and to obtain both oleoresins and paper pulp from the fat lightwood. This combination answers the requirements set forth above. Pulp manufacture is the main object, and any additional revenue derived from the oleoresin products is pure "velvet."

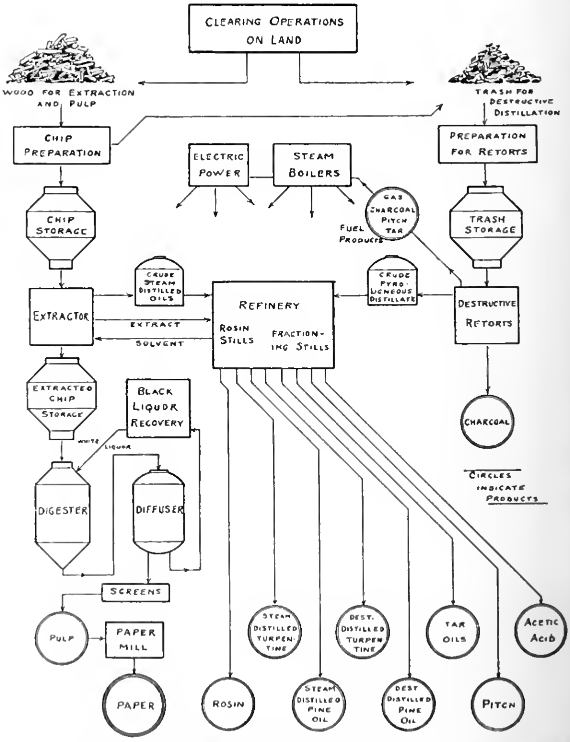

Fig. 2 Diagram Showing Manufacture of Pine Products from Waste of Cut Over Lands

One great advantage in choosing pulp and paper as the main product lies in the fact that this material can be sold on a generally stable market, while the naval stores market is notoriously speculative. So little capital is required to engage in turpentine operations that any rise in prices is quickly followed by an influx of small-scale operators, resulting in overproduction to the detriment of the trade.

In the experimental research work on the yellow-pine refuse, a miniature extraction and refining plant was first constructed from standard pieces of laboratory glassware, substantially as shown in Fig. 1.

After several modifications resulting from actual operation of this miniature plant, the process was sufficiently perfected to warrant tests on a larger scale. Accordingly a semi-commercial mill was built alongside the laboratory.

As a result of a series of tests in this miniature mill, the processes and methods mentioned have been thoroughly demonstrated.

Stresses and Deformation in Flat Circular Cylinder Heads

By GILBERT DUDLEY FISH,[1] NEW YORK, N. Y.

An analysis covering homogeneous elastic disks, where form and loading are symmetrical with respect to all diameters, where the loading is a combination of fluid pressures and of forces acting normally on concentric circles, where the thickness is uniform, and where all strains are within limits of true elasticity. Formulas applicable to all cases considered in the paper are developed, and equations are given for the constants of integration involved in the mathematical analysis. Two typical cases of the application of the principles involved have been analyzed and the results presented diagrammatically. To facilitate the computation of critical stresses and deflections in cases commonly occurring, simplified formulas are presented which may be solved by the use of charts from which certain terms are derived.

THIS paper is a mathematical analysis of stress and strain, and contains no discussion of the merits of the physical laws on which it is based. It adopts the conception of internal stress as a dependent function of strain, quite distinct from internal force which follows the laws of equilibrium; it considers that internal stress, as distinguished from internal force, is the criterion for resistance.

The field in which this analysis is intended to be useful is the design of large cylinder heads to withstand high pressures. Boiler practice, dealing with light plates and moderate pressures, provides no formulas or other guides which may be used properly in cases of pressures as high as one ton to the square inch, or of heads one foot or more in thickness. The futility of applying empiric formulas or other approximations of unknown latitude, in the design of a cylinder head which is to cost thousands of dollars, and the failure of which might cause immense damage, becomes apparent when it is discovered that in many familiar cases the values of critical stress, as given by various commonly employed methods or formulas, run as low as one-half or as high as double the values obtained by rigorous analysis.

A feature of this analysis which is thought to be of special importance is the treatment of a cylinder head having a central hole. Such a hole, even if small, has a tremendous effect on the critical stress.

While the study of the elastic deformation of a head is necessary preliminary to the determination of stresses, it is not for this reason alone that the analysis of deformation is important; the effectiveness of a gasket, depending as it does on residual gasket load, is directly related to the deflections of the head at the gasket circle before and after application of the working pressure.

It is thought proper to answer in advance an objection which may be raised against the formulas resulting from this analysis. In case it be attempted to check some of the stress formulas, by using them to calculate the maximum intensity of tensile or compressive stress in a plate or cylinder head which is known to have failed under a certain loading, a highly erroneous result is to be expected. This analysis is confined to the conditions existing in a body which is not strained beyond the limit of true elasticity at any point. The physical laws connecting strains and forces are not even approximately true outside the limits of elasticity, and the internal stresses, unlike those in a simple beam, are dependent on deformation. Therefore this analysis does not yield formulas whereby the ultimate resistance of a disk may be predicted. It is important that the strains in any cylinder head should not exceed the limits of elasticity, and it is consequently not essential to know what loading would cause it to crack or burst. In design, there must be established limiting intensities for stresses of tension, compression and shear, all well within the respective limits of elasticity for the material at whatever temperatures may be expected.

While it is not within the scope of this paper to make recommendations in regard to practice, it is thought proper to discourage the use of the ultimate strength of a material (whether in respect to tension, compression or shear) as a criterion for the maximum permissible stress in practice. Either the elastic limit or the fatigue limit is preferable as a criterion, especially in case of a special alloy steel or other material for which there exists no standard practice in regard to working stresses.

Attention is invited to the relatively large effect of detrusive (shearing) strain on the deformation of a thick head. Whereas, in the case of a boiler head, the deflections due to detrusive strain are minute in comparison with those due to flexure, they may even exceed those due to flexure in the case of a cylinder head designed to withstand several tons to the square inch, especially if there be a hole through the head.

Reference is made to the mathematical treatment of flat circular plates, by Prof. F. Grashof of Carlsruhe, published in his Elastizität und Festigkeit. There is believed to be no flaw in his analysis, and the present study, originally made without reference to his work and from a somewhat different method of approach, gives results identical with his, in so far as the same ground is covered by both. However, modern industrial apparatus involves conditions quite different in degree, if not in principle, from those contemplated by Professor Grashof, so that his formulas cannot, without a great deal of mathematical work, be extended so as to apply to actual cylinder heads. For example, it is necessary to analyze shear deflection, which was of no importance when pressures did not exceed a few hundred pounds to the square inch. Again, in the case of high pressure, surface application of load, as contrasted with distribution of load throughout the mass, appreciably reduces compressive stresses and deformation, and should be considered. The only special cases for which Professor Grashof published resulting formulas (i.e., formulas which can be used by direct substitution of numerical data), are very elementary cases which are never even approximately realized in the type of apparatus here considered. It will be found, therefore, that only a small part of this analysis is concerned with ground already covered in the work referred to. If part or all of the remainder duplicates anything previously published, the author can only plead ignorance.

Preliminary Explanation

Hooke's law, and Poisson's principle of constant ratio between lateral and longitudinal strains, are used as bases for this analysis. It is further presupposed that the elastic properties of the material are the same at all points and in all directions; also that elements (lines of particles), which in the absence of strain are straight and normal to the neutral surface, do not suffer curvature or obliquity due to flexure within the limits of elasticity, but do become curved and oblique to the neutral surface due to detrusion alone.

To define the general case to which this analysis is applicable, the initial presumptions are set down as follows:

a The head is of uniform thickness throughout

b The head is simply and uniformly supported around a circle. The familiar case of fastening by means of bolts, closely and uniformly spaced around a bolt circle, there being clearance between head and flange, is nearly a perfect realization of this assumption, except in respect to the unimportant direct stresses near the bolt circle; the shearing stresses at the bolt-circle section, which may be critical, are closely approximated by the formulas if the bolt-hole area be deducted from the gross area of the section. The design of a cylinder head may sometimes suggest fixation of the head at the support, as in the case of a head bolted tightly against a flange; however, in high-pressure work such fixation cannot actually exist, for no bolts are so inextensible as to prevent the slight angular strain which destroys fixedness, although a small degree of restraint may be imposed. Therefore fixed heads are ruled out of considera-

[1] Consulting Engineer, 101 Park Ave., formerly Major of Engineers, U. S. A.

Abstract of paper presented at the Annual Meeting, New York, December 5 to 9, 1921, of THE AMERICAN SOCIETY OF MECHANICAL ENGINEERS. All papers are subject to revision.

tion as non-existent in fact, although it is not difficult to analyze the stresses and strains which would exist in such heads. Partially fixed heads are also excluded, for one reason because it is not possible to estimate the degree of fixedness in any given case, and for the other reason because such manner of support is considered bad practice, there being no known means for combining it with a gasket or other device so as to make a joint tight against high pressure.

c The head may be solid (i.e., have no perforations other than bolt holes); but, if not solid, it has only a single central hole of uniform circular bore, concentric with the bolt circle. If there be such a hole, no matter how it may be plugged, stuffed or capped, the head is considered unrestrained aroung the hole, for the same reasons for which it is considered simply supported around the margin, on the ground that no pipe, rod, cap or other device can have more than a slight restraining effect. Any slight degree of fixedness which may actually exist reduces slightly the direct stresses, and reduces still more slightly the deflections. See Fig. 1.

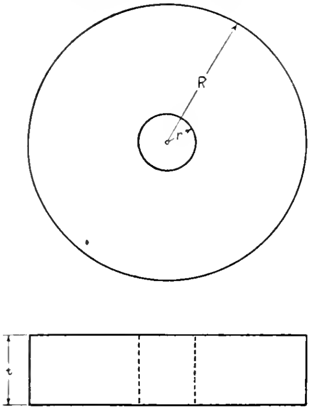

Fig. 1 Typical Head with Central Hole
(Any portion of head outside support circle not considered.)

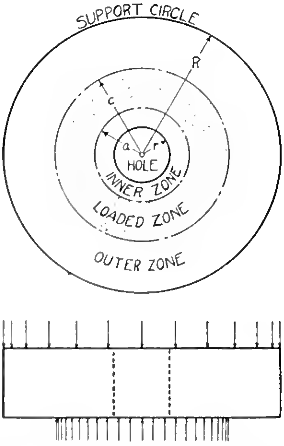

Fig. 2 Diagram of Typical Load
(Uniformly distributed over annular zone of radii *a* and *c*.)

d The loading is normal to the head, and may be so divided that each part is uniformly distributed over an annular zone. See Fig. 2. The three zones into which the head is divided by any such part of the loading will be called *inner zone, loaded zone* and *outer zone*. It is evident that this covers all cases of static fluid pressure in which the system is symmetrical with respect to all diameters. It covers also the case of a gasket load, for this may properly be regarded as uniformly distributed over a very narrow zone; in such a case, the width of the loaded zone is put equal to zero for the sake of convenience, although an absolute line contact is physically impossible. The same procedure as for a gasket load is applied, whenever there is a central hole, to a load concentrated around the edge of the hole, such as the force applied by an insert or plug. In any case where a load is treated as if concentrated on a circle, the loaded zone is considered not to exist. For the typical load, which is uniformly distributed over an annular zone, the total shearing force on any normal cylindrical section concentric with the zones (hereafter called circumferential section), having radius x, may be represented by $S = m + nx^2$, where m and n are constants pertaining to the zone cut by the section.

For the sake of convenience, the head will be regarded as horizontal. Although the loading may act partly upward and partly downward, the analysis contemplates only one part at a time, the joint effect of several loads being the aggregate of the several effects independently determined; it is therefore significant to distinguish between the opposite faces of the head as *tension face* and *compression face*, these terms having the same meaning as when applied to a simple beam.

Broadly considered, all loading is applied as normal external pressure, and causes an internal compressive force normal to the faces, throughout the loaded zone; the intensity of this force is equal to the intensity of applied pressure at the compression face, and decreases uniformly to zero at the tension face. If a load W be distributed over an annular zone of area $\pi(c^2 - a^2)$, the intensity of normal compressive force at the compression face is

$$q_n' = -\frac{W}{\pi(c^2 - a^2)}$$

the negative sign indicating compression. There are exceptions to this rule of surface application (for example, the dead weight of the head), but they are unimportant because any errors due to disregarding them are very minute in any actual case; if it be desired to take into account these exceptions, those terms in the resulting formulae which depend on the value of q_n' may simply be dropped.

NOTATION

The following notation is used throughout the paper:

R = radius of support circle. Positive. Unit = Distance

c = outer radius of loaded zone. Positive. Unit = Distance

a = inner radius of loaded zone. Positive. Unit = Distance

r = radius of central hole, if any. Positive. Unit = Distance

t = thickness of head. Positive. Unit = Distance

x = variable distance from center. Positive. Unit = Distance

y = variable deflection of neutral surface due to flexure alone. Positive. Unit = Distance

Y = variable deflection of neutral surface due to detrusion alone. Positive. Unit = Distance

z = variable vertical ordinate of a point in the head, measured from neutral surface. Positive if measured in some direction as load, negative if opposite. Unit = Distance

W = total load on loaded zone. Positive. Unit = Force

E = modulus of elasticity (Young's). Positive. Unit = $\frac{\text{Force}}{\text{Dist. squared}}$

λ = Poisson's Ratio. Positive. Pure Number

S = variable total vertical shearing force on a circumferential section. Positive. Unit = Force

s = variable intensity of vertical or horizontal shearing force in a vertical radial plane, at any point in the head. Positive. Unit = $\frac{\text{Force}}{\text{Dist. squared}}$

s_m = Value of s at any point in neutral surface.

The symbols for the intensities of internal stress and of internal force, other than shear, are given in the following table:

	Tension Face			Compression Face		
	Radial	Tangent	Normal	Radial	Tangent	Normal
Direct Stress..............	p_r	p_t	p_n	p'_r	p'_t	p'_n
Direct Force...............	q_r	q_t	q_n	q'_r	q'_t	q'_n

The quantities represented in this table are positive if tensile, negative if compressive. Their common unit is Force ÷ Distance squared. Direct stress intensity is defined as the rate of direct strain multiplied by E.

Although the deflections, which occur in the same direction as the load causing them, are considered positive, heed must be given

to the fact that separate loads, acting in opposite directions, cause opposite deflections. Both y and Y are considered zero at the support circle.

The neutral surface is everywhere midway between the two faces, but its distance from either face is slightly affected by diminution of the thickness t due to surface application of loading. However, this effect is so exceedingly small, that it will be considered in this analysis to be quite negligible. Therefore the deflection of either face, for any value of x, will be regarded as identical with the deflection of the neutral surface for that value of x. The fact that detrusive strains cause curvature of the normal elements does not invalidate this proposition. No proofs are given for the statements contained in this paragraph, for they are based on general theory and are not peculiar to the problem in hand.

EQUATIONS FOR FLEXURE AND DIRECT STRESS

Equations [1] through [15] provide means for determining flexure strains, direct internal forces and direct stresses at all points. Formulas for the constants of the integration are required and these are given for various physical conditions in Equations [16] through [45]. The derivation of these equations is given in the complete paper which may be procured from The American Society of Mechanical Engineers.

The shear deflections may be obtained from Equations [46] through [49].

Head with hole, load concentrated on circle of radius c:

Inner zone

$$A_1 = -\frac{2r^2}{1-\frac{r^2}{R^2}}\left[2\frac{1+\lambda}{1-\lambda}\log_e \frac{R}{c} + 1 - \frac{c^2}{R^2}\right] \qquad [40]$$

$$B_1 = C_1 R^2 - A_1 \log_e R - 2(R^2+c^2)\log_e \frac{R}{c} + 2(R^2-c^2) - \frac{2\lambda t^2}{3(1-\lambda^2)} \qquad [41]$$

$$C_1 = \frac{1}{1-\frac{r^2}{R^2}}\left[2\log_e \frac{R}{c} + \frac{1-\lambda}{1+\lambda}\left(1 - \frac{c^2}{R^2}\right)\right] \qquad [42]$$

Outer zone

$$A_3 = 2c^2 - \frac{2r^2}{1-\frac{r^2}{R^2}}\left[2\frac{1+\lambda}{1-\lambda}\log_e \frac{R}{c} + 1 - \frac{c^2}{R^2}\right] \qquad [43]$$

$$B_3 = C_3 R^2 - (A_3 + 2R^2)\log_e R \qquad [44]$$

$$C_3 = \frac{1}{1-\frac{r^2}{R^2}}\left[2\log_e R + 2 + \frac{1-\lambda}{1+\lambda}\left(1 - \frac{c^2}{R^2}\right) - \frac{2r^2}{R^2}(\log_e c + 1)\right] \qquad [45]$$

Inner zone $$Y = \frac{3(1+\lambda)W}{2\pi E t}\left[\log_e R - \frac{1}{c^2-a^2}(c^2 \log_e c - a^2 \log_e a) + \frac{1}{2}\right] \qquad [46]$$

Loaded zone $$Y = \frac{3(1+\lambda)W}{2\pi E t}\left[\log_e \frac{R}{x} - \frac{1}{c^2-a^2}\left(c^2 \log_e \frac{c}{x} - \frac{c^2-x^2}{2}\right)\right] \qquad [47]$$

Outer zone $$Y = \frac{3(1+\lambda)W}{2\pi E t}\log_e \frac{R}{x} \qquad [48]$$

Inasmuch as the distance between the neutral surface and either face remains constant for all values of x and for all conditions of loading (except for the exceedingly small reduction in this distance due to surface application of load, which has nothing to do with detrusion), the values of Y given by these equations apply to the shear deflections of both faces as well as of the neutral surface.

With respect to shear, it is not necessary to distinguish between a solid head and one having a central hole.

To handle the case of a load concentrated on a circle of radius c, let a approach c as a limit in Equation [46]:

Load concentrated on a circle of radius c:

Inner zone $$Y = \frac{3(1+\lambda)W}{2\pi Et}\log_e\frac{R}{c} \quad \ldots\ldots\ldots\ldots \quad [49]$$

Outer zone Use Eq. [48]

The treatment of shearing stresses and deflections is thus completed. The formulas are so simple, that it is not thought necessary to discuss their application to special cases.

Evidently the total or resultant deflection of the head at any point, is equal to the sum of the resultant flexure deflection y and the resultant shearing deflection Y at that point.

ILLUSTRATION

Two fairly typical cases have been analyzed for the purpose of illustrating the application of this article, and the results are shown diagrammatically in Figs. 3 and 4. The two cases are alike, except that the first is that of a solid head, whereas the second is that of a head having a central hole.

Each head is of steel 13 in. thick, and is simply supported on a circle 54 in. in diameter. The gasket is of appreciable width, but for convenience is considered to form a line contact along a circumference 42 in. in diameter. The total gasket load is 491,300 lb. Gas pressure is applied over the entire area of a circle 40 in. in diameter, this being the inside diameter of the gasket; the intensity of this pressure is 2000 lb. per sq. in. In the case of the head with the hole, the gas load acting on the stopper of the hole is transmitted to the head as a shear at the edge of the hole, which is 6 in. in diameter. The steel has a modulus of elasticity of 30,000,000 lb. per sq. in., and Poisson's ratio is taken as $^1/_3$.

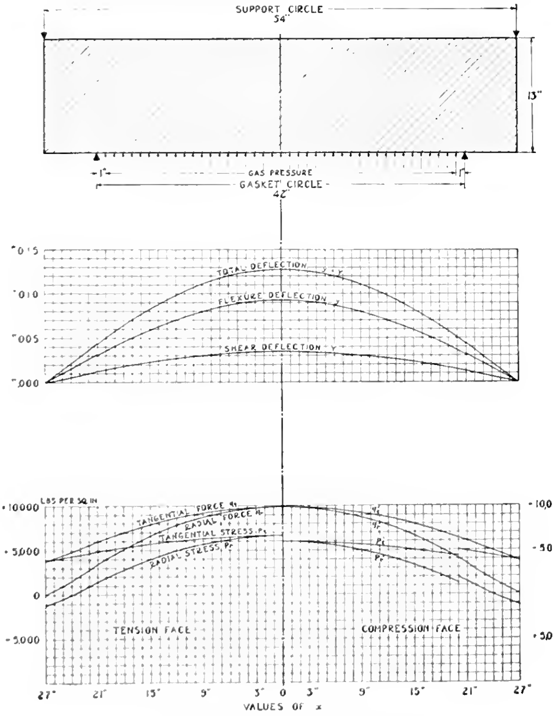

Fig. 3 Analysis of Solid Circular Head

The analysis of the solid head is made in two parts, one for the gas load of 2,513,300 lb., and the other for the gasket load of 491,300 lb. For the head with the hole there are three distinct loads: the main gas load, which is 2,456,700 lb. distributed over the annular space between hole and gasket; the gas load concentrated at the edge of the hole, amounting to the difference between 2,513,300 and 2,456,700 or 56,600 lb.; the gasket load of 491,300 lb.

We therefore take the following as the values for the given constants, which apply to all loads in both cases, i.e., solid head and head with a hole.

$R = 27$ in.	$E = 30{,}000{,}000$ lb. per sq. in.
$t = 13$ in.	$\lambda = {}^1/_3$

The following are the values of the other given constants, which are different for different parts of the analyses:

Solid Head	Head with Hole
Gas load—2 zones, loaded and outer $W = 2{,}513{,}300$ lb. $c = 20$ in. $a = r = 0$	Main gas load—2 zones, loaded and outer $W = 2{,}456{,}700$ lb. $c = 20$ in. $a = r = 3$ in.
	Gas load on stopper—outer zone only $W = 56{,}600$ lb. $c = a = r = 3$ in.
Gasket load—2 zones, inner and outer $W = 491{,}300$ lb. $c = a = 21$ in. $r = 0$	Gasket load—2 zones, inner and outer $W = 491{,}300$ lb. $c = a = 21$ in. $r = 3$ in.

The deflections, forces and stresses are determined separately for the several loads in each case, and the results are added to find the resultant effects. These results are plotted in Figs. 3 and 4. The break in the flexure deflection curve in each case is due to the assumed line application of gasket load, as explained in the analysis, and is numerically equal to 0.000067 in.

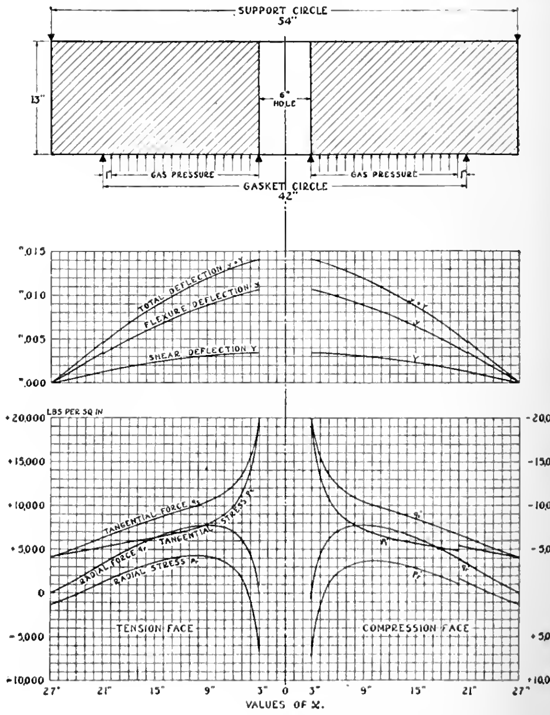

Fig. 4 Analysis of Circular Head Having a Central Hole

CHARTS

Figs. 5 to 12 facilitate the computation of critical stresses and deflections in cases commonly occurring, subject to the assumption of $^1/_3$ as the value of Poisson's ratio λ.[1]

Eight auxiliary quantities are introduced, *viz.* K_1, K_2, L_1, L_2, L'_1, L'_2, M_1, M_2. Each of these except M_2, is a function of r/R and c/R, r/R being zero in the case of a solid head; M_2 is a function of c/R alone. Each of the eight charts yields the value of one of these auxiliaries in any given case.

---

[1] For steel, $^1/_3$ is a convenient approximate value commonly employed; scarcity of experimental information in regard to lateral strainsmakes it useless to seek refinement in regard to the value of λ.

TABLE 1 AUXILIARY FORMULAS FOR USE WITH CHARTS, FIGS. 5 TO 12

		Solid Head (put $r/R = 0$)	
	Symbol	Due to load W distributed over area of circle, radius c	Due to load W concentrated on circumference, radius c
Intensity of stress in tension face at center	$p_t = p_r$	$\frac{W \cdot K_1}{3t^2}$	$\frac{W \cdot K_2}{3t^2}$
Intensity of stress in compression face at center	$p'_t = p'_r$	$-\frac{W}{3}\left(\frac{K_1}{t^2} - \frac{1}{\pi c^2}\right)$	$-\frac{W \cdot K_2}{3t^2}$
Center deflection due to flexure	y	$\frac{W}{Et}\left(\frac{R^2L_1}{t^2} - \frac{1}{6\pi}\right)$	$\frac{W}{Et}\left(\frac{R^2L_2}{t^2} - \frac{1}{6\pi}\right)$
Center deflection due to shear	Y	$\frac{WM_1}{E \cdot t}$	$\frac{WM_2}{Et}$
Deflection at radius c due to flexure	y	$\frac{WR^2L'_1}{Et^3}$	$\frac{W}{Et}\left(\frac{R^2L_2}{t^2} - \frac{1}{12\pi}\right)$
Deflection at radius c due to shear	Y	$\frac{WM_2}{Et}$	$\frac{WM_2}{Et}$
		Head with Central Hole of Radius r	
	Symbol	Due to load W distributed over area of circle, radius c	Due to load W concentrated on circumference, radius c
Intensity of tangential stress in tension face at edge of hole	p_t	$\frac{W \cdot K_1}{t^2}$	$\frac{W \cdot K_2}{t^2}$
Intensity of tangential stress in compression face, edge of hole	p'_t	$-W\left(\frac{K_1}{t^2} - \frac{1}{3\pi c^2}\right)$	$-\frac{W \cdot K_2}{t^2}$
Deflection at edge of hole due to flexure	y	$\frac{W}{Et}\left(\frac{R^2L_1}{t^2} - \frac{1 - r^2/c^2}{6\pi}\right)$	$\frac{W}{Et}\left(\frac{R^2L_2}{t^2} - \frac{1}{6\pi}\right)$
Deflection at edge of hole due to shear	Y	$\frac{WM_1}{Et}$	$\frac{W \cdot M_2}{Et}$
Deflection at radius c due to flexure	y	$\frac{WR^2L'_1}{Et^3}$	$\frac{W}{E \cdot 1}\left(\frac{R^2 \cdot L'_2}{t^2} - \frac{1}{12\pi}\right)$
Deflection at radius c due to shear	Y	$\frac{WM_2}{Et}$	$\frac{WM_2}{Et}$

The simple formulas classified in Table 1 give the stresses and the deflections at the center in the case of a solid head, or the tangential stresses and the deflections at the edge of the hole in the case of a centrally bored head, due to any load W uniformly distributed over the entire area of a circle of radius c concentric with the support circle, or due to any load W concentrated along the circumference of such a circle.

The formulas giving the effects of a distributed load, in the case of a head with a central hole, include the effects of that portion of the load which acts on the area of the hole and which is transmitted to the edge of the hole by the stopper which closes the hole; the proper value of use for W is the total pressure within the circle of radius c.

The formulas by means of which the auxiliary quantities were computed, are not reproduced here, being cumbersome; they were reduced directly from formulas derived in the earlier part of this article, with λ put equal to $1/3$. It is to be noted that these auxiliaries do not serve to give stresses and deflections *at all points*, as do the formulas of the analysis; they give only particular stresses and deflections of major importance.

The main practical purpose served by the charts is as follows. In the case of a steel cylinder head of uniform thickness t, simply supported around a circle of radius R, having a central hole of radius r (which is considered zero in case there is actually no such hole), sustaining a gasket load concentrated along a circumference of radius c, and sustaining also a static fluid pressure acting on the entire area enclosed by the gasket circle, *to find the maximum intensities of tensile and compressive stress, the maximum deflections due to flexure and shear, respectively, and the deflections at the gasket circle due to flexure and shear, respectively.*

DISCUSSION OF PAPER ON DEFORMATION OF CYLINDER HEADS

THE attendance at the General Session at which G. D. Fish presented his paper on stresses and deformation in flat circular cylinder heads was limited to a few particularly interested in this subject. The discussion took the form of a round-table talk in which the author answered the questions of this interested audience and explained further details of the problem presented in his paper. A résumé of the important points touched upon and bearing most directly upon the subject of the paper is given below.

W. H. Runkel[1] in opening the discussion asked what factor of safety was used in the flat cylinder heads designed for the nitrate plant. The author replied that a maximum intensity of direct stress of 10,000 lb. per sq. in. was allowed. The material was forged steel, and was expected to be a special alloy. Tests were being made at the Bureau of Standards, at the time the author severed his connection with the Bureau, to determine its strength, at high temperature, and the effect of a hole in it. Many specimens composed of carbon steel, nickel-carbon steel, chrome-vanadium steel, and molybdenum steel were being pulled at high temperatures. The ultimate strength of all the alloys was increased by elevating the temperature to 300 or 400 deg. fahr., but there was a tendency to decline beyond these values, which finally dropped off decidedly at more elevated temperatures.

Conrad C. Jacobson[2] asked if there was not a limit to the efficient thickness of the head, where a very high pressure was developed and there was a tendency toward bending between the bolt circle and the gasket circle. Would it not be a better design, he asked, to use hydraulic clamps directly through the gasket circle, rather than to depend on the bolt circle, and thus do away with this flexure?

The author answered that actual trials with screwed-in heads with the thrust directly against the gasket resulted in serious leakage.

Mr. Jacobson said that this was because no follow-up had been provided, and when the elasticity was gone there was a space between the head and the flange which decreased the initial tension on the gasket. He said that he was talking from experience, in work in which old-fashioned methods were used, but trouble was found in keeping tight joints. No matter how thick the heads were made, there was an initial pressure on the gasket with bolts.

The author said that his method was to calculate the deflation or bulging between the bolt circle and the gasket under a condition of bolt tension, without gas pressure, and also under the condition of bolt and gas pressure. If the overhang on the head beyond the gasket was properly proportioned to the other elements, there was a residual gasket pressure after the gas pressure was applied, and it was found feasible to do with a residual gasket pressure equal to about one-fifth of the total gas pressure. The elasticity of the plate made it possible to retain a residual gasket pressure after the gas pressure was applied.

Mr. Jacobson asked if it was always possible to determine the exact pressure that would be developed by the liquid pressure of the material handled.

The author answered that exact calculations were theoretically but not actually possible. The pressure in the system was maintained by means of a standard type of compressor, and the loss of head through the various members of the circulating system was quite definitely known, so that operating conditions were subject to fairly accurate control, both as to pressure in the apparatus and as to temperature.

In dealing with pressures inside any containers used for other purposes than the ones he was dealing with, he would expect that the calculated pressures would be subject to variations due to impurities of catalytic agents, and that certain mechanical and thermal conditions would affect the chemical equilibrium between the reagents and their product which could not be calculated exactly. Therefore, unless mechanical means were used for maintaining the system at a fixed pressure, a considerable percentage of variation in the pressure might be expected.

In connection with his problem there were incidental temperature differences to deal with, which meant that any construction of head or gasket which did not permit relative expansion laterally between the head and gasket seat would fail.

The bolting of the flanges seemed the most practical method for holding the gas, but even that was not very simple, because wrenches six feet long had to be used to turn up the bolts, and the ends of the wrenches had to be hit with sledges.

Mr. Jacobson, Thomas W. Milnor and the author discussed methods of fastening cylinder heads with clamps.

W. J. Drisko[1] said that he had been working on photoelectricity in connection with a number of problems of engineering interest, and the possibility of studying the distribution of stresses in a disk with a pneumatic pressure applied over the surface had occurred to him. He wondered if any information had been obtained through such means as this on the subject of the paper.

The author knew of no experimental evidence which would help Mr. Drisko. Strains, as put forth in his paper have been completely analyzed. The study of the inside of a thick plate, subject to flexure, showed that the normal elements which were straight before flexure, became curved after flexure, not due to that portion of the deflection which is called flexure but due to detrusion or shear. This was so slight that it would take a photomicrometer to detect it.

Elwyn E. Seelye[2] presented the following written discussion.

The method of analysis used by the author is based upon the elastic theory and is one of the most interesting examples of applied mathematics of which the writer is familiar. Where homogeneous material is in question, if the correct equations are written, very exact results may be looked for.

The writing and solving of these differential equations required considerable knowledge of higher mathematics.

It is interesting to examine the difference in results obtained by analyzing a cylinder head by ordinary statics as compared to the far more correct analysis based on the elastic theory.

In order to make the case as simple as possible, let us take the case of a circular plate uniformly loaded and simply supported around its perimeter, taking the moment about a diametrical section. The moment is readily obtained by determining the location of the center of gravity of the semicircle and the half perimeter, respectively. This gives us a total moment through the diametrical action of $\frac{w\gamma}{3\pi}$, which gives an average unit stress of $\frac{w}{\pi t^2}$, which if assumed to be parabolic in distribution gives a maximum stress at center of $\frac{1.5w}{\pi t^2}$ as compared with $\frac{0.83w}{\pi t^2}$ by the elastic formula.

This contrast in even greater if there is a small hole in the center of the head when the maximum stress is tangential and is three times that of a solid head, whereas the statical solution would increase the stress only directly with the material omitted.

These surprising differences are met with by engineers in floor-construction designs, particularly in the case of flat-slab construction, and affect the mechanical engineer in relation to the strength and economy of his plant-housing structures.

In the course of a paper read before the Institution of Engineers and Shipbuilders in Scotland. Mr. W. Rees Darling described a form of gear for marine propulsion. The place of the teeth on the pinion is taken by a bundle of loose wire rollers, which are free to move and adapt themselves to the form of the teeth on the gear wheel. Pinions of the new type may be moved into gear instantaneously or gradually while revolving at any speed. This is done regularly at present at a speed of 2000 revolutions per minute without shock or danger of any kind. The pinions in use so far have been fitted for the purpose of surmounting difficulties which had previously seemed insuperable, and have proved entirely successful.—*The Engineer*, Jan. 20, 1922.

A Discussion of Draft Tube Designs[1]

With Special Reference to Recent Forms Known as the Hydraucone Regainer and the Spreading Draft Tube

By WEBSTER K. RAMSEY,[2] BOSTON, MASS.

THE purpose of this paper is not to present the hydraulic draft tube from a highly theoretical standpoint, but rather from an angle which will be of interest to the greatest number at the present time. It will be surprising to any one who has studied the subject at all to find what a large number of operating hydraulic engineers have but a limited knowledge of either the importance of the draft tube or the action of the water in the different types.

The primary requisite for an understanding of the draft-tube effect upon the water is a knowledge of the action of the water as it issues from the runner of the turbine. In the explanation which follows, a vertical turbine is considered.

CONDITION OF WATER DISCHARGED FROM TURBINE RUNNER

The condition of the water discharged from a runner depends upon the specific speed of the runner With specific speeds up to 50, which designates a medium-head installation, the water is discharged in such a manner as to cause it to whirl in the same direction as the rotation of the runner, up to best gate. At best gate the water flows practically radially inward. Above best gate the whirl is in the opposite direction to the rotation of the runner. Considering values of specific speed above 50, which designates low-head installations, the velocity of whirl increases in magnitude as the specific speed increases. In this case the water does not change its direction of whirl even after best gate conditions are reached. It is particularly the low-head, high-specific-speed runners having high velocities of whirl which concern the draft-tube requirements, as will be shown later.

The following discussion, in order to cover every condition of whirl, considers a runner which

1 Below best gate gives a velocity of whirl in the same direction as the rotation of the runner; decreasing in magnitude as the gate opens
2 At best gate gives practically radially inward flow with no whirl; and
3 Above best gate gives a velocity of whirl in the opposite direction to the rotation of the runner, increasing in magnitude as the gate opens.

THE DRAFT TUBE

Turning now to the draft tube, it will be found that this device is used to permit the turbine being placed high enough above tailwater level to give accessibility. In providing an air-tight tube to conduct the water from the turbine runner to the tail race, it is hoped that a good part of the head lost because of the position of the turbine will be regained by the vacuum caused by the weight of the solid column of water flowing downward to the tail race. The problem, however, is not so simple. The water drops with a certain initial axial velocity even at best gate; off best gate there is added a velocity component of whirl. Water is discharged from a runner with a very high exit velocity, especially in the case of a low-head, high-specific-speed installation. This velocity represents a certain amount of static head acting on the wheel. If this discharged water is allowed to reach the tail race without giving up most of its velocity, then just so much energy will be lost.

The purpose of the draft tube, then, is to regain the axial component of velocity and the whirl component as well. In any case the regain, which is usually provided for by supplying a tube of increasing cross-sectional area which regains static head (H_s) from velocity head (H_v) in accordance with Bernoulli's theorem, will be practically impossible unless the water can be made to flow in parallel stream lines and without cross-currents or eddies. The nature of the installation in low-head plants has added one more requirement which demands that the discharged water be turned through an angle of 90 degrees in the shortest possible distance measured in the direction of flow. This latter requirement saves the costly excavation otherwise necessary.

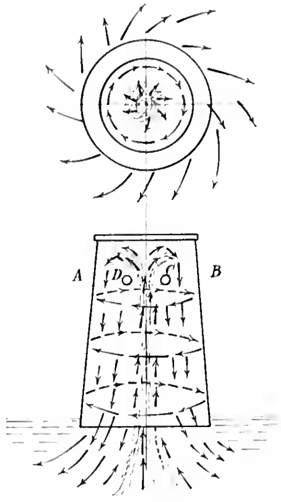

FIG. 1 SHORT, STRAIGHT DRAFT TUBE

THE PLAIN, SHORT STRAIGHT DRAFT TUBE

Consider a short, straight draft tube discharging into a tail race as shown in Fig. 1. When the turbine is operating below best gate, the water is discharged down the draft tube at an angle. Starting at 0.1 gate, and measuring the angle of flow with respect to the vertical axis of the tube, it is found that the angle of whirl near the sides of the tube is greatest at the lower gates, gradually decreasing until vertical (zero angle) at best gate. If the turbine mechanism is so arranged as to allow the gates to be opened much beyond best gate, the angle will be on the other side of the vertical, showing that the angle of whirl has been reversed, and instead of the water whirling in the same direction as the runner, it will whirl down in the opposite direction.

Now, when the water is whirling down a draft tube with great centrifugal force, the action causes water to be drawn up in the central part of the tube. See Fig. 1. This column ascends to a point directly beneath the runner, where it turns over and down and is discharged down the tube again with the water which is being discharged from the turbine.

The presence of this column of upward-flowing water is very undesirable in that it increases friction losses as well as reduces the static head or vacuum which would be formed and maintained directly below the runner.

It is important to note at this point that when the runner is discharging water at best gate, the water is flowing down in practically straight stream lines. Under this condition, there is no centrifugal action to cause the water to be drawn up from the tail race. There is, however, a loss due to sudden expansion at the discharge end of the tube.

It is also to be noted that in a tube of this type there is practically

---

[1] The present paper includes a part of a thesis submitted by Messrs. F. M. Rowell, R. A. Snow, M. H. Winchester and the author to the Massachusetts Institute of Technology in May, 1921, for the degree of Bachelor of Science, Parts I and II of which respectively dealt with an efficiency test of an Allis-Chalmers vertical hydraulic turbine, and a test of a White hydraucone draft tube. The apparent action of the water in the White regainer as tested led the author to investigate the action of the water in the light of the known conditions existing in other tubes.

It is to be noted that the thesis as submitted, which was practically the same as this paper with the exception of the more detailed description of the Moody spreading tube, was given to the Institute previous to the presentation of the paper on the White hydraucone regainer at the A.S.M.E. Spring Meeting in Chicago. The essence of the discussion following the presentation of the White paper as found in the July, 1921, issue of MECHANICAL ENGINEERING was contained in the above thesis as submitted in the middle of May, 1921.

The author wishes to acknowledge suggestions from Mr. W. M. White, received in an interview, regarding the construction of a pitot tube and method of testing the hydraucone regainer; and from Mr. L. F. Moody concerning the Moody spreading draft tube.

[2] Student, 1922, Mass. Inst. Tech.

Presented at the Student Session of the Annual Meeting of THE AMERICAN SOCIETY OF MECHANICAL ENGINEERS, New York, December 8, 1921. Slightly abridged. All papers are subject to revision.

no provision made for straightening out the water flow and thereby utilizing even the short length of tube which has an increasing cross-sectional area. Further, no provision is made for turning the water through 90 degrees, which is one of the chief requirements of a low-head installation.

Flaring Draft Tubes

Until the advent of the radial draft tubes the usual method of discharging water from a low-head turbine was to provide a flaring tube having a short 90-deg. bend as shown in Fig. 2.

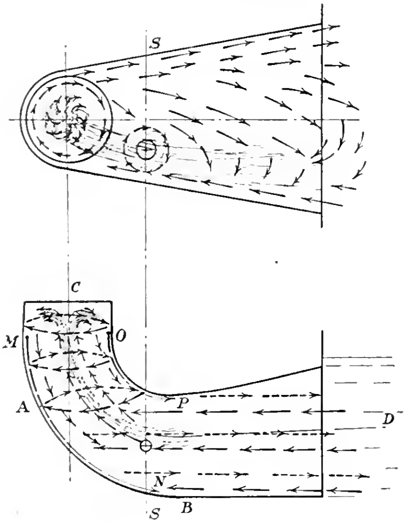

Fig. 2 Flaring Draft Tube with Short Body

If the turbine was operated always at best gate, it is easy to see that the direction of the water would be changed by friction along *AB*. Assuming that a full tube section of water started from *C* to *D*, it is to be noted that this water would pass points *M* and *O* with the same velocity. Assuming the runner discharges water at an equal rate over the entire area at *C*, it can be seen that as the water turns the 90-deg. bend the inner particles flowing along *OP* will not have the same velocity as those flowing along *MN*. Hence an eddy loss—a loss caused by cross-currents set up by the sliding of one layer of water over another—is present in this form of tube, even when operating at best gate. It has been further found that when straight stream-line conditions are obtained, the high-velocity water will flow along the bottom half of the horizontal portion of the tube and discharge below the point *D*. In not a few cases it has been found that when the upper portion of the flare was a little too high, the water actually flowed back into the tube above the line *D*.

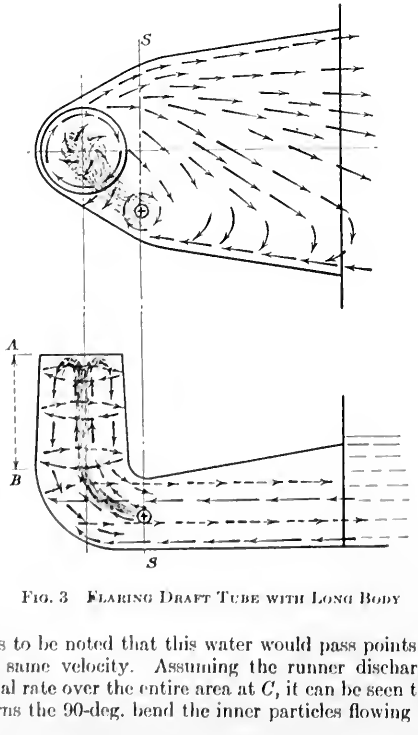

Fig. 3 Flaring Draft Tube with Long Body

Considering actual operation, a turbine is almost always enough off best gate to cause considerable whirling of the water. This whirling body of water possesses properties not unlike those of the rotating wheel of a gyroscope, and like a gyroscope it tends to keep in a plane perpendicular to its initial axis. Hence it will be seen that the water will not continue to rotate in a plane perpendicular to the central axis of the draft tube upon reaching the bend in the tube. This theory is substantiated by noting that the drawing action caused by the commotion of the water at the bend, as shown in Fig. 2, renders a part of the discharge area ineffective. In most cases the water actually flows back into the draft tube and is drawn from the points of most violent eddying (marked "+") up into the vertical portion as shown. In not a few cases the combined effect of the actions stated causes a complete loss of the total draft head available.

The construction of this type is not a factor in its favor. The best of these designs are made in concrete. When made of steel, the tube should bend smoothly at the elbow and not be made up of flat sections of steel plate.

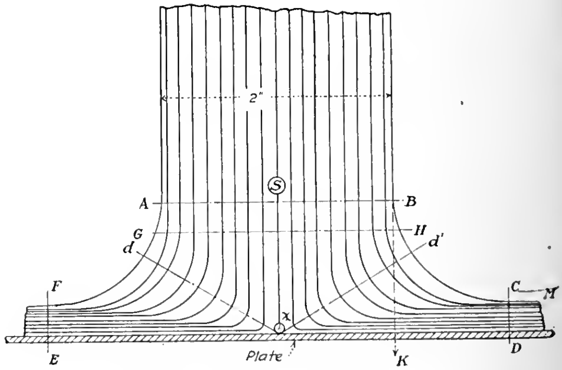

Fig. 4 Hydraucone and Hydraucone Action

Fig. 3 shows a draft tube similar to that of Fig. 2 with the exception of the longer body from *A* to *B*. This longer body has the effect of straightening the flow lines of the water, thus rendering it in a better condition for regaining through the diverging tube. It is evident that this design requires a greater distance from the horizontal center line of the turbine runner to the bottom of the tail race. The beneficial effect of the added length *AB* is actually very small.

The Hydraucone

Mr. W. M. White, manager and chief engineer of the hydraulic department of the Allis-Chalmers Manufacturing Company at Milwaukee, Wis., was the first to patent a means whereby static head could be regained from velocity head, and the direction of water be changed at the same time, in the shortest possible distance measured in the direction of the flow of water. These changes are brought about by what is called by the inventor the "hydraucone action" of the water, together with the regaining qualities of the design which act in accordance with Bernoulli's theorem.

The "hydraucone" is that portion of water bounded by the surfaces *AB* and *CD-EF*, Fig. 4, and its action, in the case of the straight jet normal to the plate, is to turn the water through ninety degrees without losing any velocity, and at the same time preserving parallel stream lines. The velocity head, moving vertically downward, is converted into static head, and this head used to reconvert

the static head into velocity head again, but in a horizontal direction with a very high efficiency.

THE WHITE HYDRAUCONE DRAFT TUBE

Realizing the importance of the hydraucone action of the water under the above conditions, Mr. White conceived the idea of utilizing the action to changing the direction of the water flowing from low-head turbines where expense of excavating for a long, straight draft tube would be prohibitive. The development of the White hydraucone draft tube is herein explained.

Referring to Fig. 4, a jet of water is shown impinging on a flat plate. The flat plate, which is the base of the hydraucone chamber, is made preferably circular and placed concentric with respect to the discharging jet.

Now, if the conoidal surface of the hydraucone, as *ABCF*, were enclosed in a closely fitting chamber, surface friction would result. Hence, a conoidal chamber is so constructed as to be slightly larger than the volume of a free hydraucone. At this point we have an enclosed hydraucone possessing all the characteristics of a free hydraucone. A step further is taken. In order to regain pressure from velocity it is necessary to provide a tube of increasing cross-sectional area. Therefore the conoidal chamber is not only made large enough for a free hydraucone with provision for friction, but also is slightly flared at the lower end, thus combining in one chamber the direction-changing action of the hydraucone with the pressure-regaining action of the section of increasing cross-sectional area.

The complete development of the design is shown in Fig. 5, a study of which will show how the pressure is regained in the following four distinct steps:

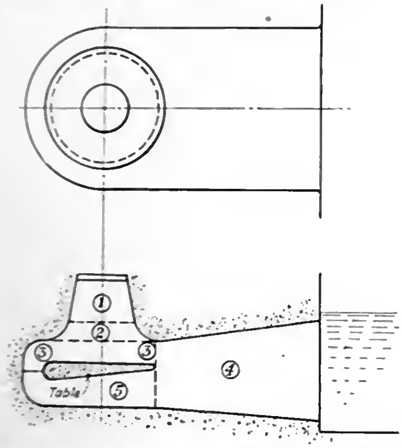

FIG. 5 WHITE HYDRAUCONE REGAINER AS PATENTED

1 First regain due to the diverging draft tube
2 Second regain due to the diverging hydraucone chamber
3 Third regain due to increasing area as water flows radially outward along the plate
4 Fourth regain due to the diverging draft tube which leads to the tail race
5 Collecting-chamber under the hydraucone baseplate. It serves as a place for collecting all the water coming off the plate and directing this water out through the section (4) into the tail race.

TEST ON THE WHITE HYDRAUCONE DRAFT TUBE

The discussion of the hydraucone up to this point has considered that the water issuing from the runner was moving in a radially inward direction and falling thence vertically down the draft tube. In actual practice, as before stated, this is seldom the condition. It is necessary, therefore, that we make a test to ascertain just what happens in a hydraucone-equipped draft tube when the water does not drop vertically downward like a jet, but comes whirling down at a sharp angle.

The draft tube on which this test was run was a part of an Allis-Chalmers 1875-kva. hydroelectric unit at Greggs Falls, N. H. The draft tube is equipped with a White hydraucone tube as shown in Fig. 6.

Ten tests were made in the following manner: The turbine was brought up to speed (257 r.p.m.), and by means of the load-limiting device on the back of the Allis-Chalmers governor, the gate was allowed to open to 0.1 gate. A special long pitot tube was then pushed into the draft tube until the tip was at the extreme opposite zone of the section. Both static-head and velocity-head hoses were connected to the U-tube of mercury. Knowing that the water was whirling down the draft tube at an angle, the exact position of the normal element of water was ascertained by turning the nozzle of the tube until the maximum velocity-head reading was obtained. At this position the velocity head and the angle of the nozzle were read. Holding the tube firmly, the velocity hose was disconnected and the static head read for that position. The tip was then drawn back into the next zone, of which there were ten, and readings taken in a similar manner. Having traversed the draft tube across the diameter at 0.1 gate, the turbine was brought up to 0.2 gate (speed constant throughout) and readings obtained in the same way as at 0.1 gate. In like manner readings were recorded for each tenth gate up to maximum gate opening (1.0).

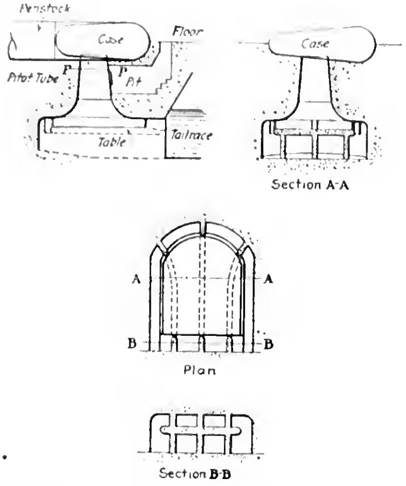

FIG. 6 WHITE HYDRAUCONE REGAINER AS INSTALLED AT GREGGS FALLS, N. H.

An inspection of the curves of Fig. 7 shows that negative velocity-head (H_v) and high static-head (H_s) readings were obtained in the central area of the draft tube at the lower gates, gradually diminishing in magnitude until at 0.9 and 1.0 gates all the velocity-head readings were positive and all the static-head readings were of not unusual magnitude.

The results show further that the angle the nozzle made with the vertical axis of the draft tube was greatest at the lower gates. It was also noticed that at the gates showing negative H_v readings the angle was greatest at the side of the draft tube and gradually decreased until, at the point of negative readings in the central area, the nozzle was vertical.

From the results of the readings taken by the use of a pitot tube traversed across the draft tube as previously explained, the following are noted:

a The velocity and angle of whirl of the water in the draft tube are greatest at low gates, decreasing as the gate is opened
b The negative velocities occur at the low gates when the angle of whirl of the water is greatest
c When negative velocity-head readings are obtained, the pitot-tube nozzle was vertical and in the central area of the draft tube
d The vacuum is greatest at lowest gate, decreasing as the gate is opened.

Recalling the conditions which produce the negative velocity-

head readings in the case of the short, straight draft tube, similar readings on this test appear to indicate that the column of upward-moving water is still present in this type of draft tube.

The construction of the hydraucone-chamber baseplate seems to indicate that it would be impossible for water to be sucked out of the tail race across the top of the plate and thence up the draft tube.

A more logical explanation as to the source of the upward-moving column of water is that water is picked up off the inner surface of the discharged water which is whirling down the draft tube as shown in Fig. 8. It is quite conceivable that the water is whirling around the circumference of the inner surface of the draft tube, leaving plenty of space in which the column of water could rise. At any rate there exists this upward-moving column of water in this design when the turbine is operating at the lower gates.

It is now necessary to consider whether the hydraucone action of the water is still present. In view of the foregoing paragraphs, the writer is inclined to doubt it when the turbine is operating off best gate and the water is whirling down the tube. The water now impinging on the plate is not a straight jet and therefore the action of a straight jet does not hold. With a straight jet, the force which builds up the static head at x, Fig. 4, is the inertia of the water falling vertically downward in a straight line all around that point. The force which prevents particle B, for instance, from continuing in a straight line vertically downward to K is the force which reacts at x and helps maintain the high static head at x.

Now the whirling water has the opposite tendency to the above, namely, a tendency to fly off at a tangent, out through the annular passage through area CD-EF, Fig. 4; or space (3), Fig. 5, and thus create a tendency to produce rather a vacuum at x than a pressure, or at any other point within the draft tube. From this it is evident that the hydraucone is probably not formed at any but the best gate.

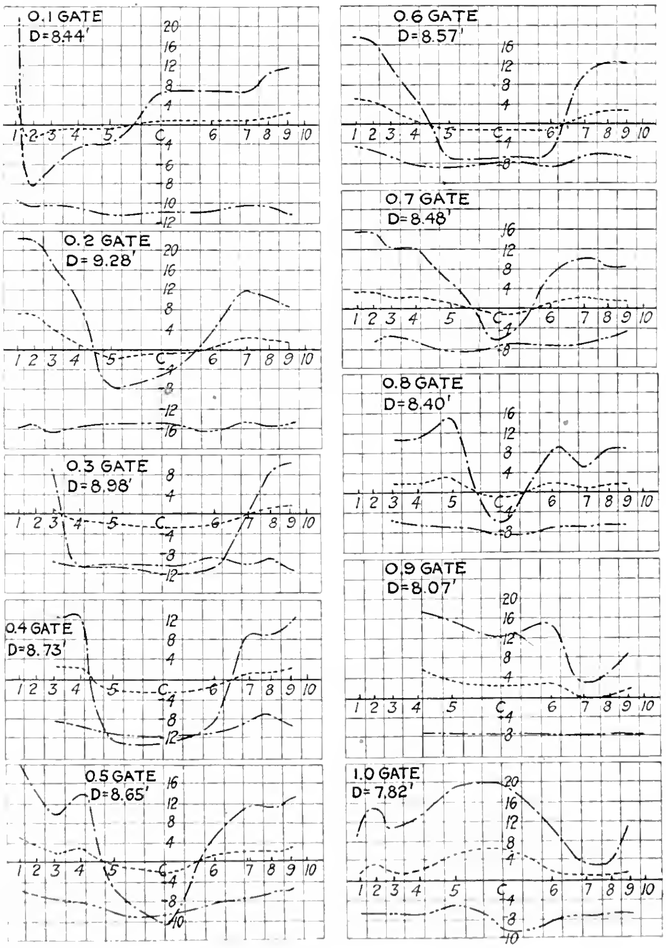

Fig. 7 Variation of Static Head and Velocity Head as Measured Across Draft-Tube Diameter for Different Gate Openings

_ _ _ _ _ _ _ _ Velocity of static head in feet of water
_ . _ . _ . _ . _ Static head in feet of water
_ . . _ . . _ . . Velocity (ft. per sec.) as calculated from velocity-head curve
D = distance from center line of pitot tube to tail-water level.

Notwithstanding the foregoing reasoning which seems to indicate that it would be impossible to maintain a hydraucone under whirling conditions of water, the makers state that they have made exhaustive investigations regarding this phase of the subject and have found that the hydraucone action is present under *any* condition of whirl, but that the pressure at the center of the plate may decrease to some extent, such decrease being dependent upon the velocity of whirl.

If we assume that the hydraucone action is not present at any but the best gate, it is necessary to explain just what are the advantages of this design. As far as the hydraucone is concerned, the writer is inclined to believe that there is very little advantage. There is, however, a gain which more than compensates for the loss of hydraucone effect and which is explained as follows:

In order to regain static head from velocity head efficiently, and regain the energy component of whirl, the filaments of water must be made to straighten out and flow in parallel stream lines. The results of the hydraucone draft-tube test show that the lower the gate opening the worse the eddying and the greater the angle of whirl; hence no material effect from either the hydraucone action or the increasing area can be expected from sections (1) and (2), Fig. 5. Yet it will be noted that at 0.1 gate and 0.2 gate the vacuum was very great. This is explained by recalling that water, like any mass, flies off at a tangent as soon as the restraining force causing it to rotate in a circle is released. Thus, when the whirling water reaches the annular opening (3) it rushes out through the passage with great velocity. The water is then flowing in straight stream lines and is in the proper condition for maximum regain of pressure head by means of the increasing area as the water moves radially outward along the plate, and finally through the diverging tube (4) into the tail race.

The water passing out through the annular space (3) has considerable energy due to the velocity with which it is thrown out. The shape of the annular passage is of increasing cross-sectional area not unlike that of a water ejector in action, and it is because of the suction caused by this ejector action that such high vacuum readings were obtained. That the foregoing action takes place is substantiated by noting that as the gate is opened the speed and angle of the water discharging down the draft tube decrease, as also does the vacuum, until at best gate (0.9) the vacuum is normal and the centrifugal action is replaced by the hydraucone action.

That the resulting loss of the hydraucone action is of less magnitude than the gain due to the ejector effect is proved by tests which show that the draft-tube efficiencies with this type of hydraucone-chamber construction increase as the gate is closed.

While the hydraucone action of the water was the cause for the particular design of Mr. White's, the writer believes that the design has won merit far more because of its ejector action than its hydraucone qualities, in so far as the hydraucone qualities have to do with a regain in the hydraucone chamber, especially under whirling conditions.

An interesting coincidence is to be noted with regard to the surging and other noises within the draft tube at different gates. In

connection with the pitot-tube traverses, the corresponding surging or rattling within the tube was noted for the different gates:

0.1 gate	Light surging as if made by small amount of water
0.2 gate	About same as 0.1 gate
0.3 gate	Surging 64 times per minute. Runner rattles
0.4 gate	Same as 0.3
0.5 gate	Surging partly ceased. Pitot tube vibrates
0.6 gate	Surging 72 times per min. Not so loud. No rattling of pitot tube
0.7 gate	Steady flow
0.8 gate	Steady flow
0.9 gate	Steady flow
Full gate	Steady flow.

It is interesting to note that the upward column of water begins to be very small at 0.7 gate. At this gate the surging ceases and steady flow is maintained.

Suggesting a cause for surging at lower gates, it may be said that the tube is not full of water. Then, if the turbine gates close a slight amount suddenly, the vacuum under the runner may lift the volume of water, which partially fills the tube, up toward the runner. The water, falling back again, may readily set up an oscillating movement which will continue until an equal force in the opposite direction happens to occur by the sudden partial closing of the gates as the surface of the oscillating volume of water is on the down "stroke."

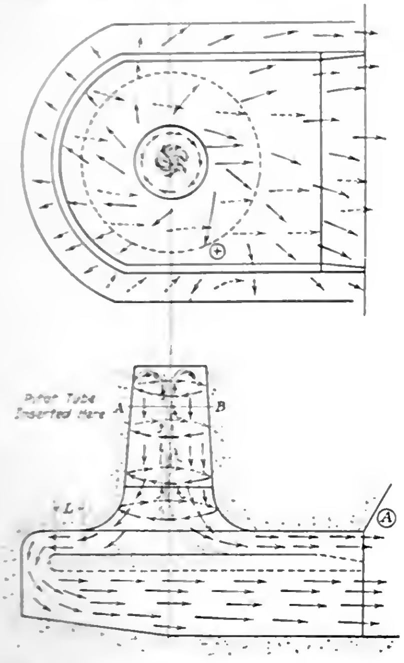

Fig. 8 Action of Water in the Greggs Falls Tube

Whatever the cause, it is certain that such surging is highly undesirable in that it causes an uneven pressure on the runner, thus imposing added duty on the governor and greater strains on the runner and penstock.

White Low-Head Hydraucone Regainer

Fig. 9 shows the White design for low-head installations. The base of the hydraucone chamber in this case is the bottom of the excavation, the collecting chamber being above the table top rather than below. This design may be used for extreme low-head installations. The space marked *s* on this plate corresponds to the space (3) in Fig. 5.

Horizontal turbines have been usually arranged to discharge the water into a sharp 90-deg. elbow placed at the top of a vertical draft tube. From what has been already said concerning the gyroscopic action of the whirling water, it may be readily seen that very poor draft-tube efficiencies are to be had with a sharp bend so close to the runner. The advantages of the hydraucone chamber draft tube on such horizontal turbines are obvious.

The Moody Spreading Draft Tube

Mr. L. F. Moody, consulting engineer of the I. P. Morris department of the Wm. Cramp & Sons Ship and Engine Building Company at Philadelphia, has designed a draft tube which, at first glance, bears a striking resemblance to the low-head design by Mr. White. See Figs. 9 and 10. The two designs appear to be practically identical, with the exception of the concrete cone in the Moody design. There is, however, a radical difference in the principles upon which the tubes are based.

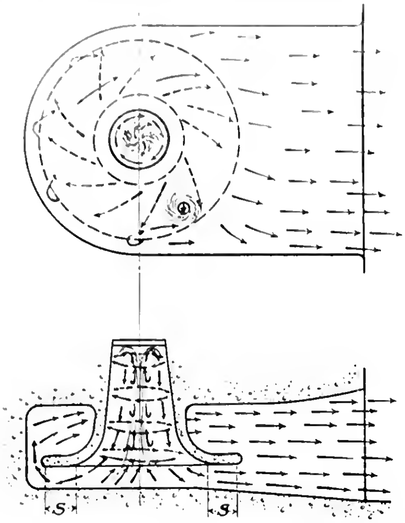

Fig. 9 White Low-Head Hydraucone Regainer

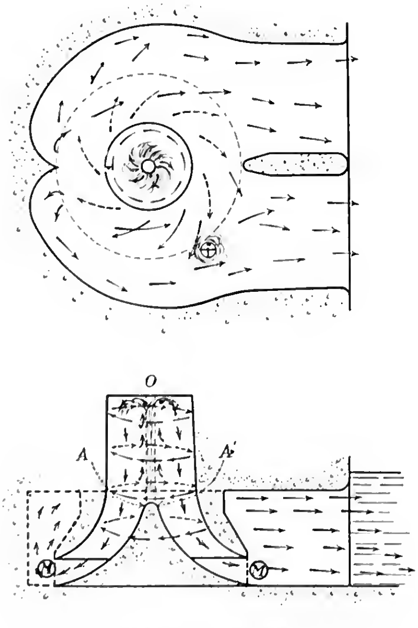

Fig. 10 The Moody Spreading Draft Tube

The Moody spreading draft tube is based on the principle illustrated by the familiar case of a free vortex in an open basin. Fig. 11 is a diagram of a cross-section through a free vortex. The water, as it whirls through the opening *OS*, assumes a definite shape

as shown by the solid lines *ABCDEFGH*. Mr. Moody has shown, with reference to the free flow of water through a space of revolution, that the velocity of whirl varies inversely as the radius and that the corresponding velocity head varies inversely as the square of the radius. If it is assumed, for instance, that the particle x is on the surface at A, it will increase its velocity of whirl as it approaches CD where the radius is smallest. The smaller the radius, the greater the velocity of whirl.

Since the reverse conditions hold—the greater the radius, the less the velocity of whirl—it occurred to Mr. Moody that if the water could be conducted even but a short distance away from the central axis of the draft tube without incurring eddy losses, the velocity of whirl of the water discharging from the runner could be effectively regained into static head. In other words, if the action of the free vortex could be reversed, the regain could be accomplished.

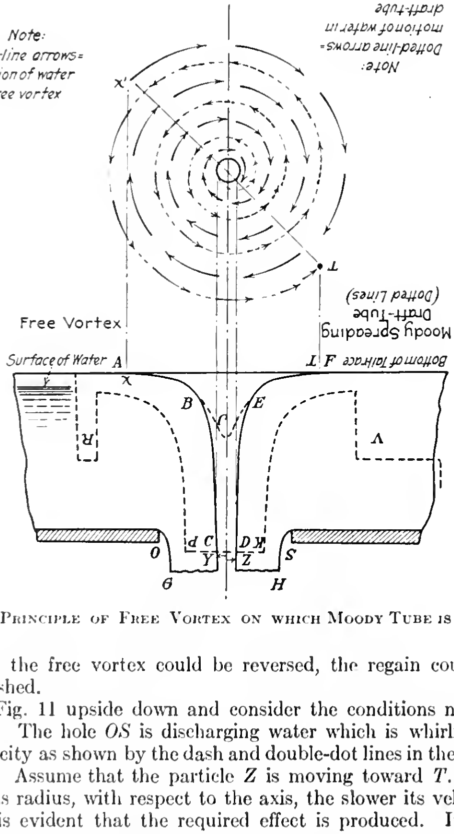

Fig. 11 Principle of Free Vortex on which Moody Tube is Based

Turn Fig. 11 upside down and consider the conditions now as reversed. The hole *OS* is discharging water which is whirling at high velocity as shown by the dash and double-dot lines in the lower drawing. Assume that the particle Z is moving toward T. The greater its radius, with respect to the axis, the slower its velocity. Thus it is evident that the required effect is produced. It now remains to suitably enclose the whirling water and conduct it far enough away from the axis to give the desired reduction in velocity.

The dotted lines in this figure represent an enclosed reversed vortex. The outline is that of the Moody spreading draft tube as installed at Niagara Falls. The concrete cone *TJX* does not fill the entire space which would occur in the case of a free vortex, because such a structure in a tube of this size would be unstable. However, it is recommended that the cone be carried up to the runner in all cases where practicable. The space *RV* is the collecting chamber into which the draft tube discharges.

Now if it is considered that a turbine runner is discharging water with a high velocity of whirl at *KP*, the water will flow spirally around the circumference of the tube, steadily decreasing its velocity as it increases its distance radially from the axis in accordance with the law previously explained. Thus the Moody spreading draft tube, based on the principle of the free vortex, regains static head from velocity of whirl as well as from velocity of discharge.

Conclusions

The extremely low-head installations which are now being considered have made it necessary to investigate thoroughly a method of regaining all the draft head possible. Since a low-head plant requires a runner of high specific speed, and therefore a high exit velocity from the runner, it is evident that the question of converting velocity head of the water revolving at high speed into static head is a question of great importance. Generally, when low-head plants are built, the expense of excavating for a long draft tube would be prohibitive; hence some form of radial draft tube is preferable.

The tests on the radial tubes as against the older designs prove conclusively that the radial type is a long step forward.

The writer suggests that an investigation as to the operation of both designs under service conditions be made before attempting a conclusion as to which of the two radial tubes is the better. It is further suggested that the investigation include some data as to the cost of construction of each form.

DISCUSSION

The discussion of Mr. Ramsey's paper was opened by Lewis F. Moody,[1] who complimented the author on his splendid paper upon which a very large amount of thought and study had been expended.

S. Logan Kerr,[2] showed a large number of slides, principally of spreading draft tubes, and including those at the 30,000-hp. plant at Muscle Shoals, Ala., the 37,000-hp. plant at Niagara Falls, and the 55,000-hp. unit of the Hydroelectric Power Commission. Mr. Ramsey had said that the Moody tube was particularly adaptable to low-head plants, but in one of the highest-head plants, 680 ft., a unit had recently been placed in operation and tested with the spreading tube with absolutely no vibration at any gate. In other words, the whirling component is prevented in the spreading tube, which is equally adaptable to the low-head or high-head plants.

H. Birchard Taylor[3] said that, relative to the subject of spreading tubes when used with high heads, it had been his experience that vibration was due to the condition in the penstock resulting in instantaneous action, and did not properly enter the question of efficiency.

Discussing Mr. Lyon's paper, which was presented after Mr. Ramsey's paper and which follows directly in this issue, R. L. Daugherty[4] said that results of tests he had made at Cornell University some four years previously agreed fairly well with those of Mr. Lyon. He had at that time tried the device of putting in a false floor in the bottom of the tail race so that it could be raised higher and higher and brought close to the mouth of the draft tube. When it was brought within $^5/_{16}$ in. and $1^1/_4$ in. from the end of the tube there was a persistent pressure instead of a suction. When the false floor was a distance from the end of the draft tube equal to a quarter of its diameter, the efficiency was a maximum.

DISCUSSION OF PAPER ON VERTICAL TRIPLE-EXPANSION PUMPING ENGINE

(*Continued from page 161*)

motor-driven centrifugal pumps had been operated in Indianapolis for over two years and that the efficiency, as determined by frequent tests, had not fallen off from the 86 per cent given when first installed.

As to first cost, the geared-turbine-driven centrifugal pump occupied but from $^1/_5$ to $^1/_6$ the cubical space of a triple-expansion engine of the same capacity. This made a very great difference in the cost of labor and material for building and foundations.

As to cost of upkeep, the first large gear-driven pump for water-works service was installed in Pittsburgh some ten years ago. It was still running, and there had never been any change in the gears or repairs made to the turbine.

As to the steady running of gears, none of the water-works gears had given any trouble, and there were something like 50 large units now in operation.

Flow in Conical Draft Tubes of Varying Angles

By GEORGE E. LYON,[1] TROY, N. Y.

THE purpose of this investigation was primarily to determine the velocity curves at several cross-sections of straight conical draft tubes. This is of importance as the results will show the flow and its variation along the tube. Incidentally the efficiencies of all but one of the tubes were found.

The function of the draft tube is twofold: first, to produce a suction under the turbine equal to the elevation of the turbine above tail water; second, to regain the kinetic energy of the water as it leaves the turbine. A plain cylindrical tube would meet the first requirement provided its mouth was submerged to exclude the air. It is of far greater importance, however, that the second requirement be fulfilled. The high-speed, high-capacity hydraulic turbine of today, operating under low head discharges water with as much as 25 to 30 per cent of the initial energy of the water in kinetic energy at discharge. Hence it may be seen that without an efficient draft tube the development of much of the potential water power under low head would be seriously handicapped. It is in the design of draft tubes operating under conditions mentioned above that the importance of this investigation may be realized; for, having found the character of flow, a tube may be designed to be more efficient in regaining kinetic energy. Heretofore nothing has been done in the way of finding the character of flow in diverging tubes.

For this thesis experiments were performed on seven draft tubes. All of the tubes were 3 in. in diameter at the throat, five enlarging to 6 in. at the mouth and two to 9 in.

One tube was of concrete, the others being made of heavy galvanized iron. The angle between opposite elements varied from 4 to 12 deg. Velocity traverses were made in each tube at four cross-sections, including the throat and mouth and at three rates of discharge. The efficiencies of all but one of the tubes were found.

This investigation was conducted in the hydraulic laboratory of the Russell Sage Laboratory, Rensselaer Polytechnic Institute Troy, N. Y., during the school year ending June, 1921.

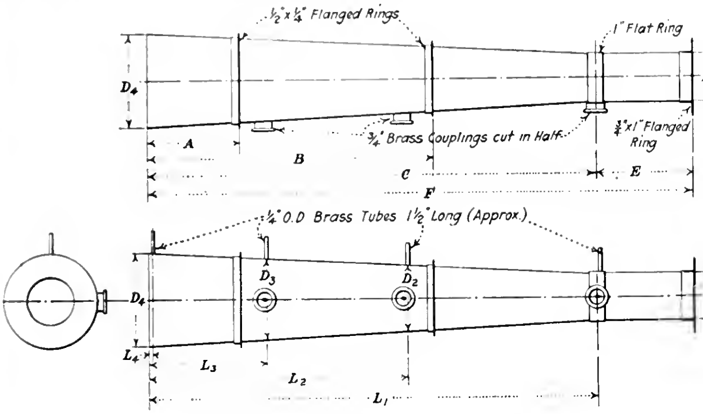
Water for the tests was pumped from a large cistern under the hydraulic laboratory by means of a 6-in. Lawrence double-suction centrifugal pump (1000 gal. per min.) direct-connected to an Allis-Chalmers d.c. motor. The water was pumped into a large tank overhead, from which it discharged through an 18-in. tee into a 5-in. pipe and thence into a 3-in. pipe through a 3-in. gate valve.

After discharging through the draft tube into the concrete-lined flume 30 in. wide by 18 in. deep and containing baffles for smoothing the flow, the water passed over a suppressed weir into the cistern below.

The first draft tube (A) was made of concrete, about one part cement to three parts sand. It was formed by pouring the concrete around a wood core in an 8-in. pipe 4 ft. long. The wood core was represented by a cylinder 3 in. in diameter by 5 in. long on the top of a truncated cone having a diameter of 3 in. at the top and 6 in. at the bottom in a length of 43 in. This gave an angle of 4 deg. between sides. This form of tube was very inconvenient, causing trouble in removing the core, also it was very heavy. The rest of the tubes, six in number, were made of galvanized iron and of the dimensions given in Fig. 1. Brass couplings ($^3/_4$-in.) were soldered to the draft tubes over openings large enough to pass the pitot tube through. These were spaced at equal intervals of cross-sectional area of the draft tubes. The upper section being at the throat and the lower one $^1/_4$ in. above the mouth. At these four sections piezometer connections were made of $^1/_4$ in. brass tubes soldered to the draft tubes and at 90 deg. from the pitot-tube connections. These tubes were connected so that the finish was perfectly flush with the inner surface of the draft tubes.

The Tests

Tests were made at three rates of discharge; 0.985, 0.745, and 0.476 sec-ft. The high rate for draft tube "*E*" was taken at 0.947 sec-ft. instead of 0.985 sec-ft. All tests were duplicated. Readings were taken at eleven (sometimes thirteen) points on each diameter. The points were taken closer together at the sides of the tube, spreading out toward the center. In the traverses taken at the throat sections, the throat pressure and tail-water gages were also read, just before taking the pitot-tube readings.



TUBE	ANGLE BETWEEN SIDES	A	B	C	E	F	D_1	D_2	D_3	D_4	L_1	L_2	L_3	L_4

Note: Material No. 26 Gal. Iron

Fig. 1 Dimensions of Draft Tubes Tested

Column 1 of the notes (Table 1) gives the radius from the center of the draft tube to the impact orifice of the pitot tube in inches. All readings between the two L's being taken on the left of the center line and those between the two R's on the right. Column 2 gives the piezometer readings in inches. In the next column are the pitot-tube readings in inches. These were omitted when the mercury manometer was used. Next are the differences in inches marked *y* or *h* for mercury or water, respectively. The next column gives the velocities in feet per second computed from *y* or *h*, and the last column gives the hook-gage readings in feet. The zero of the hook gage was 0.766 ft. and the readings for the rates of discharge were (see above) 1.112 ft., 0.961 ft., and 0.910 ft., respectively. For the high rate of draft tube "E" the reading was 1.000 ft. Whenever readings were taken at other rates of discharge, the velocity tabulated is that found by correcting the calculated velocity in the ratio of the discharge. The variation in discharge, however, was quite small. The notes taken at the throat sections contain two additional columns. One marked "Flume" gives the reading of the tail water in inches and the other marked "Piezometer" gives the throat piezometer reading in inches. The average difference of these two columns gives the negative pressure at the throat due to the regain of kinetic energy.

---

[1] Instructor, Dept. of Mechanics, Rensselaer Poly. Inst.

Abstract of a thesis submitted to the trustees and faculty of Rensselaer Polytechnic Institute in conformity with the requirements for the degree of Doctor of Engineering, June, 1921, and presented at the student Session of the Annual Meeting of THE AMERICAN SOCIETY OF MECHANICAL ENGINEERS, New York, December 8, 1921. All papers are subject to revision.

Computations

Reduction of mercury readings (y) for velocity:

$$v = c\sqrt{2g(13.6-1)y/12} = 1.007\sqrt{2 \times 32.2 \times 12.6\, y/12} = 8.276\sqrt{y}$$

for pitot tube No. 1.

Reduction of water readings (h) for velocity.

$$v = c\sqrt{2gh/12} = 1.007\sqrt{2 \times 32.2\, h/12} = 2.331\sqrt{h} \text{ (tube No. 1)}$$

$$v = c\sqrt{2gh/12} = 1.000\sqrt{2 \times 32.2\, h/12} = 2.316\sqrt{h} \text{ (tube No. 2)}$$

The following will serve to indicate in detail the computations, test D-1 (in Table 1) being selected.

From the piezometer reading of 54.20 in. on the mercury manometer by previous calibration the difference between the piezometer and pitot-tube readings is calculated to be 4.51 in. The zero reading for these two tubes is 51.90 in., but as the bore was not the same, a slight correction was introduced. $v = 8.276\sqrt{y} = 8.276\sqrt{4.51} = 17.58$ ft. per sec.

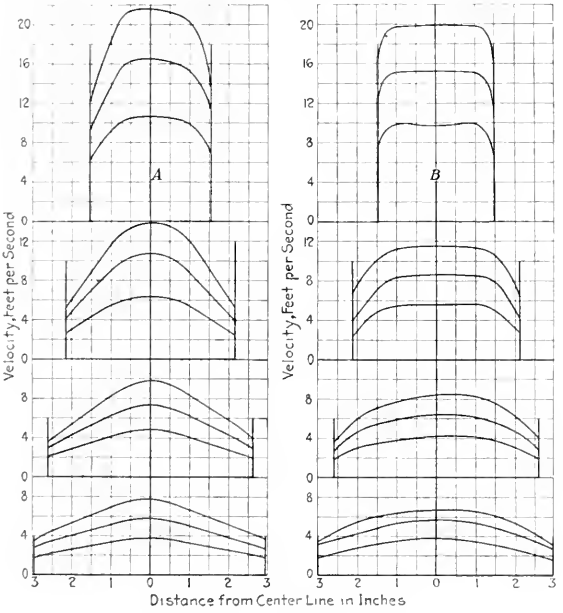

Fig. 2 Velocity Curves of Draft Tubes A and B

After plotting the velocity curves against radius, the moment of this area was found to check the discharge and the per cent error e tabulated in Tables 2 and 3. As will be explained later, the moment of the v-r curve is equal to $Q/2\pi$. $e = 100\,(Q - Q_0)/Q_0$, where Q is the discharge by integrating velocity curve and Q_0 is the discharge by weir which is taken as being correct. For tests D-1 and D-2, $e = 2.2$ per cent.

The average difference of the last two columns of tests D-1 and D-2 gives the negative pressure head in inches at the throat due to regain and is tabulated in Table 2 under "$-p$." In this case $-p = 60.96$ in. From the velocity curve plotted from these tests (Fig. 3) the kinetic-energy curve was constructed by plotting v^3 against r^2. The area under this curve is the kinetic energy possessed by the water at the throat section. In this case K.E./sec. = 394.0 ft. lb.

$$\text{The mean velocity head} = \frac{v^2}{2g} = \frac{\text{K.E.}}{\text{sec.}}\,\frac{1}{wQ_0}\,\frac{1}{(1+e)^3}$$

$$= \frac{394.0}{62.4 \times 0.985}\,\frac{1}{(1.022)^3} = 6.01 \text{ ft.}$$

$$\text{The efficiency of regain} = \frac{60.96}{12 \times 6.01} = 84.5 \text{ per cent.}$$

Values of $\frac{\text{K.E.}}{\text{sec.}}$, $\frac{V^2}{2g}$ and efficiency may be found in Table 2.

Consider test B-12 in which the hook gage regaging was 1.003 ft. instead of 1.002 ft.

1.42R	54.10	4.31	17.20	1.002	67.1	6.0	

The difference $h = 2.40$ in.

$$v = 2.316\sqrt{2.40} \times \frac{0.985}{0.990} = 3.58 \text{ ft. per sec.}$$

0.985 = discharge for hook-gage reading of 1.002 ft. (standard)

0.990 = discharge for hook-gage reading of 1.003 ft.

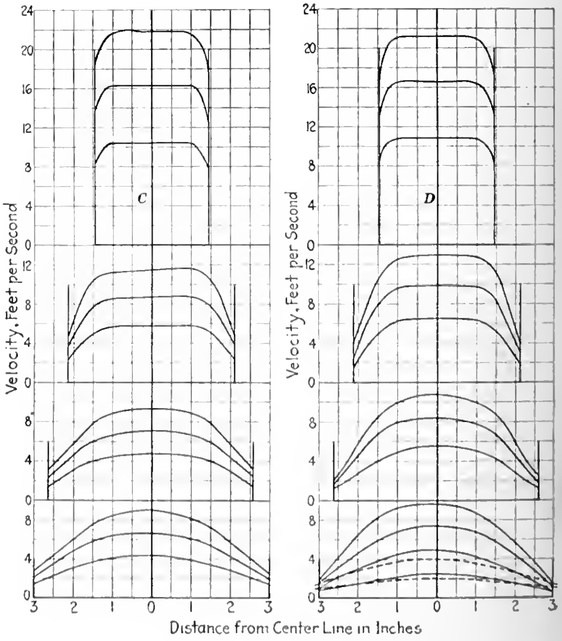

Fig. 3 Velocity Curves of Draft Tubes C and D

At this section the diameter on which the readings were taken did not equal the mean diameter. Hence upon integrating for discharge, the result was modified by multiplying by $\left(\frac{5.98}{6.00}\right)^2$ and the error (e) computed after this correction was made.

The various formulas which are mentioned above are derived as follows:

1 The moment of the area of a v-r curve about the center line is equal to the volume of water per second divided by 2π. Let r = radius in feet corresponding to the velocity in feet per second on

the v-r curve. Then Q = discharge in cubic feet per second

$$= \int_0^r v2\pi r dr = 2\pi \int_0^r rv dr.$$

But vdr is d (area) under curve, and $rvdr$ is the moment of this area about the center line. Performing the integration:

$Q = 2\pi \times$ moment of half-area about center line

$= \pi \times$ sum of the moments of the two half-areas about the center line.

2 The efficiency of a draft tube as a regainer of kinetic energy may be determined as follows:

Consider a draft tube as shown in Fig. 4, and that the upper tank

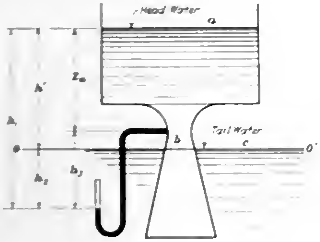

Fig. 4 Arrangement of Draft Tube

is raised or lowered until the head h' is sufficient to overcome the losses at a given rate of flow. Thus h' is the total loss. The velocity head in the upper tank is assumed to equal zero and there is no loss down to the throat of the draft tube. Then

$$p_a + z_a = p_b + \frac{V_b^2}{2g} \text{ or } \frac{V_b^2}{2g} = z_a - p_b + p_a.$$

Now

$$p_b = -h_2 + p_a \text{ and } p_a = 0 \therefore \frac{V_b^2}{2g} = h_1$$

Now h' represents the loss, so that the efficiency of a draft tube as a regainer of kinetic energy

$$= \frac{\frac{V_b^2}{2g} - h'}{\frac{V_b^2}{2g}} = \frac{-h_2}{h_1}$$

Readings are referred to atmospheric pressure as a datum. h_2 is negative as the zero of the gage board is at $O-O'$, the surface of tail water, and hence $\frac{-h_2}{V_b^2/2g}$ is positive.

Where there is a loss between a and b the efficiency can not be found by simply taking the readings h_1 and h_2. In this case the reading h_1 must be replaced by $V_b^2/2g$ determined from the velocity traverse taken at this section. This was the method used in this investigation.

Kinetic energy per second = K.E./sec. = $Wv^2/2g$

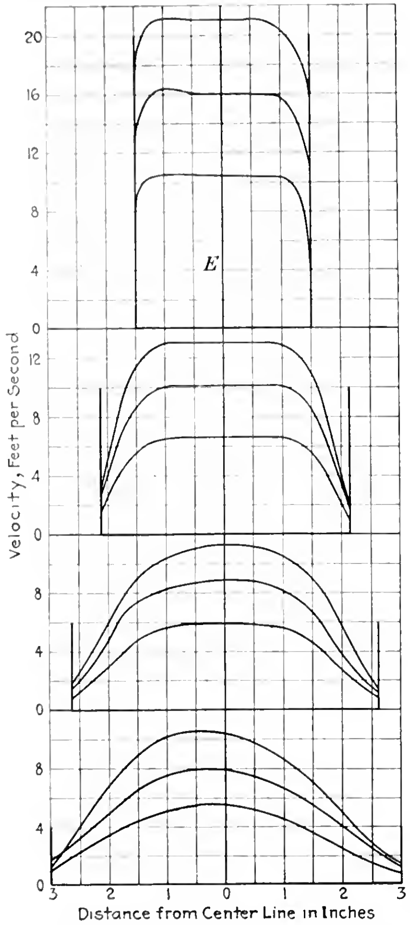

Fig. 5 Velocity Curves of Draft Tube E

$$W = \int_0^r wv2\pi r dr, \text{ where } w = \text{density of water}$$

$$\frac{\text{K.E.}}{\text{sec.}} = \int_0^r \frac{1}{2}\frac{v^2}{g}2w\pi rv dr = \frac{w}{2g}\int_0^r v^3 2r dr = \frac{w\pi}{2g}\int_0^r v^3 d(r^2)$$

Hence the area under the v^3r^2-curve multiplied by $\frac{w\pi}{2g}$ equals the kinetic energy.

To get $V_b^2/2g$, divide by W, since head is the amount of energy per pound of water.

$$\therefore \frac{V_b^2}{2g} = \frac{\text{K.E./sec.}}{W} = \frac{\text{K.E./sec.}}{wQ}$$

Due to the error e found by checking the velocity curves against the weir for discharge, a correction was applied to the velocity head $V_b^2/2g$ just found. This correction is based on the assumption that the velocities found from the pitot-tube traverse must be increased or decreased proportionally so that the discharge found by the "moment" method equals that found by the weir. It will be seen that this is equivalent to changing the constant for the pitot tube.

Let Q_0 = discharge by weir (assumed to be correct)

Q = discharge found by taking the moment of the v-r curve

$Q_0 = kQ$

$$\text{Error} = e = \frac{Q-Q_0}{Q_0} = \frac{1}{k} - 1$$

$$Q = AV \quad Q_0 = AV_0 \quad \therefore \frac{Q}{Q_0}\ \frac{V}{V_0}\ \frac{1}{k}$$

where v = pitot-tube velocity and v_0 = corrected velocity.

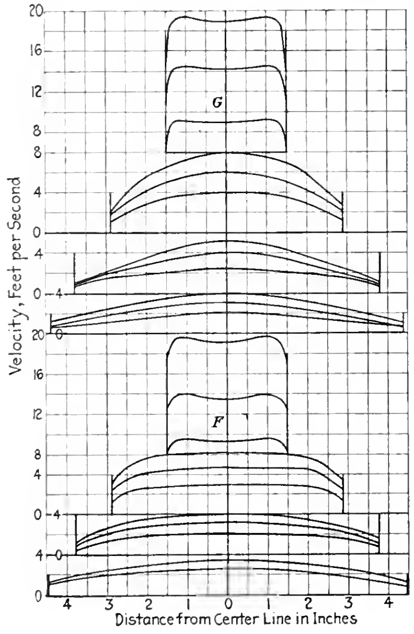

FIG. 6 VELOCITY CURVES OF DRAFT TUBES F AND G

Let K.E. = kinetic energy from v^3r^2-curve.

K.E. = theoretical kinetic energy from $v_0^3r^2$-curve (if such curve were plotted)

$$\text{As before K.E.} = \frac{1}{2}\int_0^r \frac{v^2}{g}\, 2w\pi rv\,dr$$

$$\text{K.E.}_0 = \frac{1}{2}\int_0^r \frac{v_0^2}{g}\, 2w\pi rv_0\,dr = \frac{1}{2}\int_0^r \frac{k^2v^2}{g}\, 2w\pi rkv\,dr$$

$$\therefore \quad \text{K.E.}_0 = k^3\text{K.E.}$$

and

$$\frac{v_0^2}{2g} = \frac{\text{K.E.}_0}{wQ_0} = \frac{k^3\,\text{K.E.}}{wQ_0} = \frac{\text{K.E.}}{wQ_0}\ \frac{1}{(1+e)^3}$$

since

$$k = \frac{1}{(1+e)}$$

Each velocity curve (Figs. 2, 3, 5 and 6) represents the results of two individual traverses or tests. Hence for the 86 curves shown, 172 tests were made. Two additional tests, D-25 and D-26, were made at the mouth of draft tube "D" at a discharge of 0.223 cu. ft. per sec. (hook gage = 1.851 ft.). This is the lowest full-line curve plotted under "D" (Fig. 3). Four more tests, D-27, D-28, D-29 and D-30, were made 6 in. below the mouth of draft tube "D;" the first two at 0.476 sec-ft. and the last two at 0.985 sec-ft. These two curves are shown by the dotted lines (Fig. 3). For the piezometer reading, the flume connection was used. The efficiency curves (Fig. 7) were plotted on a base of average velocity.

The velocity curves for the throat section of draft tube "A" were so distorted it was thought that a sudden enlargement to reduce the velocity would permit the water to be drawn off in a smoother stream-line flow. Accordingly the section of 8-in. pipe with bell mouth at bottom to meet the 3-in. section was introduced. The effect of this was very noticeable, as the curves for the remaining tubes were very nearly symmetrical.

With a couple of exceptions, the curves indicate:

1 That the velocity at the throat (before the water enters the flare) is uniform, falling off at the walls

2 That this uniform velocity breaks down at the sides of the diverging tube first and gradually falls off nearer and nearer the center. The curves for the first section below the throat indicate this

3 That some distance down in the draft tube, the uniform velocity which persisted at the center finally disappears and the velocity curve becomes peaked at the center.

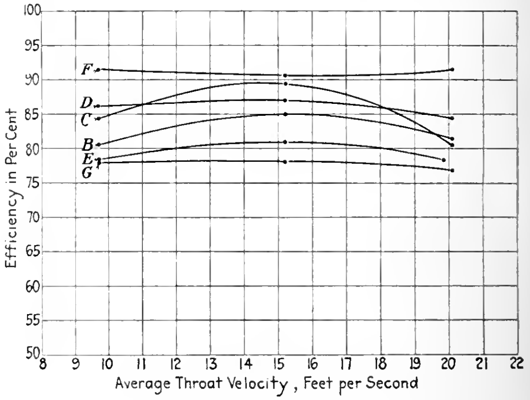

FIG. 7 EFFICIENCY CURVES OF DRAFT TUBES

4 That this peaked curve persists down the rest of the tube, flattening out somewhat toward the mouth, but even there having a center velocity of from twice to five times the wall velocity

5 That this ratio of center velocity to wall velocity increases with the angle of flare

6 That at a distance below the mouth of the draft tube equal to the diameter at this point, the curve remains peaked. This is only based on the four under water traverses below draft tube "D."

"Lateral flow," the motion of the water due to the flare, appears to be greatest near the wall, breaking down the velocity curve very greatly here. Its effect at the center of the tube is more gradual and, at first, uniform.

At the end of the tests the impact orifice in pitot tube No. 1 was plugged and a small hole drilled in the side. A traverse (Table 4) was made, referring the pitot-tube readings to the piezometer at the wall of the tube. It will be seen that the pitot tube records a lower reading than the piezometer. This is not due to whirl as the differences are all negative. The curvature of the pitot tube would not permit its side orifice to record true pressure.

TABLE 4 TRAVERSE DRAFT TUBE "D," 4.24-IN. SECTION

Rad. to pitot	Piezometer	Tube press.	Diff.	Hook gage
2.02L	42.75	42.30	−0.45	0.910
1.92	42.85	42.10	−0.75	0.910
1.72	43.15	41.70	−1.45	0.910
1.42	43.50	41.10	−2.40	0.910
0.82L	43.60	40.90	−2.70	0.910

0.82R	43.60	41.00	−2.60	0.910
1.42	43.40	41.40	−2.00	0.910
1.72	43.20	41.90	−1.30	0.910
1.92	43.00	42.30	−0.70	0.910
2.02R	42.85	42.60	−0.25	0.910

It would be of interest in the future to conduct tests under very low rates of discharge, also to determine whether or not there is a variation of pressure across a section.

Science in the Textile Industry

THE Textile Division of The American Society of Mechanical Engineers is endeavoring to direct the thought of the textile industry into scientific and engineering channels. In textile manufacturing, as in many other industries, there has heretofore been a great deal of empiricism. This has been notably the case in England where the industry has been built up on a great deal of tradition, and where very little fact has been used in many of the textile-manufacturing processes.

To the end of developing this kind of thought, the Textile Division held an important meeting in New York on the occasion of the Annual Meeting of the Society on Friday, December 9, 1921. The papers presented and the discussion which followed certainly confirmed the viewpoint that research work in the textile industry must be conducted on the basis that the engineering principles of every existing process must be suspected until research work has demonstrated that they are founded on fact.

British cotton manufacturers have just contributed $1,000,000 for the conduct of broad research work in the textile industry. This was brought out at the meeting by Charles T. Main of Boston, Past-President of the Society, who presented a report of the delegates of the Society to the Second World Cotton Conference at Manchester, England, in July, 1921. In the opinion of Mr. Main, this is a lesson for American manufacturers, who naturally pride themselves upon their openmindedness, and who will wish to keep abreast of their brothers across the sea.

The two technical papers presented at the session were Hidden Wastes in Textile Plants, by T. P. Gates, and Economy in Textile Drying, by B. R. Andrews. The first of these papers pointed out a few of the losses found in the average textile plant which have been largely overlooked, and which can be greatly reduced through the application of engineering research. The second enunciated the principles of satisfactory and economical drying, with reduced labor costs and minimum steam consumption. These papers are reprinted below.

Hidden Wastes in Textile Plants

BY THAYER P. GATES,[1] PROVIDENCE, R. I.

THE purpose of this paper is to point out a few of the losses found in the average textile plant which have been very largely overlooked and which can be greatly reduced through the application of engineering research. The types of losses considered are mainly those occurring in the operation of equipment and the utilization of materials. The paper also points out the opportunities in the textile field for men of engineering training.

The essentials in any study on the elimination of waste are:

a to determine the facts of present operation
b to determine what new facts may be found by analysis or research
c to apply these facts to the improvement of operation.

EXAMPLES OF METHODS EMPLOYED IN ELIMINATION OF WASTE IN TEXTILE MILLS

As an example of this method in the study of the operation of equipment, the output from a water mangle as used in cloth-finishing plants may be used. Knowing the present output of the machine, the first step would be to determine the maximum speed at which the machine would operate mechanically, allowing of course a proper factor of safety at the weakest point, and then find whether the goods could be put through the machine at that speed consistent with proper quality.

In such a study it may be found that the cloth will not open to width from the rope form at the required speed because the beaters on the scutcher will not take care of it properly. This involves experimental study by the engineer to determine changes necessary on this scutcher to take the increased output.

Then it may be found that the goods are damaged on the expander. The questions are immediately asked: at what place on the expander? what are the reasons for the damage? and how can the difficulty be eliminated? Another job for the engineer. Further, it may be found that the plaiter will not deliver the goods into the truck at the new speed. The engineer again asks why, and by proceeding to overcome this difficulty by employing the methods of engineering research to solve these problems, one at a time, the maximum capacity of the machine is finally reached. In many instances the output as a result of these studies is more than doubled, and the failure to take advantage of this possible increase constitutes a larger "hidden waste."

In many plants chemical problems may limit the output. As it is usually possible to redesign the mechanical equipment to take care of the maximum output from the chemical standpoint, the first research work should be done in the chemical laboratory. The problem is to determine what are the variables, and then to solve these variables for the best result of each when combined with each other. This involves the determination of a unit which must be applied in measuring and standardizing each variable.

For example, in the determination of luster on a mercerized fabric the standard unit should be saturation, which is measured by shrinkage of the cloth when submerged in caustic. In bleaching, the standard unit is the degree of whiteness combined with the strength and aging qualities of the goods bleached. The chemical research having been completed, the engineer must take these facts and apply them to the study of the equipment to give the maximum output.

The first experience of the author with textile research came when he was engineer of a large finishing plant. One of his problems was to locate a new bleach house to take care of approximately 50 per cent increase in production. A careful study failed to reveal any place where the building could be located and any continuity of the processes be maintained. The present bleach house was then examined to see if the increase could be handled there. The machinery was of modern type, was run at the highest practicable speeds, and could not be rearranged to provide for any additional equipment. An examination of the chemical part of the problem showed, however, that a 50 per cent increase could be taken care of with a slight increase in water and chemicals.

The problem was finally solved over protests that it had never been done before, by running two strands of cloth side by side through the same machinery at the same time instead of one as had been the previous practice. Many experiments were made before this was accomplished successfully, but the new method enabled the plant to secure approximately 50 per cent increase in production with practically the same equipment running at the same speed, with the same amount of labor and with a very slight addition of water and chemicals.

This solution caused a very considerable saving in the cost of production and also pointed the way to further investigations throughout the plant, with the result that many processes were revolutionized and large savings made.

A short time ago a mill treasurer spoke very contemptuously of the possibilities of engineering research in his plant, stating that he knew the business thoroughly, having started in it as a boy. When asked if he was not using individual "dollies" for scouring worsted cloth before dyeing, he replied that he had about twenty-five of them, each one of which required one operative. He was much surprised when informed that all of these dollies could be replaced by one continuous scouring machine, or at most two, re-

Presented at the Annual Meeting, New York, December 5 to 9, 1921, of THE AMERICAN SOCIETY OF MECHANICAL ENGINEERS. Slightly condensed. All papers are subject to revision.

quiring but one operative each and using a smaller amount of soap. Is this not a "hidden waste?"

The increase of output in the operation of tenter frames in another plant may be taken as a further illustration. After careful engineering investigation the dry or hot room was perfected and the frames readjusted to handle the capacity of the dry room. As a result the output was increased over 150 per cent, with a 50 per cent reduction in labor cost. The saving of labor on this job alone within a few weeks more than offset the entire cost of making the study and of changes on the machines.

The foregoing examples have all been taken from dyeing and finishing plants. Turning now to an entirely different line, a knitting mill started about eighteen months ago to study its machines to see if the output could be increased. The net result of much research work on these machines together with a study of the yarn used, was that the output of the entire plant was increased more than 25 per cent with the same equipment. The number of imperfections were reduced very materially, and in spite of the higher wage rate there was a substantial reduction in the labor cost per pound of product.

Various Methods of Cutting Down Waste

Occasionally in the study of equipment it is found that cutting down speed may increase output as well as quality. One illustration of this may be found on pickers in a cotton-spinning mill, where a reduction in the speed of the beaters frequently raises the quality of the product, cuts down waste of materials, and betters the production in the later processes.

Considerable saving can oftentimes be made in the purchasing of materials. This requires research to determine if a cheaper product may not be used to replace a more expensive one with equal or better results. An example of this is found in the studies made to determine if a lower-grade cotton may not be utilized to advantage. The use of this cotton calls for greater care in purchasing and a careful study of the processes of cleaning and mixing to maintain proper strength and uniformity. This, however, has been done by a number of mills without lowering the quality of their product and has resulted in large savings in the finished product.

Another source of loss in many plants is due to the waste of material in process and the reworking of materials which have become damaged. Records should be kept to show the extent of these losses as such records will undoubtedly assist in reducing the waste and act as a stimulant to maintain them at a minimum. In some finishing plants, for example, the amount of rehandled goods due to stains, poor dyeing, poor bleach, etc., oftentimes reaches 15 per cent of the work done, while in other plants it falls below 1 per cent. Frequently the amounts of seconds, remnants and rags reach large figures. In some plants no records are maintained of such losses, so undoubtedly these can be characterized as "hidden wastes."

In addition to the studies in the operation of the machines and in the utilization of materials, it is desirable to standardize thoroughly the labor jobs on these machines. Frequently the engineer can develop labor-saving devices that will reduce the number of operatives required. In other cases standardization may be carried to such an extent that less skill is needed on the part of the operatives and lower-grade labor can be used.

Throughout this paper emphasis has been placed on the savings which may be made by engineering research in the textile field, which has been much neglected up to this time, and it is the belief of the author that in the future great improvements in operation will undoubtedly result by the replacing of tradition with definite knowledge of facts determined by such research.

Economy in Textile Drying

By B. R. ANDREWS,[1] BOSTON, MASS.

THIS paper summarizes some of the means by which those expenses which contribute to the cost of textile drying may be reduced without causing simultaneous increases in damaged goods and without reduction in quality of work produced. There are many such items of expense, but they may be included under the three groups of labor, overhead, and steam.

The relative values of these groups are shown approximately in Fig. 1. The labor item includes only that labor actually applied to manufacture; the overhead item includes the labor for maintenance, as well as interest, depreciation, taxes, and the cost of power. While the relative value of each very naturally varies with the different classes of work, most textile drying is done either on cans or in an air drier, so that a fair average is obtained from a range consisting of starch mangles, drycans and tenters, and it was on such a range that the data for plotting Fig. 1 were obtained. Selection was made, not of an average installation, but of one operating with a comparatively high efficiency, thereby representing a good distribution of these expenses for low cost of drying.

It is natural to attempt drying economies by considering each item separately, yet it is no more possible to do so than in any other manufacturing process, for reduction in labor cost will probably be obtained by increase in investment and consequent overhead expense. If it is obtained by increasing the rate of drying, without much increase in investment, then a sacrifice of steam economy is likely to result. However, if the cost of handling is halved by halving the drying time, with a reasonable increase in overhead and no reduction (or even a 50 per cent increase) in steam consumption per pound of goods produced, an overall economy has resulted. Also, the increase of the rate of drying may make possible the combination into a range with calenders, starch mangles, etc., with a reduction of labor, not to one-half, but perhaps to one-third or one-fourth. Therefore, it is usually safe to assume that what is wanted above all else is to secure the maximum speed at which goods can be handled without damage, and then to maintain this speed at the minimum overhead expense and steam consumption.

While these conclusions are almost obvious, the actual drying process itself is not quite so clear, and a general understanding of it is necessary in order to consider this item of speed intelligently. Textile drying is usually nothing more than the conversion from liquid to gas of the free water, or free solution, carried by the material after leaving the extractor, suction box, or squeeze rolls. The hygroscopic moisture enters only rarely into the problem; that is, the process is really "drying," and not the processing often

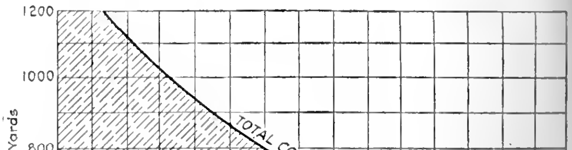

Fig. 1 Cost of Drying after Starching.—5-yd. Goods

Presented at the Annual Meeting, New York, December 5 to 9, 1921, of The American Society of Mechanical Engineers. All papers are subject to revision.

erroneously called "drying," which must be carried on under the most carefully regulated combinations of temperature, humidity and time. Consequently, with drier temperatures not exceeding 220 deg. fahr. and humidities approximating bone-dry atmosphere, we have simply a matching of vapor tension between the water in the material and the air in immediate contact with it. The higher the former, and the lower the latter, the more rapidly the process can be carried on.

There are three good ways of raising the vapor tension of the water in the material: (*a*) by contact with a hot surface; (*b*) by contact with hot air having a high wet-bulb temperature; and (*c*) by radiant heat.

There are two good ways of maintaining a low humidity in the air in immediate contact with the material: (*a*) by a high drier temperature; and (*b*) by rapid air circulation. The second is of the utmost importance because the film of air in immediate contact with the surface in an undisturbed atmosphere becomes very nearly saturated.

In the case of a material brought into contact with the hot surface, moisture may be transferred immediately into water vapor by maintaining the temperature of this surface high enough to keep the water in the material above 212 deg., the vapor then condensing and being reëvaporated by the surrounding atmosphere. It is just this method of drying that is utilized with drycans and drum slashers. It gives the most rapid rate of drying, as well as the greatest economy, particularly where an air current is used to disturb the sluggish film of saturated vapor on the surface of the material, thus giving a direct evaporation in addition. Such air circulation is best obtained by properly designed hoods over the slasher and blast nozzles on drycans.

In case of a material which cannot be brought into contact with the hot surface, but which must be dried quickly, rapid air currents become almost absolutely necessary and radiant heat desirable. However, the use of air currents and radiant heat is usually limited by the nature of the material and its possible arrangement in the drier, so that the most common form of textile drying, next to drycans and slashers, is that in which the material is heated and the latent heat of evaporation entirely supplied by the air in contact with it. For example, skein driers and festoon driers, with which the air is blown over or around the product, stock driers, and the "mast" type of knit-goods driers, with which the air is blown through the stock. However, there are cases in which strong air blasts and radiant heat can both be used, such as with a straight-away tenter frame. Here radiant heat alone, plus the convection, which is a natural result, will give one rate of drying; air blasting alone at a high temperature will give a higher rate; but a combination of the two, the highest rate.

From the foregoing it will be seen that textile drying resolves itself into two general classes: (*a*) with the material in contact with a hot surface; and (*b*) with the material in contact with air only, so that for a study of steam economy it is best that the two classes be considered separately; and the following table, prepared from the averages of many tests run on efficient drycans without air blast, gives the approximate distribution in per cent of the total steam used for the evaporation of one pound of water:

	Per Cent
Loss by radiation	20
Heating wet material	1
Evaporation of water	79
Total	100

or 1225 B.t.u. or $1^1/_4$ lb. steam at 5 lb. gage.

That drying on cans is a very efficient method is apparent and well known. However, actual mill averages often run double this consumption because of time lost between runs and improper proportion of width of goods to the width of cans.

In the second class of driers, possible economy of steam is much greater, for while the steam used per pound of water evaporated in a practical air drier can never be equal to that used in contact driers, the average air drier is more complicated and therefore more difficult to build and operate efficiently. The following table gives the destinations of heat required to evaporate one pound of water as calculated from test data on such a drier of more than average efficiency:

	Per Cent
Loss by radiation	14
Heating wet goods	0.5
Evaporation of water	46.5
Air change	39
Total	100

or 2150 B.t.u. or $2^1/_4$ lb. steam.

No loss has been attributed to leakage, because a properly designed drier can usually be so arranged that even though it may not be made air-tight, and openings must be provided for ingress and egress of the material, all of the leakage can be inward and become the new air required for evaporation without upsetting to any great degree the most efficient route of air travel through the drier.

Inasmuch as neither the heat required for evaporation, nor that necessary to raise the wet material to the temperature at which evaporation takes place, can be reduced to any material extent, steam economy must be effected by a reduction of radiation loss and the heat required to raise the temperature of the new air used to carry off the water vapor. It is sometimes possible to use the heat contained in this exhausted air either for heating or to augment some other drying process where a high percentage of humidity is permissible or desirable.

In the foregoing brief statement of generally well known drying facts, it has been the intention to bring out

1 The desirability of reducing the drying time in any drier at the expense of steam, or even labor, because of the preponderance of the overhead item
2 That this increase in the rate of drying must usually be obtained by increased temperature of the material being dried, and decreased vapor tension of the air actually in contact with it
3 That reduced labor costs, while usually a natural consequence of increased speed from the drier, can often be further reduced by combining the drier with other machinery into a range
4 That steam consumption can be cut only by eliminating leakage, reducing radiation by insulation, and using the minimum amount of new air for removal of water
5 Because cans meet all these conditions, they should be used in preference to all other types of driers wherever the nature of the product will permit.

DISCUSSION AT THE SESSION ON TEXTILE WASTE

AT THE session on Textile Waste, Past-President Charles T. Main, who had been appointed, with Sidney B. Payne, to represent the Society at the Second World Cotton Conference, held in June, 1921, in Manchester, England, submitted his report. Two papers were also read, namely, Hidden Wastes in Textile Plants, by Thayer P. Gates, and Economy in Textile Drying, by B. R. Andrews.

The discussion of the paper by Mr. Gates was opened by Clarence W. Marsh[1] who spoke of the possibilities of textile plants making some of the materials used by them. It is a fact, he said, that any concern using chlorine and caustic soda, especially a textile mill where steam is used for heating and power is therefore comparatively cheap, can make it infinitely cheaper than it can be bought. The reason, he said, is that many of the steps necessary to convert chlorine bleach into the finished product which the textile manufacturer uses represent economic waste. Chlorine and caustic soda can be used as delivered from the mill without conversion. To liquefy chlorine, he said, costs a cent and a half, the container from half a cent to a cent, and shipping a cent and a half. Money must be spent on the control apparatus for the liquid chlorine when an equal amount might purchase apparatus for making chlorine. And finally, the liquid chlorine must be transformed again into a gas.

Francis A. Chiffelle[2] said he wanted to emphasize the need of plant investigation. He asked if there was not a limit to the speed of tenters. A tenter chain, he said, was not built for high speed. Chain manufacturers would hesitate about putting in a chain like a tenter chain on ten-tooth sprockets and yet all tenter chain is run

on ten-tooth sprockets. With expensive chain like tenter chain there is a limit to the speed which should be allowed. Chain manufacturers, he said, figure on about 350 ft. or 116 yards per minute. The author said he had known tenter chains which had been running two years at a speed of 110 yards per minute, and occasionally at a maximum of 140 yards per minute. Mr. Chiffelle thought that this speed was too great for economy, and the author replied that the problem was to determine whether it was cheaper to run fast and have the chain wear out in a few years, or to run slow and have it last twenty.

D. M. Bates[3] spoke of his experience in replacing the iron bearings of chains with maple, and of work done by the late H. L. Gantt in doubling the yardage in textile plant with less wear and tear on the machinery. In regard to textile mills making their own bleach, as had been suggested by Mr. Marsh, he pointed out that this had been considered many times. The convenience of handling the liquid chlorine was appealing, even though the liquid was expensive. There were also difficulties, he said, in making chlorine in the relatively small quantities required by the average cotton bleachery.

H. M. Burke[4] said that as an engineer he realized that more scientific knowledge of the textile industry was needed. It was hard, he said, to convince owners of textile plants that this was so. Much of the knowledge of methods and machinery, however, was merely empirical. There was, he thought, a need for research in this field. It might be necessary to get enough publicity from engineers to sell such ideas to the man handling the money in a textile plant. This could not be done properly unless the processes were studied scientifically.

The author said that it had been his experience that it was easier to convince the man who handles the money than a board of directors. He had found it a good plan to tackle one problem at a time and to get results. Results were always pleasing to the board of directors.

Mr. Burke compared the textile with the shoe industry, in which highly specialized machinery had been introduced as a result of study.

Paul A. Marion[5] opened the discussion of Mr. Andrews' paper on Economy in Textile Drying. The author, he said, had pointed out very clearly that the way to increase economy in textile drying was to increase capacity. Several means of increasing capacity had occurred to him. The most important factor was the operator. Many existing installations would be capable of greater capacity if operators could be induced to obtain it. A second means was to improve the load factor in the case of multiple-width cans; to load these cans to the proper width with the number of strands for which they were designed. Why should finishing plants not be run twenty-four hours a day like paper mills? Another means of increasing capacity, he said, was to put all machinery in first-class condition, and another by removing the moist air from the cloth.

L. B. McMillan[6] discussed some statements by the author which had to do with loss of heat from galvanized iron surfaces. He pointed out that the tests made at the University of Illinois which showed that more heat was lost from such surfaces when covered with asbestos paper and to which the author referred, were correct, but he was afraid that a wrong interpretation might be placed upon the results because of the fact that the radiation from bright polished surfaces of galvanized iron or tin would increase as the surface became dulled by rust.

He also spoke of the insulating value of air spaces, pointing out that in order to be effective these spaces must be extremely small so as to prevent a circulation of air within them.

The author replied that he did not wish anything he had said to be taken as a complaint against asbestos insulation on the surfaces he had referred to. It was interesting to note, however, that these surfaces in connection with driers did stay bright.

J. A. Campbell[7] asked if double ends were still used on driers to take off the large amount of moisture that comes from nozzles on straightaway tenters. The author replied that he had not seen such installations in the last few years.

Charles H. Bigelow[8] asked what differences were found in applying air on the top and on the bottom of goods in straightaway tenters where a source of hot air is used. The author replied that such differences would depend upon the arrangement of the heater. It seems to make no difference if only air is used whether it is blown on the top or the bottom but with heater coils located above the goods there is always a danger of spots from dust and water dropping from above.

W. H. Carrier[9] said he wished to commend the author's consideration of the economic as well as the engineering features of drying. In the interest of accuracy he wished to clear up a possible ambiguity in the sixth paragraph of the author's paper where he states: "There are two ways of maintaining a low vapor pressure in the air in immediate contact with the material." All investigations show, he said, that the air in immediate contact with the material is saturated. The degree of saturation cannot be lowered. The saturated air can be removed, and by raising the temperature the moisture content of the air is raised. Heating has the effect of removing more moisture for the reason that the film of air near the surface of the material can absorb a greater amount of moisture for a given mass. The vapor pressure is increased, not decreased, and this involves a more rapid rate of drying. The object stated by the author is accomplished, but in the opposite way. A higher drier temperature does not decrease the vapor pressure of the air which is fixed by the air supply and depends on the dewpoint. It does raise the wet-bulb temperature and the vapor pressure of the moisture. The vapor pressure of the air in the film in contact with the material depends on the wet bulb-temperature. The rate of evaporation depends on the difference of vapor pressure of the film of air and the vapor pressure of the surrounding air. The vapor pressure of the film is above the vapor pressure of the air, and the higher temperature causes a high vapor-pressure difference. Rapid air circulation does not lower the vapor pressure on the material, except in the case of drycans and paper machines. The ambiguity lies in the fact that the type is not specified. If the author refers to drycans and paper machines, his statement is true and applies, but if air alone is used it does not apply, for in this case the vapor pressure of the air is not lowered, but remains practically constant and depends on the wet-bulb temperature. The effect of high velocity, however, is very important, as the author points out, because at high velocities the film of saturated air in contact with the material is swept away. For example, if the velocity is increased from that of still air to 230 ft. per min., the evaporation is doubled, and if to 280 ft. per minute, it is trebled.

De-Ironing Water

The water from the Metropolitan Water Board's wells at Waltham Abbey and Rammey Marsh having become charged with iron, it was decided to lay down a plant to deal with the trouble. The work is now nearing completion. The plant installed consists of twelve Candy iron-removing filters, each of 8 ft., 3 in. internal diameter and about 7 ft. high. The filtering medium consists of aerating and iron-removing sand and polarite. A small quantity of compressed air will be injected into the unfiltered water for the oxidazation of the iron in solution. The polarite acts as a catalytic agent, transferring the dissolved air to the iron with which it combines to form an insoluable hydrated oxide of iron. By this means it is hoped to reduce any iron which may be contained in the water to be treated to 0.01 part per 100,000. Ten of the filters, which will together be capable of treating two million gallons of the water in twenty-four hours, will usually be in service together, the remaining two acting as spares. For working the filters, a compressor plant, driven by Pelton wheels, has been installed. The whole of the apparatus is enclosed within a brick building, having a reinforced-concrete roof. The subsoil on which the building had to be erected is of a peaty nature, and is charged with water. It was consequently necessary to support the filters and the building on a reinforced-concrete foundation supported on reinforced-concrete piles.

Significance of Standardization to American Industry and the Federal Government

The Advantages of Standardization to All, Including the Government as the Largest Consumer—How the Government Should Coöperate with Industry—What is Being Done by the American Engineering Standards Committee

By A. A. STEVENSON,[1] PHILADELPHIA, PA.

THE significance and importance of standardization to industry and to the Federal Government seem almost axiomatic to those of us who have been actively interested in standardization work for a number of years, and since the present is a particularly opportune time for the launching of extensive coöperation between Government and industry, it seems well to point out the opportunities and means for such coöperation in industrial standardization.

The United States Government is probably the largest purchaser of materials in the world. The War and Navy Departments obviously have special requirements with reference to their military needs, but aside from these the interest of the Government in standardization is the same as that of all other consumers. The Government maintains an unrivaled group of research organizations, the principal object of which is the furthering of the development of our industries. In addition, the efforts of the present administration show a keen appreciation of the importance of standardization and its bearing upon industry as a whole, and constitute a most significant development in the relation of the Government and industry.

Of the many advantages to be derived by both industry and the Government from standardization along national lines, the most important seem to be:

1 Mass production, with its obvious advantage to the producer, means reduction in cost. Competition engendered by such production insures to the consumer, including the Government, the benefit of reduction in price.

2 Elimination of wide varieties and sizes permits producers to concentrate on those retained, and facilitates improvements in method and equipment that will ultimately result in the elimination of waste and the reduction of cost to the consumer, including the Government.

3 Putting all tenders on an easily comparable basis, promotes fairness in competition in both domestic and foreign trade, to the benefit of both producer and consumer.

4 Elimination of indecision in both production and utilization removes a prolific cause of inefficiency and waste.

5 Stabilization of production and employment means for the producer uninterrupted manufacture from stock during periods of depression. This is of vital interest to the Government as being of benefit to the country as a whole.

6 Accumulation of stock means prompt deliveries by the producer, and eliminates the necessity of the Government itself carrying a large inventory of material.

Again, the World War showed us the need of standardization along national lines, and the results obtained were of unlimited service to the country as a whole. Would it not be a calamity not to profit by the lessons taught by these experiences, adapting them to peace-time conditions? The advantages of national standardization are no less real in the midst of the post-war readjustment struggle. The need for unification of standards is, in fact, greater than ever before; for the manufacturer needs it to obtain maximum production, the distributor to minimize stock carried, and the consumer to secure articles at the least possible cost.

STANDARDIZATION AS A FACTOR IN TRADE

In outlining some of the factors tending to emphasize the significance of standardization, the great importance of standardization in helping to retain our foreign trade and meet keen competition from abroad has not been mentioned. In both Great Britain and Germany, national standardization is being carried on intensively. German industries are carrying out a far-reaching program of standardization as a necessary step in building up an unprecedented industrial structure which must rest in large measure on an extensive foreign trade. It is being woven very intimately into the industrial fabric of the country under the guidance of an organization which functions very much like the American Engineering Standards Committee, and in its work 5000 German industrial firms are coöperating.

COÖPERATION BETWEEN GOVERNMENT AND INDUSTRY IS VITAL

For reasons for which neither can be blamed exclusively, there is no doubt that the industries of this country and the Government Departments in many instances have not coöperated in a way to insure best results in standardization along national lines.

In national standardization the coöperation of the Government is necessary to industry and vice-versa. This result can best be realized through representative conferences in which specific projects are initiated, and representative committees by which the work on specific projects is carried out. In the work of such conferences and committees, industry and government should participate actively through accredited representatives of all interested bodies. It has been the experience of the American Engineering Standards Committee that the necessary industry-wide spirit of coöperation is developed and utilized through such representative conferences and committees. No doubt this statement would find confirmation in the experience of the Government Departments which have followed the same comprehensive plan.

To obtain the maximum of benefit from coöperation with industry, the Government should not attempt to set up standards at variance with standards acceptable for use by others for identical purposes. It should consider itself one (although a very large one) of the many consumers, and in its dealings with the manufacturers should coöperate with other consumers in formulating standards acceptable to both producer and consumer.

By means of conferences and committees truly representative of each industry as a whole (including consumers as well as producers), the bureaus can determine what are the needs of industry and learn in just what way their facilities can best be utilized. The bureaus need have no fear that their services will not be appreciated. The fact is that they will be recognized as being indispensable to the industries, and the industries will use their powerful influence to insure for the bureaus adequate equipment and personnel to carry on their work in a proper manner.

BENEFIT OF ONE SET OF STANDARDS FOR ALL

The benefit to be derived from having only one set of standards is so great that the producers should be willing to comply with more severe requirements that are uniform, in preference to less severe requirements different for each consumer or group of consumers. On the other hand, consumers should be willing to accept less severe requirements, thereby obtaining the benefit derived from economy in manufacture, rather than insisting on more severe requirements with accompanying added cost. An ideal specification is one which can readily be met by a producer who is competent and willing. When a specification is so severe that it condemns much good material, it results in economic waste. The creation of uniform national standards means economy for the producer, the consumer, and the country as a whole, and hence activities which will accomplish this desired result should be encouraged by the Government to the maximum extent.

---

[1] Chairman, 1921, American Engineering Standards Committee. Mem. Am.Soc.M.E.

Abstract of paper presented before the Washington, D. C. Section of THE AMERICAN SOCIETY OF MECHANICAL ENGINEERS, December 9, 1921.

A recent event of unusual importance was the organization of the Federal Specifications Board, for unifying the specifications for all Government purchases, military as well as non-military. This Board has been charged with the duty of compiling and adopting standard specifications for materials and services, and bringing specifications into harmony with the best commercial practice wherever conditions permit, in order to broaden the field of supply. If common standards are arrived at for the Government and the industries of the country, might it not be advantageous to have a common agency charged with the duty of determining what materials and services do meet properly the standards adopted? It is understood that in at least two of the most important industries of the country plans are now under consideration for the establishment of such a common bureau of inspection. As illustrating the possibilities of such a plan, may be mentioned the great services rendered both the industries and the Government by the adoption of uniform specifications for electric lamps, and the concentration of the inspection of all Government specifications for such lamps.

In discussing the relation of the Federal Government to the movement for industrial standardization along national lines, one naturally thinks first of the Government as a great consumer. But the relation is far broader than that, for in lending its moral and material support to the movement, the Government has an opportunity of the first importance in its labors to "promote the general welfare" of the country as a whole.

Relation of Government Research to Standardization

The relation of the great Federal research bureaus to industrial standardization is no less important than that of the great purchasing bureaus. Research and standardization are very closely related, and in many ways they are supplementary. By showing the need of reliable information as to the facts, in order to determine the best practice, and secure agreements on moot questions, standardization acts as a powerful stimulus to research and development. But what is of even greater importance, standardization is a principal means of getting the results of research and development work into actual use in the industries, so that the industries themselves, and finally the general public, may reap the advantages.

One of the most direct and effective methods of getting the results of the investigational work of the research bureaus introduced into, and of service to the industries, is by coöperation between the research bureaus and the industries, through working standardization committees, which must necessarily be joint committees of the various bodies interested in each specific project. The many advantages of such coöperation, both to the industries and to the bureaus, are obvious.

What is no less important, such coöperation is very effective in helping to extend a knowledge and appreciation of the work of the bureau in the associations speaking for the industry. As illustrating the significance of this, considerably more than a hundred national organizations are now coöperating through accredited representatives in the work of standardizing committees functioning under the auspices and rules of procedure of the American Engineering Standards Committee. In this work the Bureau of Standards, the Bureau of Mines, and the Forest Service are taking a very active part, and in so doing are rendering extremely important services to their respective industries. This coöperative work will be no less valuable to these bureaus than it is to industry.

Clearing House for Standardization Essential

In order that standardization along national lines may be brought about, it is necessary that there be some central body to act as a clearing house in standardization work. It is essential that there be brought together information concerning the organizations by which standards have been formulated and are being promulgated and details relating to such standards as are already in use. From the central body charged with the duty of collecting this information, it should be transmitted promptly wherever needed to insure the elimination of conflicts in the formulation of standards. The success to be expected from a central body organized for the purposes just stated obviously depends upon the authority invested in it, and the recognition received by it from the organizations throughout the country which are engaged in doing standardization work.

The need for closer coöperation in order to prevent duplication and the promulgation of conflicting standards in America crystallized in the appointment of a committee by the American Society of Civil Engineers, the American Institute of Mining and Metallurgical Engineers, The American Society of Mechanical Engineers, the American Institute of Electrical Engineers, and the American Society for Testing Materials, which formulated a plan resulting in the organization of a permanent committee made up of representatives of the five societies mentioned and the three Government Departments of War, Navy and Commerce. The Constitution of this committee, the American Engineering Standards Committee, was broadened later to permit the representation of other bodies, and at the present time it has 50 representatives from 18 bodies or groups of bodies including 7 national engineering societies, 13 national industrial associations, and 5 Government Departments, including the Departments of Agriculture and Interior in addition to the three already mentioned. There are now 37 different national organizations which have accepted sponsorship for a total of 59 projects. In addition there are 108 coöperating organizations other than the sponsor bodies, bringing the total to 145 national organizations who are actively coöperating in the work of the American Engineering Standards Committee and who have appointed accredited representatives to serve on sectional committees.

Objects of American Engineering Standards Committee

The objects of the American Engineering Standards Committee briefly stated are:

"To unify methods of arriving at engineering standards, and to secure coöperation between various interested organizations, in order to prevent duplication of work and promulgation of conflicting standards.

"To receive and pass upon recommendations for standards but not to initiate or develop the details of any particular standard.

"To act as an authoritative channel of coöperation in international engineering standardization.

"To promote in foreign countries the knowledge of recognized American Standards.

"To collect and classify data on standards and standardization bodies in the United States and foreign countries, and to act as a bureau of information regarding standardization."

As a result of the work in which the American Engineering Standards Committee is now actively engaged, existing conflicting standards are being brought into harmony, and there are being created truly representative committees to formulate new standards. The methods employed obviously differ somewhat from methods utilized hitherto, and it must be acknowledged that they are not yet fully understood by many of the organizations in America that should be coöperating in standardization along national lines.

The Rules of Procedure of the American Engineering Standards Committee are at times misunderstood, not by reason of their complexity but because of their extreme simplicity. Only when a standard has been formulated under such auspices that it has the endorsement of substantially the whole of the industry to which it applies is it considered qualified to be designated an "American Standard." The advantage resulting from insuring that all standards to be thus designated have been formulated under the proper auspices and are acceptable to the industry involved are so self-evident that it is sometimes difficult to understand why everyone does not appreciate the industrial significance of the work of the American Engineering Standards Committee. The Committee does not concern itself with the technical details of the standards submitted to it for approval, or formulated by committees organized under its auspices, but limits its investigations to a study of the procedure followed in developing the standard with particular reference to the representative character of the group of persons by which the standard has been formulated and the organizations by which it has been adopted or approved.

The decision of the American Engineering Standards Committee

(Continued on page 203)

SURVEY OF ENGINEERING PROGRESS

A Review of Attainment in Mechanical Engineering and Related Fields

Thermodynamic Bases for Determining Efficiency to be Expected from Gas Turbines

By H. SCHMOLKE

TESTS resumed since 1918 with 8000-hp. Holzwarth gas turbines justify the expectation that the difficulties of applying gas turbines for driving turbo-dynamos are not insuperable. The internal-combustion engine may in the not distant future reach a stage of development to a position to compete with the prime movers now employed in electric central stations. In fact, the German State Railroad Administration has already placed orders for several Holzwarth turbines of considerable capacity, and the experience of operating them ought to aid in their further development.

Whether the final aim will ever be attained, depends of course in the first instance on the efficiency to be attained in this type of apparatus. If for one reason or another it is basically impossible to attain a degree of efficiency that will place the gas turbine on a par with other types of heat engines, obviously all the efforts of Holzwarth and other investigators in the field are doomed to failure. Hence it is of the greatest importance to determine in advance the maximum efficiency to be expected from a projected installation, and the following represents a kind of synopsis of investigations published within the last 10 years by prominent experts in thermodynamics. In this connection the gas-entropy chart is of paramount importance. Such a chart may be obtained by plotting curves of equal pressures and equal volumes, with ordinates representing the absolute temperature T and abscissæ the entropy S. The curves themselves may be derived by the following process of calculation.

It is a well-known fact that the heat supplied during the process is equal to

$$dQ = TdS = c_v dT + Apdv$$

when c_v is the specific heat at constant volume, A the heat equivalent, p the specific pressure and v the volume. From this it follows that

$$dS = c_v \frac{dT}{T} + Ap\frac{dv}{T}$$

It is, however, possible to write

$$T = \frac{p_v}{R}$$

in accordance with the equation of state, provided R is a gas constant. If this relation be introduced into the second term of the right-hand side of the equation, we obtain

$$dS = c_v \frac{dT}{T} + AR\frac{dv}{v}$$

and this after integration between the initial values of T_0, v_0 and the final values T, and v gives

$$S - S_0 = c_v \log \frac{T}{T_0} + AR \log \frac{v}{v_0}$$

or, with common logarithms,

$$S - S_0 = 2.303 \left(c_v \log \frac{T}{T_0} + AR \log \frac{v}{v_0}\right)$$

There are, however, the two well-known thermodynamic equations:

$$p_v = RT \text{ and } c_p = c_v + AR$$

from which and the preceding equation, it follows that

$$S - S_0 = 2.303 \left(c_p \log \frac{v}{v_0} + c_v \log \frac{p}{p_0}\right)$$

but at constant pressure $p = p_0$ and $\log \frac{p}{p_0} = 0$.

This gives for the desired curve of pressure the formula

$$S - S_0 = 2.303\ c_p \log \frac{v}{v_0}$$

Since, further, in accordance with the equation of state with pressure p constant, T/T_0 is v/v_0, one easily obtains for the curve the very convenient expression $S - S_0 = 2.303\ c_p \log \frac{T}{T_0}$. If, on the other hand, it is the volume that is constant, that is, $v = v_0$ and $\log \frac{v}{v_0} = 0$, we obtain in a similar manner the expression $S - S_0 = 2.303\ c_v \log \frac{p}{p_0}$, and as at constant volume one may write $p/p_0 = T/T_0$, the above equation may be written as

$$S - S_0 = 2.303\ c_v \log \frac{T}{T_0}$$

Now if the entropy of a gas at 0 deg. and any pressure p_0 as well as volume v_0 be stated as being equal to 0, it becomes possible to plot either the pressure or volume curve on the T-S diagram. In order, however, to plot the curve of pressures for a higher pressure, it is necessary to determine its origin on the ordinates. To do this, it is necessary to compute the temperature in adiabatic pressure from p_0 to np_0, where n may be any number. According to the equation of state

$$\frac{T_2}{T_1} = \frac{p_2 v_2}{p_1 v_1}$$

and further in adiabatic compression

$$p_1 v_1^{\kappa} = p_2 v_2^{\kappa} \text{ or } \frac{p_2}{p_1} = \left(\frac{v_1}{v_2}\right)^{\kappa}$$

By combining this equation with the preceding one, we find

$$\frac{T_2}{T_1} = \left(\frac{v_1}{v_2}\right)^{\kappa - 1}$$

and furthermore, since according to the adiabatic equation

$$\frac{v_2}{v_1} = \left(\frac{p_1}{p_2}\right)^{\frac{1}{\kappa}}$$

we find that

$$\frac{T_2}{T_1} = \left(\frac{p_2}{p_1}\right)^{\frac{\kappa - 1}{\kappa}}$$

If we write now $p_1 = p_0$ and $p_2 = np_0$, we arrive at equation

$$\frac{T_n}{T_0} = \left(\frac{np}{p_0}\right)^{\frac{\kappa - 1}{\kappa}} = n^{\frac{\kappa - 1}{\kappa}}$$

This equation determines also the origin of the line of pressures for the compression n times as great. Where the curve of volumes in adiabatic compression begins at the nth part of the original volume, the equation

$$\frac{T_2}{T_1} = \frac{T_n}{T_0} = \left(\frac{v_0}{\frac{1}{n} v_0}\right)^{\kappa - 1} = n_{\kappa}^{-1}$$

holds good. With these two equations available there is nothing further needed in laying out the entropy charts.

Prof. A. Stodola, of Zurich, Switzerland, was probably the first to plot such curves. In the fourth edition of his work on Steam Turbines he published a temperature-entropy diagram for gases, diagrammatically reproduced on the right-hand side of Fig. 1. In developing the arithmetical foundations for the computation of these curves, the specific heat at constant volume c_v of the gases under consideration was referred to the mol, which was indicated by the use of a modified script. It was assumed that $c_v = a + bT$, where $a = 4.67$, and b is a constant depending on the properties of a given gas. It was expected that in this way the variation of heat capacity with temperature would be sufficiently taken care of. Under this assumption it would be found from the above equation

$$dS = c_v \frac{dT}{T} + AR\frac{dv}{v}$$

that

$$d\mathfrak{S} = a\frac{dT}{T} + b\,dT + A\mathfrak{R}\frac{d\mathfrak{B}}{\mathfrak{B}}$$

the bold-face letters indicating that the quantities are computed on the mol basis. From this, by integration between definite limits, it is found that

$$\mathfrak{S} - \mathfrak{S}_0 = a \log \frac{T}{T_0} + b\,(T - T_0) + A\mathfrak{R} \log \frac{\mathfrak{B}}{\mathfrak{B}_0}.$$

The variation of entropy is therefore expressed by a sum of three members which are plotted on the diagram from an inclined ordinate. The inclination of the line parallel to OX to the line parallel to OY varies with the value of b, while the chart to the right of the above-named line remains the same for all gases, due to the fact that all values are calculated on the basis of a mol, and therefore $\mathfrak{R}$ as well as a has the same value for all gases. The suction area located under the line AB is the amount of heat $\mathfrak{W}_v$ which must be supplied to one mol in order to increase at constant volume the temperature from T_0 to T. In order to express this amount of heat in terms of area, the values of $\mathfrak{W}_v$ are plotted as abscissæ to the right of point O on the vertical line, these values being

$$\mathfrak{W}_v = \int_{T_0}^{T} C_v dT = \int_{T_0}^{T} (a + bT)\,dT = (aT + \frac{b}{2}T^2) - (aT_0 + \frac{b}{2}T_0^2)$$
$$= \mathfrak{W}_b - \mathfrak{W}_a.$$

By repeating this process for various temperatures, one obtains the parabolic curve known as the heat curve. To the left of O the magnitudes $A\mathfrak{R}T$ appear as abscissæ.

At constant pressure the number of calories, which on the right-hand side of the diagram in Fig. 1 is represented by the enclosed area under curve AC, is equal to

$$\int_{T_0}^{T} C_p dT = \int_{T_0}^{T} (C_v + A\mathfrak{R})\,dT = \mathfrak{W}_v + A\mathfrak{R}\,(T - T_0) = \mathfrak{W}_c - \mathfrak{W}_{ap}$$

The spaces limited by the vertical lines at O and the line $A\mathfrak{R}T$ are therefore the differences between the amounts of heat at equal pressure $\mathfrak{W}_p$ and at equal volume $\mathfrak{W}_v$, which permits the careful determination of these two magnitudes.

Prof. P. Ostertag, of Winterthur, Switzerland, from whose writings the above scheme has been borrowed, uses the Stodola entropy diagram in a similar manner for the calculation of gas engines of all kinds. With all due respect to his work, however, it should be mentioned that the assumptions lying at the foundation of the above diagram are by no means universally satisfactory. In particular, the assumptions with respect to the specific heats are by no means free from objection. As has already been mentioned, it has been here assumed that $c_v = 4.67 + bT$. Here b for the simple gases H_2, N_2, O_2 and CO is equal to 0.00106, for CO_2 0.00568 and for superheated steam 0.00421; but such a manner of representing the function relation between heat capacity and temperature, while perhaps not objectionable for the first group of gases, is entirely insufficient for H_2O and CO_2. The specific heats of these subtances are very far from following the simple straight-line law, as has long ago been clearly demonstrated with regard to steam by the researches of Jakob, Knoblauch, Winkhaus and others.

It was therefore an important step in advance when, by carefully considering the available experimental data, Prof. W. Schuele, of Goerlitz, developed a diagram in which were shown the heats which must be supplied at constant pressure or volume to 1 cu.m. of air from 0 to 760 mm. in order to produce either a rise or fall of temperature. These heat values are computed in the following manner: If the temperature rises, for example from 0 deg. cent. to t deg. cent., the calories consumed at constant pressure $= \frac{m(c_{pm}) \times t}{22.4}$, where c_{pm} is the average specific heat in the respective region of temperature referred to 1 kg. of subtance and m is the molecular weight. Hence, $m(c_{pm})$ is the average molecular heat, and from this by the law of Avogadro the specific heat per cubic meter of substance may be obtained by dividing the above expression by 22.4. If the rise of temperature occurs at constant volume instead of constant pressure, as above, then the member c_{pm} is replaced by c_{vm}. In the Schuele diagram the heat values at constant pressure obtained in the above manner are shown as ordinates over temperature as abscissæ. Side by side with the curve for air is plotted another curve giving the same kind of values for pure "fire gas," i.e., the products of combustion generated when there is no excess of air. Between the air and gas line there are several broken-line curves representing more or less diluted "fire gas." The heat values at constant volume are

$$\frac{A\mathfrak{R}T}{22.4} = \frac{1.985\,t}{22.4}$$

less than the values at constant pressure. The new diagram replaces to a certain extent the left-hand portion of the entropy diagram of Stodola. Furthermore, it contains material which graphically represents the average molecular heats and the relation $\kappa = \frac{c_p}{c_v}$ for air as well as for the pure and diluted "fire gas." Schuele modified the right-hand part of the Stodola entropy diagram, which was the heat diagram proper, by plotting on the rectangular system of coördinates the p and v curves. While, strictly speaking, this diagram holds only for simple gases, it may be applied also to the products of combustion, provided only that one may assume there is present in them a material excess of air with only a slight content of steam. Thus, for example, there is no difficulty in representing graphically by means of the diagrams the processes that occur in the Holzwarth gas turbine.

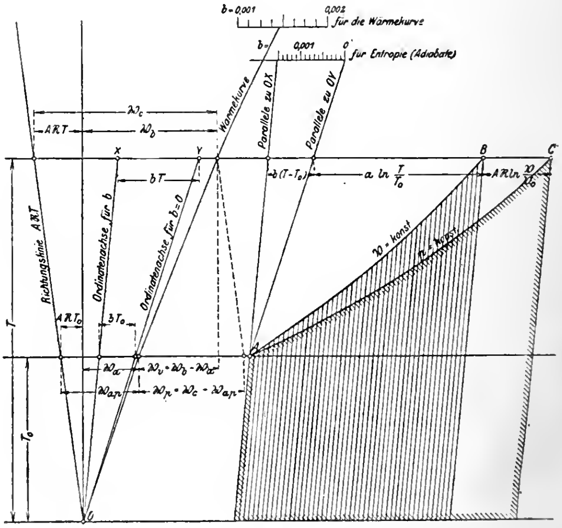

FIG. 1 STODOLA'S GAS ENTROPY DIAGRAM

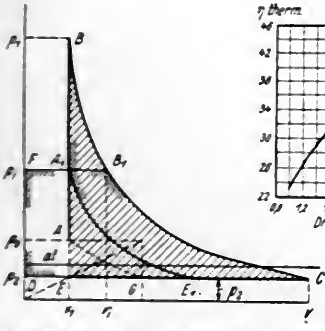
(*Richtungslinie* = line; *Ordinatenachse fuer* = axis of ordinates for; *Waermekurve* = curve of heats; *Parallele zu* = parallel to; *fuer die Waermekurve* = scale for the curve of heats; *konst.* = constant; • *fuer* = for.)

The curves obtained in this way become quite understandable if one takes into consideration in connection with them the pressure diagram of such a machine as is shown in Fig. 2, which, together with

Fig. 4, is taken from the second volume of Schuele's Thermodynamics which appeared in 1920. In the Holzwarth turbine the precompressed gas-air mixture is ignited in a separate chamber, and as a result of the explosion there occurs an increase of pressure at constant volume (AB). Then a valve opens and provides access to the turbine wheels, which the gas jet reaches after an expansion in a nozzle. If one should assume now that this expansion together with the pressure rise through combustion occur without any exchange of heat taking place, the expansion curve BC is an adiabatic. The gain in work through expansion is represented by the area BCE. Since back of the turbine there is a partial vacuum, C lies below the atmospheric line. There occurs a removal of the exhausted gases by suction which is represented by the line CE. If the exhaust gases have reached a temperature corresponding to the point G the air must first be brought down to a pressure of 1 atmos., and then the new gas-air mixture must be brought to the pressure GA which exists at the beginning of the explosion. The work of compression required for the above processes is represented by the area $AGDp_0$. It is now easy to understand the entropy diagram of Fig. 4. The explosion occurs at the point A'. The increase of pressure resulting therefrom is represented by the line of equal volumes $A'B'$. The area $A'B'B''A''$ corresponds to the total heat supplied as a result of the ignition of the mixture. The temperature of the point B' is found by reading from the heat-capacity-temperature diagram the amount of heating produced by the supply of heat generated by the explosion. The adiabatic of expansion is $B'C'$. The curve joining it indicates the partial pressure of the gas. The total gain in work is $B'C'E'$. The point E' is found in the same way as in the p-v diagram of Fig. 2—namely, by prolonging the iso-volume line $A'B'$ past A' until the intersection of the curve of pressures C'. When G' is reached compression begins and the work employed therefore is represented by the area under $G'A'$. It is delivered by a steam turbine driven by heat derived from the exhaust gases of the gas turbine. If the contents of the combustion chamber of the gas turbine were subjected to no precompression before explosion, they would have had, instead of the p curve through C', the line $C_1'A'$. The area $A'B'C_1'$, which now represents the gain of work, has decreased in size quite considerably, while the total heat supply has not changed. Therefore there has occurred a reduction in efficiency. If the back pressure has become smaller than in the previously considered case, it will be seen that the curve closing the circular process has moved further down. The area representing the work gained increases thereby, and so does the effective result. A drawing to scale would indicate that, with a back pressure of 0.9 atmos., a compression pressure of 3.15 atmos., and an explosion pressure of 19.8 atmos., there is obtained (assuming no other losses) a thermal efficiency, η, of 50 per cent. Even taking into consideration the fact that the waste heat does not provide sufficient power to take care of the gas compression, it would still appear that it is possible to convert into useful work from 40 to 45 per cent of the heat content of the materials of combustion. Such a result is no doubt very promising, as in reciprocating engines the ideal process leads to similar results only under the assumption of compressions in the ration of at least one to ten, and Holzwarth points to such conclusions of theoretical investigation with great gratification in his article of Feb. 28, 1920 in the *Zeitschrift des Vereines deutscher Ingenieure.* In this article he also uses the Schuele diagrams, but in the form employed they hold good only for air and very dilute gases, a defect which has since been corrected and does not appear in the diagrams of Fig. 4.



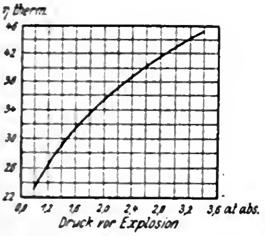


Fig. 2 The Process Occurring in the Holzwarth Turbine Shown in the p-v Diagram

Fig. 3 Efficiency of the Holzwarth Turbine Expressed as a Function of Precompression

(*Therm.* = thermal efficiency; *at. abs* = atomospheres absolute; *Druck vor Explosion* = pressure previous to explosion.)

It is to Schuele that credit should be given for this last step in advance in the theory of gas turbines. His diagram is of such great advantage in considering this new type of prime mover that it deserves a more complete description. Above all, it is remarkable for the great wealth of conclusions that may be drawn from it, notwithstanding its simplicity of appearance.

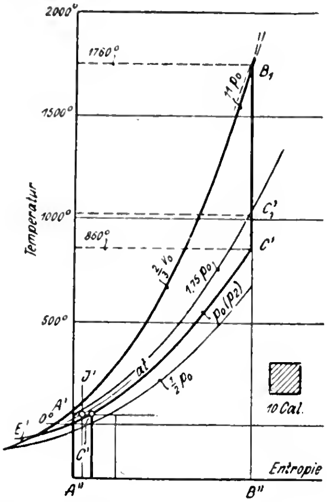

Fig. 4 Process of Holzwarth Turbine Plotted on a Heat Diagram

Schuele uses the following reasoning: From the expression already cited above, $dQ = c_v dT + Apdv$, it follows for any process occurring at constant temperature that $dQ = Apdv$, since dT is equal to zero. Furthermore, we have for cases of isothermal expansion and compression the equation

$$dS_T = \frac{dQ}{T} = \frac{Apdv}{T}$$

This, by reason of the equation of state, may be written as

$$dS_T = \frac{ARdv}{v}$$

from which we obtain by integration

$$S_T - S_{0T} = AR \log \frac{v}{v_0}$$

Furthermore, by differentiating the equation of state

$$pdv + vdp = RdT$$

and for constant temperature $pdv = -vdp$, and by introducing this last relation we obtain

$$dS_T = -AR\frac{dp}{p} \text{ or } S_T - S_{0T} = -AR \log \frac{p}{p_0}$$

From this it appears that the entropies at different pressures but the same degree of heat differ from each other by quite an appreciable amount, which moreover is independent of the temperature. At the same time all the curves of pressure are congruous and one may be derived from the other by displacing it by the amount given by the last equation. The consideration of the expression

$$S_T - S_{0T} = AR \log \frac{v}{v_0}$$

leads to the conclusion that all curves of volume are likewise con-

gruous, and each one may be derived from the other by a proper process of displacement. It is therefore sufficient to plot on the heat diagram only one pressure and one volume curve for a given substance, and indicate on the axis of abscissæ a scale from which for a smooth course of p_0/p and v/v_0 one may read the amount to which the given curve should be shifted for the given substance. It is, however, necessary to remember that different scales apply to different gases, but even this difficulty can be taken care of by carrying out calculations for the different gases in terms of mols. Should this be done and the molecular weight of the gas be denoted by m, the following equations hold good for the curves of pressure and volume:

$$m\,(S_T - S_{0T})_p = -\,LRm \log \frac{p}{p_0};\; m(S_T - S_{0T})_v = ARm \log \frac{v}{v_0}$$

However, according to Avogadro the product mAR for all gases is equal to 1.985 kg-cal. From this we find that

$$m\,(S_T - S_{0T})_p = 1.985 \log \frac{p}{p_0}, \text{ and } m\,(S_T - S_{0T})_v = 1.985 \log \frac{v}{v_0}$$

and from this it follows directly that if all calculations are made in terms of mols, the same scale applies to all gases. The same situation holds good if we consider the gas in terms of cubic meters at 0 deg. cent. and 760 mm. of mercury pressure. The weight of such a gas is $\frac{m}{22.4}$ kg. and the variation of entropy at the same pressure between the limits T and 273 deg. cent. is

$$\frac{m}{22.4} S_p = \frac{1}{22.4} \int_{273}^{T} \frac{mc_p}{T}\, dT = \Sigma_p$$

For equal volumes the analogous equation

$$\frac{m}{22.4} S_v = \frac{1}{22.4} \int_{273}^{T} \frac{mc_v}{T}\, dT = \Sigma_v$$

is found.

The displacements are therefore as follows, as a glance at the equations expressed in terms of mols would indicate:

$$\frac{m(S_T - S_{0T})_p}{22.4} = -\frac{1.985}{22.4} \times 2.306 \log \frac{p}{p_0} = -0.20405 \log \frac{p}{p_0}$$

$$\frac{m(S_T - S_{0T})_v}{22.4} = 0.20405 \log \frac{v}{v_0}$$

From this it would appear that the same scale holds good for all gases dealt with in terms of cubic meters.

For numerical calculations, however, it is necessary to make assumptions as to the specific heat c_p, c_v, the functional relation of which is given in accordance with generally known thermodynamic laws by the equation $mc_p - mc_v = mAR = 1.985$ kg-cal. For air and diatomic gases such as O_2, N_2, H_2, CO, the heat capacity referred to one mol is at constant pressure $mc_p = 6.57 + 0.00106\,T$. For one cubic meter we therefore get

$$\frac{mc_p}{22.4} = \mathfrak{C}_p = 0.2933 + \frac{0.4732}{10000}\,T$$

and since $\mathfrak{C}_p - \mathfrak{C}_v = \frac{1.985}{22.4} = 0.0886$, it follows that

$$\mathfrak{C}_v = 0.2017 + \frac{0.4732}{10000}\,T$$

From this it follows that

$$\Sigma_p = \int_{273}^{T} \frac{0.2933}{T}\, dT + \frac{0.4732}{10000} \int_{273}^{T} dT = 0.6754 \log \frac{T}{273} + \frac{0.4732t}{10000}$$

where $t = T - 273$. In a similar manner it is found that

$$\Sigma_v = 0.4713 \log \frac{T}{273} + \frac{0.4732t}{10000}$$

For all the substances above referred to it is sufficient to plot on the diagram one pressure and volume curve. Likewise, for all the pure gases of combustion generated by combustion with only the theoretically necessary amount of air present, the general equations

$$\Sigma_v = 0.7055 \log \frac{T}{273} + \frac{0.7143t}{10000}, \text{ and } \Sigma_0 = 0.5015 \log \frac{T}{273} + \frac{0.7143t}{10000}$$

hold with sufficient precision. In order, however, to determine the curves which would cover the case of diluted gases of combustion, one has to plot the Σ_p lines for air and the pure gases of combustion. Then the sections of abscissæ located between the two curves are divided in the ratio $\frac{v_e}{v}$, where v_e is the volume of the excess of air and v the total volume of the products of combustion. The points determined in this manner belong to the desired curves. The same process gives the v-curves for the diluted gases of combustion.

Schuele used an interesting graphic process described in the original article for determining the values of Σ_p and Σ_v for carbon dioxide and water vapor. (*Zeitschrift fur Dampfkessel und Maschinenbetrieb*, vol. 44, no. 44, Nov. 4, 1921, pp. 351–354, 4 figs., *tA*)

Short Abstracts of the Month

AERONAUTICS

TWO HUNDRED AND TWELVE MILES PER HOUR. In tests in December, 1921, at Martlesham, England, J. H. James is said to have established a record of 212 m.p.h., flying over the flying kilometer in a Mars-I machine made by the Gloucestershire Aircraft Co. However, the record has not yet been homologated by the Royal Aero Club. The machine is a biplane driven by a Lion engine. (*Flight*, vol. 13, no. 51/678, Dec. 22, 1921, p. 838, 1 fig., *g*)

WORK AT MCCOOK FIELD IN 1921, Maj. T. H. Bane, Mem.Am. Soc.M.E. Brief account of some of the outstanding features of the work of the Engineering Division, Army Air Service.

Among other things is mentioned the 1000-hp. engine now under construction. The engine is said to be of the barrel type and very compact.

Also a duralumin aeroplane has been built and passed its sand test, except for minor defects which it is believed will be corrected. This is the first attempt in this country to build a complete duralumin aeroplane. (*Aviation*, vol. 12, no. 2, Jan. 9, 1922, pp. 41–42, *g*)

FUNCTIONING OF SUPERCHARGER IN ALTITUDE FLIGHT, Lt. John A. MacReady. Excerpts from the report of the author on his flight at McCook Field, Sept. 20, 1921, which established a record for altitude. The flight was made on a supercharged LePere P-53 plane.

A peculiar and unusual condition arose during the flight. At the lower altitudes, instead of putting on the supercharger with altitude, it was necessary to gradually take off a little supercharger as altitude was gained. This is explained by the increase of speed of the propeller with altitude, resulting in increased supercharging capacity, which, if not taken off, would cause preignition. There did not appear to be an increase in propeller speed after 35,000 ft. was reached, and from this point on it was necessary to give additional supercharger to keep the supercharger altimeter dial indicating sea-level conditions.

On the ground the speed of the propeller was 1100 r.p.m., but gradually increased to 1680 at 35,000 ft. where it remained until an indicated ceiling of 41,200 ft. was reached. It was expected that the climb would be continued into some region of pressure above the point of 100 per cent supercharger efficiency, but this assumption proved incorrect. Sea-level conditions were reached at 40,100 ft., but from then on only slight altitude was gained, the supercharger dial registering a tremendous falling off. With 400 ft. more altitude, supercharging conditions within the engine went from sea level to approximately 6000 ft. above sea level, and this elevation became the absolute ceiling of the aeroplane. (*Aviation*, vol. 12, no. 2, Jan. 9, 1922, p. 51, *dA*)

AIR MACHINERY (See also Pumps)

Air Compressors for Marine Diesel Engines

Design of Air Compressors for Marine Diesel Engines, David Bruce. It being impossible to give any definite method of calculating, the first-stage cylinder volume in a marine Diesel engine is made a percentage of the total volume of the working cylinder. The percentage varies from 8 to 10 per cent. Practically all marine-Diesel-engine compressors are of the 3-stage type, though 2-stage machines are also employed as auxiliaries.

The article gives the figures for 2- and 3-stage machines, including the actual terminal figures in each stage, as resolved for final delivery pressures of 1015 and 1215 lb. per sq. in. abs., and also for initial pressures of 12 and 14.7 lb. absolute.

Methods of combining the various stages are described briefly and illustrated with diagrams. The valves used for the suction and discharge are of the automatic type and must be large enough to allow of a maximum air speed of 120 to 130 ft. per sec. through them. To keep within the speed limit in a large cylinder requires such a large valve capacity that in the larger stages two or three similar valves are fitted. In some of the pressure stages in which the diameter of the cylinder is very small, it is sometimes advisable to use small thimble and pocket valves. The article shows the inlet and outlet valves as adopted on small high-pressure stages (Fig. 1), the inlet being a mushroom and the outlet a thimble valve.

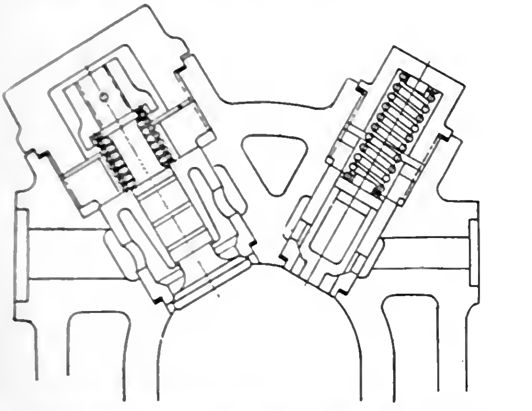

Fig. 1 Arrangement of Valves in Small Compressor Cylinders

The various types of air intercoolers are described briefly and illustrated.

Discussing clearance volumes, the article states that these must be kept as low as can be arranged in accordance with working conditions, although the practice of omitting certain valves, such as the 2-stage delivery valves in small marine compressors, and allowing the next stage suction valves only to provide the separation between the two stages, is undesirable as it leads to a big drop in efficiency of the compressor. (*Motorship*, vol. 7, no. 1, pp. 22–24, 11 figs., *d*)

Handling Material by Compressed Air, F. A. McLean. Description of various types of air hoists, of particular interest on account of the inclusion of several tables of figures giving the cost of hauling and lifting with this type of hoist. (*Canadian Machinery and Manufacturing News*, vol. 26, no. 25, Dec. 22, 1921, pp. 19–23, 10 figs., *gp*)

COMBUSTION ENGINEERING (See Aeronautics)

CORROSION

Corrosion of a Producer-Gas Cooling System, Lloyd E. Jackson. Data of an investigation conducted for the Providence Gas Company, Providence, R. I., at the Mellon Institute, Pittsburgh, Pa.

The incentive for this investigation was that at the manufacturing plant of the Providence Gas Company, after six months' operation with coke some producers developed leaks in the producer-gas cooling-water system.

There were good reasons to believe that the corrosion was not due to electrolysis caused by stray electric currents. Acids which might also lead to corrosion were found in numerous samples. The most economical way to treat acid is to neutralize it with lime, but before commencing to give this treatment to water some carefully cleaned test pieces of iron 5 in. by 2 in. by $^1/_8$ in. were suspended in the cooling system at the same points from which water samples were collected. The test pieces were allowed to remain several days and then were removed, dried and weighed. This test was made to obtain data with which to compare future data to be obtained from tests made following successful steps in treating.

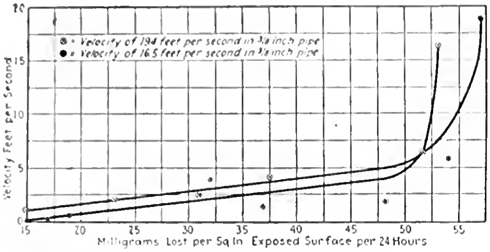

Fig. 2 Erosive Action of Cooling Water Containing Suspended Coke Dust

Apparatus for treating the water with lime was next installed, the water being at first treated with sufficient lime to make it alkaline to methyl-orange indicator. Tests with suspended iron test pieces showed that the corrosion of iron in water so treated was about half as great as in untreated water. However, methyl orange indicates only free mineral acid, and an attempt was made next to treat the water with sufficient lime to maintain it alkaline to phenolphthalein, which latter shows also acidity caused by dissolved carbon dioxide. This did not prove practical because such amounts of carbon dioxide are present in the producing gas with which the cooling water comes in direct contact; that reasonably large amounts of lime would be required to maintain the water alkaline to phenolphthalein.

Numerous analyses of samples were made also for dissolved oxygen, and they showed that the city water used for making up evaporation losses was highly saturated with dissolved oxygen. Further, as the water gives up its dissolved oxygen in the gas-cooling system, it is continually receiving a fresh charge when sprayed into the cooling pond. Dissolved oxygen, however, is an active corrosion agent, both in neutral and acid solutions and is particularly active in the presence of free mineral acids. To free the cooling water of dissolved oxygen, it was proposed to pass it through filters containing steel turnings instead of coke. Tests with suspended iron pieces showed that such an arrangement cut down corrosion in half. Tests were further made to determine the erosive action of the suspended coke dust in the cooling water. The results are presented in a table in the original article and plotted against water velocity in Fig. 2. From this test it appears that erosion due to suspended coke dust and ashes plays a very important part of the deterioration of the cooling system. In fact, in tests with 6-in. service pipe and a velocity of flow of water of approximately 12 ft. per sec. under average operating conditions, erosion tests showed this pipe to be wearing away at the rate of 55 mg. per sq. in. per 24 hr. The following recommendations were suggested as possible remedies for preventing deterioration of producer-gas cooling system:

(1) Cool and clean the producer gas with fresh water, and permit the water to waste to the bay after going through the cooling system. (2) Treat, cool and recirculate fresh water. The treatment recommended consists of filtration to remove suspended coke dust, neutralization of free mineral acid with lime, and removal of dissolved oxygen with steel turnings. (3) Cool and clean the gas with an excess of bay water and let it waste back to the bay.

In commenting upon these recommendations the author calls attention to the fact that first cold deactivated bay water had no

appreciable corrosive action on iron, but in the presence of hot producer gas, iron in deactivated bay water corrodes about three-fifths as rapidly as in the presence of raw bay water, and that the corrosive action of either kind of water increases rapidly as the temperature rises.

When 60 deg. fahr. or cooler water is available, the producer gas can be cooled sufficiently by pumping the cold water over the condenser and pumping warm water from the decanter over the dust catchers and collecting main. To determine whether warm bay water causes greater corrosion under these conditions, weighed pieces of iron were suspended on the bottom of a dust catcher and permitted to remain there for 14 days; then they were removed and reweighed. Water entered the dust catcher at a temperature of 100 to 110 deg. fahr. and left at a temperature of 110 to 120 deg. fahr. The tests show that practically the same amount of corrosion takes place in the dust catcher as when cold water which has not been deactivated is pumped. This recirculation, whether with bay water or fresh water, should not be practiced, because the water when tested contained excessive amounts of suspended coke dust. Under these conditions it is to be expected that pipes and pumps carrying the water from the decanter to the dust catchers will erode rapidly. Bearing out this contention, several leaks developed while test 6 was in progress.

Tests made to compare bay water with unfiltered recirculated fresh water have shown that the advantage lies with bay water. (*Chemical and Metallurgical Engineering*, vol. 26, no. 2, Jan. 11, 1922, pp. 60–64, 5 figs., *eA*)

COST ESTIMATING (See Foundry)

ENGINEERING MATERIALS (See also Railroad Engineering

Bentonite, Raymond B. Ladoo. The name "bentonite" has been applied to a series of claylike materials which occur in Wyoming, California and South Dakota in fairly large deposits, as well as in several other states.

It is coming into use for certain purposes in several industries, including its employment as a water softener. No detailed data as to this latter use are given. (*Chemical Age*, vol. 29, no. 12, Dec., 1921, pp. 493–494, *g*)

Metallurgy of Gray Cast Iron

The Problem of Gray-Iron Castings, H. J. Young. The author recommends the necessity of closer control of iron castings, beginning with the ore used for the pig iron. With the aid of tables he shows how such control is possible—in fact, he claims that purchasing an iron today upon its published composition is buying "a pig in a poke." Pig iron of standard ultimate composition would solve nearly all the difficulties of the jobbing foundry and most of those doing more important work.

Regarding the use of an electric or other furnace in conjunction with the cupola (duplexing), he says, first, that what we know about cupola practice is insufficient to enable us to predict that it cannot by itself give what we require. Next comes the question of cost, especially where competition with foreign markets (the abstract is from a British paper) has to be considered. Finally, it should not be assumed without question that the more carbon, phosphorus and sulphur abstracted from the iron, the better will be the metal for the purposes of making castings.

The author considers gray cast iron as a very high-carbon steel, cut up by and surrounding innumerable plates of graphite—in other words, a matrix of steel containing many spaces filled with graphite. This is why cast iron can be machined, the non-homogeneous material collapsing under the stresses produced by the edge of the cutting tool. For the same reason cast iron has little or no elongation.

The truth of these generalizations is well illustrated in the case of a large propeller casting, blades and boss complete, and weighing, say, 11 or more tons. Here the great mass of the boss causes extremely slow cooling of the adjacent parts, the effect getting less and less along the blades away from the boss and also as the cross-section of the blades themselves gets less. In practice, the molten metal flowing to the tips of the blades is almost chilled, and therefore the tips are very hard and brittle and contain but little free carbon. A short distance from the tip this cooling is less severe and more carbon is released, with the consequence that the metal is gray but rather hard. Half way up the blade the section is greater, and the heat given off by the cooling of the boss delays the cooling, hence the metal will be very normal and perfectly gray and machinable. At the root of the blade, where it joins the boss, the cooling will be extremely slow, taking some hours probably, and therefore the iron has time to free itself almost entirely from combined carbon, and when cold is found to be full of large graphite.

Thus does a propeller casting demonstrate the fact that the quantity and size of the graphite is greatly ruled by the rate of cooling of the metal from hot solid to cold solid. It shows how impossible it is to expect a test bar to represent anything but that part of the casting from which it is cut.

The author cites other examples to show that there is a material difference between metal cast in thicknesses of 4.5 in. and of 1 in. This difference would also appear in test bars cut from such castings. (Paper read before the Inst. of Mining Engrs., Dec. 13, 1921, abstracted through *Foundry Trade Journal*, vol. 24, no. 279, Dec. 22, 1921, pp. 497–501, 10 figs., *ep*. To be continued.)

FOUNDRY (See also Engineering Materials)

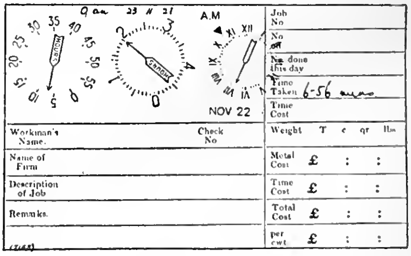
Foundry Costing

Foundry Costs and Establishment Charges, Daniel Adamson, Mem.Am.Soc.M.E. Discussion of the method of determining costs and establishment charges, with particular reference to British conditions. The indirect charges are divided as between the molten metal and the labor expended on the mold, and are a matter to be estimated for each particular establishment. They should be ascertained at regular intervals, say, every four weeks, and can then be allocated somewhat as follows:

Unallocated labor: 25 per cent of this item to be charged to "metal" and 75 per cent to workmanship account.

Power: 50 per cent to metal and 50 per cent to workmanship.

Light: 20 per cent to metal and 80 per cent to workmanship.



Job No

No off

No done this day

Time Taken 6-56

Time Cost

Workman's Name. Check No

Weight T c qr lbs

Name of Firm

Metal Cost £ : :

Description of Job

Time Cost £ : :

Remarks.

Total Cost £ : :

per cwt £ : :

Fig. 3 Job Record For Foundry

Foremen's wages: 20 per cent to metal and 80 per cent to workmanship.

Clerical charges: 25 per cent to metal and 75 per cent to workmanship.

Maintenance of buildings, machinery and plant, mill stores and sundries: 25 per cent to metal and 75 per cent to workmanship.

Depreciation and obsolescence: 25 per cent to metal and 75 per cent to workmanship.

Bank charges: 50 per cent to metal and 50 per cent to workmanship.

Taxes, rates, and insurances: 15 per cent to metal and 85 per cent to workmanship.

Indirect charges can then be converted into percentages of the totals expended during the period for materials and direct labor, respectively. For ascertaining the cost of a particular casting made during that period the percentages would be added to the net cost of material and labor, respectively, and a further sum cover contingencies and profits.

The net cost of materials would include the value of everything charged into the cupola such as pig iron, scrap, coke, limestone. The net cost of workmanship should include as much time as can be booked directly to the job, particularly molders' and coremakers',

also molding-machine time and, in some foundries, dressers' time also. To make the suggestion clearer, an example is worked out, using imaginary figures for purposes of illustration only.

In arriving at the cost of skilled labor booked directly to the job, and upon which the calculations of cost are to be based, attention should be given to the accuracy of the records made, and the most reliable method appears to be that in which job tickets are issued by the foreman to the workman, who in turn stamps these in a time clock at the beginning and end of his time on the order. A typical example of a suitable ticket is given in the article (Fig. 3).

By using the clock in this manner remarkable discrepancies in previous records were discovered, and the conclusion reached that the usual methods of booking time, whether dependent upon the observation of the foreman, or a clerk, or upon the memory or imagination of the workman, are quite illusory and so unreliable as to be almost useless. While the job-ticket system is of great value in other departments of engineering, it is particularly advantageous in a foundry, where it acts also as a check upon the quantity of bad castings made.

The remainder of the article is of interest primarily to British foundrymen. (*Engineering*, vol. 112, no. 2922, Dec. 30, 1921, pp. 894–895, 1 fig., *p*)

Giant Cupola and Molding Big Turbine Runners, E. C. Kreutzberg. The I. P. Morris Foundries of the Wm. Cramp & Sons Ship & Engine Building Co., Philadelphia, Pa., have specialized in the production of castings for water turbines. Runners have already been cast weighing 93,000 lb. finished, and still larger castings of the same character to weigh as high as 160,000 lb. are expected shortly. Such huge castings require corresponding foundry equipment, particularly as turbine runners must be very carefully balanced when in use and therefore must be cast with weight uniformly distributed.

Unless the entire casting is made of material at about the same temperature, there is danger of internal stresses being set up. With the ordinary foundry equipment, however, this can hardly be avoided, as hitherto there were no single cupolas capable of giving enough metal for such large castings.

To meet this condition a special cupola was installed capable of delivering 14,000 lb. of molten metal every 15 minutes. The cupola has a shell diameter of 108 in. with a diameter of 84 in. inside for the lining, which is at least 3 ft. greater than the lining diameter of the average cupola. It is claimed that there is only one other cupola of the same size and type in use.

For casting turbine runners an unusual mold is required. Aside from the bottom plate and cover plate, the mold is made up entirely of cores. These are 16 in number and their sides correspond to the 16 veins in the casting. The job of setting up the mold is not an easy one. The cores cannot vary $^1/_{16}$ in. from the correct dimensions, and must then be set with absolute precision. Each core is set to overlap the next, and after they have been assembled sheets are placed around the mold and sand rammed between the sheets and the cores. The total weight of the mold with the casting is 135 tons. The construction of the 93,000-lb. turbine runner mold required 28 days. (*Foundry*, vol. 50, no. 1, Jan. 1, 1922, pp. 6–8, 3 figs., *d*)

FUELS AND FIRING (See also Internal-Combustion Engineering)

The Turbo Pulverizer. Description of a machine representing the self-contained unit for powdered-fuel firing, used in several important plants in England and on the continent of Europe.

The unit provides a pulverizing mill and fan combined. It comprises a rotor revolving on a horizontal axis in a steel casing. This casing is divided into compartments—the one nearest to the delivery containing a blowing and exhausting fan, while the other contains paddles fitted with loaded blades which, acting by impact, crush and pulverize the coal in stages. The coal is fed into the machine by an adjustable revolving table, the feed regulating the amount of coal burned in the furnace. The air is admitted at two points.

At the works of Edgar Allen & Co., Ltd., of Sheffield, England, the turbo pulverizer operates in connection with a first-heating furnace in the forge, and according to the article reviewed the consumption of fuel was cut nearly in four. No banking through the night is now used, and on restarting in the morning the heat can be brought up in two hours, or from stone cold in three hours.

Advantages of this type of equipment are quoted as low initial price and the fact that fine slack coal can be used with fairly high ash and moisture content too high to be employed for other purposes. (*The Iron and Coal Trades Review*, vol. 103, no. 2807, Dec. 16, 1921, pp. 887, 1 fig., *d*)

HYDRAULICS

The Variation of Energy About a Point in a Rotating-Type Hydraulic Machine, M. Eydoux. In a previous investigation published in the *Comptes Rendus de l'Academie des Sciences*, Oct. 24, 1921, the author has shown that when there occurs a variation of energy along a liquid passage in motion, as happens in turbines and centrifugal pumps, there must of necessity be present a gyratory vector. Working along the same lines, but considering the case of a rotating-type hydraulic machine, the author determines a vector expression for the variation of energy along a line of stream of the liquid.

The author establishes the proper equations for this in terms of the various velocities of flow, and finds from these equations that the components of absolute velocity and the turbulence velocity located in the meridian plane are the only magnitudes determining the variation of energy. As water is a viscous liquid and all turbulent motion which does not turn the machinery is simply a loss of energy, it is obvious that it is desirable to avoid all flow which might give rise to turbulence in an axis normal to the meridian plane.

This treatment of the question makes it possible to express as a function of T (velocity of turbulent flow) the components at one point of the reaction due to the wheel blades expressed in terms of unity of masses, and in this way to find in expressions of usual notation the results previously obtained by Bauersfeld and Lorenz. From these it appears that the reaction of the blades is normal to the relative velocity. If we consider, however, a meridian plane and a section of the blade in this plane, we will find that the work of reaction along that line is zero. Hence the meridianal component of reaction is normal to the section of the blade, which holds good also for the reaction, which being perpendicular to the two curves in the blade is therefore normal to the blade itself. Further discussion of the same subject indicates that the turbulent motion being perpendicular to that of reaction is tangent to the blade.

The article is of a mathematical character not conveniently suitable for abstracting. (*Revue Générale de l'Electricité*, vol. 10, no. 25, Dec. 24, 1921, pp. 907–908, *m*)

INTERNAL-COMBUSTION ENGINEERING (See also Air Machinery, Aeronautics, Railroad Engineering)

Novel Control of Velocity of Combustion in Automobile Engines—Carburetor with Thermal Regulation

A Chemically Controlled Automobile, Geo. Granger Brown. The author discusses briefly the known conditions covering thermal efficiency, and proceeds to the consideration of the reaction velocity, stating that essentially the factors determining the speed of combustion are concentration, temperature and agitation or turbulence. To these he adds catalysis.

For the influence of concentration he derives an equation from which it would appear that so long as the composition of the atmosphere remains constant, its oxygen content has no influence on the gasoline content giving maximum velocity of reaction as far as the law of mass action is concerned.

With the temperature factor the situation is different. The rate of chemical action increases very rapidly with the rise of temperature, and the maximum temperature with such fuels as are used in automobiles is produced by the mixture containing fuel vapor and oxygen in combining proportions. This factor of maximum temperature acts, therefore, in opposition to mass action and tends to decrease the excess of gasoline in the mixture of maximum-reaction velocity demanded by mass action, to an extent depending upon the cooling effect or the specific heat of excess gasoline. But the

mixture of maximum reaction velocity of any combustible gas and air has always an excess of the combustible constituent over the combining proportion due to the influence of mass action (Fig. 4). Fig. 5 shows the more intense and more rapid combustion of a mixture of 12 parts of air (curve *B*) over that of a lean mixture of 16 parts of air (curve *A*) as occurs in an engine cylinder, all other conditions being constant.

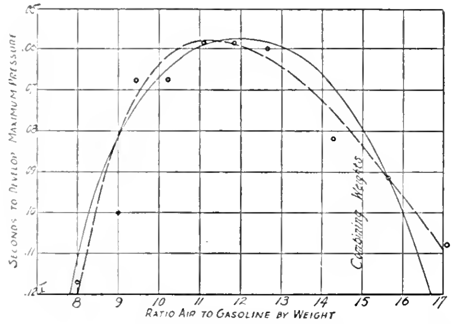


Fig. 4 Velocity of Combustion of Gasoline-Air Mixtures

Furthermore, increase in the temperature broadens the limits of explosive mixtures and renders explosive mixtures otherwise non-explosive.

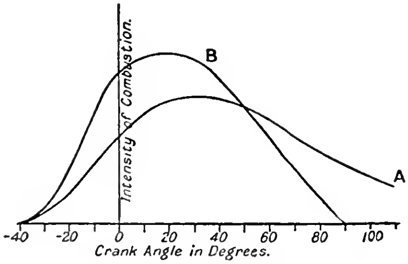

Fig. 5 Intensity and Velocity of Combustion of 12 : 1 and 16 : 1 Air-Gasoline Mixtures

Fig. 6 shows the results of presence or lack of agitation obtained on an indicator card after two idle compression strokes in which the turbulence was allowed to die down. The curve *AB* corresponds to normal firing and the expansion line *A′B′* corresponds to the second case in which all conditions except decreased turbulence were the same.

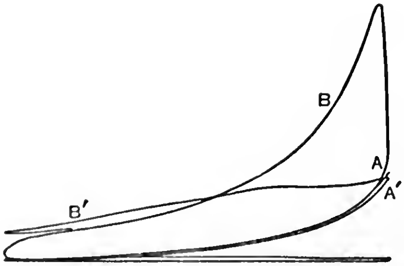

Fig. 6 Indicator Diagram of Turbulent and Quiet Mixtures

Pressure has been found to have practically no influence upon speed of reaction, so long as temperature remains constant. However, increased compression in an engine means increased temperature, since the absolute temperature varies as the absolute pressure in adiabatic processes.

In addition to the complete combustion of gasoline, partial combustion to aldehyde, carbon monoxide, and possibly hydrogen, also takes place, along with some decomposition of the hydrocarbon fuel.

The stability of the hydrocarbons is greatest with the lowest paraffin—methane. Ethane is less stable and can be very rapidly decomposed at 1100 deg. cent. It has been estimated that at 1500 deg. cent., 0.036 sec. is the time required for complete decomposition of the hydrocarbons. At this temperature, which is attained in the gasoline engine, the time of decomposition is of the same order as that of the ignition period.

These two reactions are taking place simultaneously in the cylinder as the mixture is exploded, combustion producing heat and work, and decomposition of the gasoline generally absorbing heat and depositing carbon residue. As decomposition of the fuel takes place much more rapidly at higher temperatures, the lower temperature developed by the combustion of lean mixtures is of advantage in decreasing and eliminating fuel knock and also deposition of carbon in the cylinders. Sir Dugald Clerk has accomplished the same result by introducing cold exhaust gas into the cylinder charge. This method is more effective in reducing the temperature, but probably not so efficient, owing to the higher specific heat and radiation loss of carbon dioxide over air. Also, it introduces complications in the design and operation of the engine.

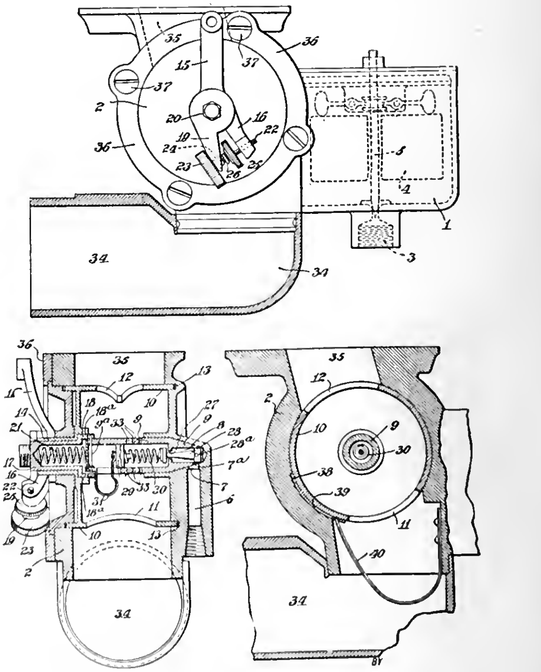

Fig. 7 Construction of Carburetor Giving Automatic Control

The author carried out a series of tests to determine the action of a gasoline engine subjected to various conditions of temperature and concentration of mixture.

The most interesting parts of these tests are those made with the carburetor shown in Fig. 7. The gasoline enters the float chamber 1 at 3 and passes through duct 6 up to the gasoline valve made by part 7 in the casing and part 7*a* in the stem valve 9, which is in the axis of the drum throttle 10 containing the air inlet 11 and the mixture outlet 12. The gasoline valve can be adjusted in relation to the throttle by the thumb screw 23 and locked in place by the nut 20, so that when the throttle lever 15 is moved the gasoline valve moves in unison with the throttle. The mixture outlet and air inlet are so calibrated that the suction in the mixing chamber is constant so long as the engine is running under "normal load." If the engine is running under any load greater than "normal" for that particular throttle position, the suction in the manifold and the mixing chamber will be less.

This variation in the manifold suction is utilized to vary the

mixture proportions in the following manner: Within the valve stem 9 is an opening, 27, in which the governor 28 is free to reciprocate endwise of the valve stem 9. This governor 28 has a taper shank which restricts the effective area of the opening 27 by an amount corresponding to the section of the taper shank of the governor which happens to be within the opening.

The stronger the suction in the mixing chamber, the stronger will be the flow of fuel and the greater will be the restriction of the opening 27, as the pressure of fuel flow upon the head of the governor compresses the spring 30, making the larger part of the taper effective and to that extent closing the fuel opening 27.

The position of the governor is also controlled by the position of the sliding block 29. The position of this block 29 is determined by the bimetal thermal regulator 31, which is fastened to the valve stem at one end and at its other end rests in a socket in block 29. Upon an increase in temperature the thermal regulator 31 curls up in a direction to move block 29 to the left and permit the governor 28 to move a like distance toward the left, thereby restricting the opening 27 an amount proportional to the movement of the thermal regulator. Upon a decrease in temperature the thermal regulator uncurls, causing the governor 28 to move a like distance toward the right, and exposing a greater effective area of the opening 27.

It has been found possible to calibrate this governor and thermal regulator to obtain automatically any desired change in mixture proportion upon change in engine load or change in temperature. It is possible to compensate simply for the decreased density of air and decreased viscosity of fuel with increasing temperature, or further to restrict the flow of gasoline so as to obtain always the leanest possible or most efficient mixture. Likewise the change in mixture proportion with changing engine load may be simply sufficient to compensate for decreased turbulence to prevent missing and backfiring; or may be sufficient to change from the most economical or efficient mixture under normal conditions to the most powerful mixture when the engine is heavily loaded.

This carburetor is supposed to deliver a definite mixture of gasoline and air for each condition of temperature and load. (Paper before the Division of Industrial and Engineering Chemistry, American Chemical Society, September, 1921, abstracted through *The Journal of Industrial and Engineering Chemistry*, vol. 14, no. 1, Jan., 1922, pp. 6–12, 20 figs., *ted*)

MACHINE PARTS

Belting Argument Decided by Cornell Tests. Late in the summer of 1921 tests of the capacity of the grain and flesh sides of leather were begun by the Leather Belting Exchange in its research laboratory at Cornell University. These tests were carried on under the direction of R. F. Jones, director of the laboratory, and covered a period of two months of continuous work.

For the experiments five 4-in. single belts 30 ft. long were used. They came from various manufacturers and weighed from 16 to 18 oz. per sq. ft. Every effort was made throughout the tests to standardize conditions and reduce the probable errors to a minimum. All five belts were run long enough before the experiment to be thoroughly "run in," and when the records were taken had reached a condition of constant capacity.

The method of procedure was to take horsepower readings from the belts, first when running on the grain side and then when running on the flesh side, the power being gradually increased until about 4 per cent slip was reached.

In considering the results it must be remembered that a leather belt is at its lowest point of capacity when new, due partly to the elasticity of the leather and partly to the character of its surface. The newness of the surface makes it necessary to "run in" the belt when testing it; that is to say, the belt must be run for a sufficient time to permit it to reach its maximum capacity for power transmission. As an example, one belt under test at the Cornell Laboratory transmitted 12 hp. at a slip of 1.2 per cent when first put on the pulley. After five hours' running it reached 19 hp. with the same percentage of slip and the same tension. At the end of 13 hours it transmitted 24 hp., and 31 hp. after 20 hours, with a slip of 1.6 per cent. According to horsepower tables the scheduled transmission should have been 26 horsepower.

Space prevents a review of the results of the individual tests, but they indicate clearly the superiority of the grain side. Under reasonable shop tension the flesh side will average only 50 to 60 per cent as much horsepower as the grain side. At higher tensions, however, the flesh side will average from 50 to 100 per cent as much power as the grain side, depending on the belt, the tension and the conditions of service. (*Power*, vol. 55, no. 2, Jan. 10, 1922, p. 66, *d*)

MACHINE SHOP (See Management)

MACHINE TOOLS

Attachment for Cutting Spur Gears on the Shaper. Description of a device placed on the market by a British firm (the illustration in the original article is not suitable for reproduction). The attachment operates on the generating principle, so that single-point tools cut from the bar and ground to a straight-sided rack form are employed. Gears of module, circular or diametral pitch, can be readily cut, the tools being ground to graduated gages. The attachment is intended primarily for use with single-point tools, but rack-form cutters with multiple teeth can be used also. Stepped cluster gears, such as are commonly used in motor-car gear boxes, can be readily handled on this attachment, though frequently impossible of access with milling cutters.

The attachment is said to be readily applicable to standard-type shapers. The only permanent alteration to the shaping machine is the cutting of a spline in the cross-feed screw to receive a pinion $2^1/_4$ in. in diameter. The existing feed motion is utilized, the cross-feed screw being geared up through change wheels and a chain and sprocket transmission to a 60-tooth $^3/_8$-in. pitch steel-worm dividing gear. The combined sliding on the cross-slide and turning on the worm wheel produces a rolling motion. The dividing is effected by hand, through a dividing plate and plunger mechanism. (*Engineering Production*, vol. 3, no. 64, Dec. 22, 1921, pp. 587, 1 fig., *d*)

MANAGEMENT

Conditions Governing Fatigue of Workers—Wattmeter Method of Measuring Human Effort in Polishing Work

Motion Study in Metal Polishing. Data of an investigation, by means of a wattmeter, of the process of roughing, carried out under the auspices of the Industrial Fatigue Research Board in England. The instrument used is a recording wattmeter giving a continuous graphical record of the amount of electrical energy expended by the motor in use.

In the roughing process (removing imperfections and scratches from the surface and edges of the metal by means of a wooden wheel covered with a leather tire and rotating at a high speed), the thrusting of the article against the buffing wheel results in a frictional retardation of the wheel, and the amount of energy expended by the motor to overcome this friction is accurately marked upon the chart.

From the nature of the process this friction cannot be caused passively. The operator cannot just lean the article being roughed, a table spoon in this case, against the wheel, and therefore must exert effort, and the amount of friction produced is directly dependent upon the effort. Hence the height of the individual strokes above the zero line (energy expended by the motor in revolving the buffing wheel idle) made by the pen of the wattmeter on the chart can be assumed to correspond to the amount of effort put forth by the operator (rougher).

Since the wattmeter records every stroke of the rougher against the wheel and also every pause between the strokes, a graph such as Fig. 8 is automatically obtained, giving the complete time study of the operation under investigation.

Each operator in turn was set to work at the spindle driven by the motor to which the wattmeter had been attached and was observed at her work for two days, during which time she was kept supplied with spoons. In analyzing the records, detailed examination was confined to the roughing of the backs of the bowls. This particular portion of the spoon was selected, first because the surface is large and therefore likely to give evidence of any fatigue that may exist; second, because long heavy strokes are generally applied, and third,

because the work is not complicated by any difficult corners or pattern.

The following method was adopted in examining these charts. The total time taken to rough four bowls, and the average time per bowl was ascertained from the wattmeter records. The number of strokes per spoon was counted and each stroke measured, and in this way the average length of each stroke in centimeters on each record was obtained. Finally, the time taken on each four bowls was divided by the total number of strokes, thus giving the average duration of each stroke.

The results obtained from two of the operators are given in a table in the original article. From this it would appear that one of the operators exerted a far greater pressure than any of the others. As the work of a second operator was, however, of excellent quantity, it would appear that the additional pressure exerted by the first was simply unnecessarily fatiguing her, and at the same time wearing out the roughing wheel.

The examination of these tables shows further that in all instances the time taken to perform a unit of work increased toward the end of the day. The number of strokes made by each worker was about the same, but the height of each stroke, which is a comparative measure of the pressure exerted, showed a marked tendency to increase during the afternoon. The duration of the stroke also increases during the day, especially in the late afternoon; this would indicate that the operators growing tired were inclined to give more vigorous strokes and take longer over each individual stroke.

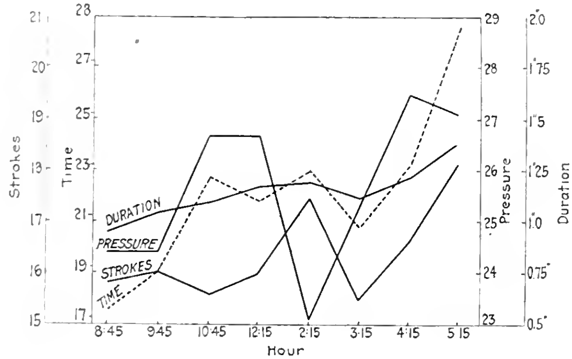

Fig. 8 Duration, Pressure and Strokes in Roughing Four Table Spoons Compared with Time Required

Two factors are present which together determine the duration of the stroke, namely, the length of time that the pressure of the spoon against the wheel is sustained, and the length of the pause between successive applications of this pressure. An examination of the charts shows quite clearly that both these factors were in operation, and that toward the end of the day's work both operators made more sustained strokes, and also paused for a longer time between each stroke.

Another method of measuring the wattmeter records was used, in which the areas enclosed by the recording pen of the meter were measured by a planimeter. These measurements give the energy expended by the motor in order to overcome the frictional retardation caused by the worker pressing the spoon against the revolving wheel, and so give an approximate measure of the human effort exerted.

The records obtained by the first method lead to some interesting conclusions. Fewness of strokes corresponds very closely with high output, or, in other words, implies increased duration and good pressure if good output is to be maintained.

The accounts of earlier experiments carried out in time and motion study have described the large part played by rhythm in the easy performance of most industrial operations, and probably rhythm is the determining factor in this case too. In the earlier part of the day, when the worker is fresh, the work is done rhythmically and the results are satisfactory. The nearest approach that can be made to instill rhythm is by modifying the number of strokes. It will be seen that the number of strokes per spoon varies little in the morning, and that greater variations are introduced in the afternoon. When fatigue increases, the natural rhythm of the body seems to break down and conscious effort is invoked in order to do this work.

The records of the present tests would indicate, however, that as the worker becomes fatigued, the coördination between the factors represented by the curve of rhythm becomes more and more disturbed. Fatigue has the effect not only of slowing the reaction times, but also of causing a certain lack of motor control, resulting in increased pressure and increased number of strokes. The tired worker is not only working slower than when she is fresh, but is also expending her energy extravagantly. From this it would seem that in order to increase the efficiency of certain industrial operations, attention must be paid not to speed nor even to the elimination of unnecessary movements as an end in itself. The first thing to do is to devise a rhythmic method of doing the work, which may be done by means of limiting the number of strokes. Then proper instructions must be given to the method.

The present experiments have shown that other factors besides the lack of rhythm make for fatigue, such as putting too much effort into the work. (*Engineering and Industrial Management*, vol. 6, (New Series), no. 26, Dec. 29, 1921, pp. 738–742, 3 figs., *ep*)

MEASURING APPARATUS

Pressure-Corrected Recording Steam Meter

The Kent-Hodgson Steam Meters, J. L. Hodgson. Description of steam meters developed by the writer together with a British concern.

Fig. 9 shows in a diagrammatic form the essential parts of the pressure-corrected steam meter. An orifice, *O*, is placed in the steam main and creates a difference of pressure $(p_1 - p_2)$ which is transmitted through the pressure pipes, *PU* and *PD*, to the two sides of the battery of diaphragms, *DP*, in the recorder. These diaphragms are held apart by a spring, *S*, so that any increase in the difference of pressure causes them to come together. Their motion is transmitted through the gland *G* to the slotted arm *B*, which is pivoted at *C*. In this way *B* is given an angular motion, which is proportional to the difference of pressure existing across the orifice. The pressure of the steam is transmitted through the pipe *PU* to the tempered steel diaphragms *P*, which expand with increase of pressure and give the pointer *Q* a motion proportional to the pressure. This motion causes the connecting rod *H*, which carries the roller *R*, to descend an equivalent amount. The motion transmitted through the connecting rod *H* to the pen arm *A* is thus proportional to the product of the angular motion of the arm *B* [which depends upon $(p_1 - p_2)$] and of the linear movement downward of the roller *R* [which depends upon the absolute pressure of the steam p_1].

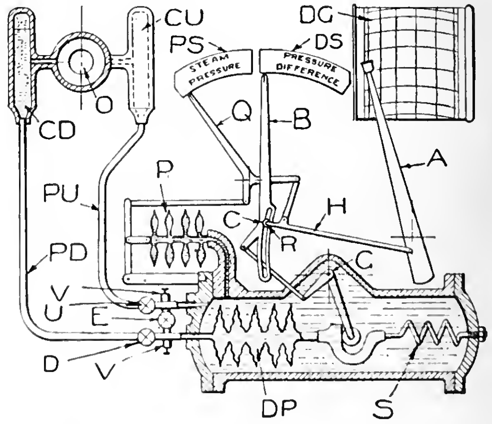

Fig. 9 Diagram of Essential Parts of Kent-Hodgson Steam Meter

If the superheat of the steam be assumed constant, the formula

$$Q = K\sqrt{(p_1 - p_2)\,p_1} \text{ pounds per hour}$$

(where K is the constant depending upon the size of the orifice and the size of the main, and upon the superheat or wetness of the steam) represents approximately the steam flow through an orifice, so that if the diagram DG is divided on a square-root basis it will show

$$\sqrt{(p_1 - p_2)\,p_1}$$

or by suitably numbering the lines on the diagram it will show

$$K\sqrt{(p_1 - p_2)\,p_1}$$

i.e., Q.

Actually, the law of steam flow through an orifice is slightly more complicated than that represented by the above formula. The meter is made to operate according to the true and more complex formula by correctly adjusting the initial angles of the various cranks.

Scales PS and DS, showing the steam pressure and the pressure difference across the orifice, are provided, which enable the adjustments of the meter to be checked at any time.

The error introduced by not correcting automatically for the superheat or wetness of the steam is small. A variation of 20 deg. fahr. in the superheat or 2 per cent in the wetness, corresponds to an error of about 1 per cent. Usually the superheat and the wetness are fairly constant, so that their variations can be allowed for by means of a table of corrective factors without introducing any material error.

It will be noticed, on reference to Fig. 9, that the meter body is full of water, and that two cooling chambers, CU and CD are provided. The function of these cooling chambers is to condense the steam which passes through the pressure noles on the upstream and downstream sides of the orifice. So long as the water level in these cooling chambers is *above* the horizontal center line on which the pressure holes are drilled, the true difference of pressure will be transmitted to the recorder. The portions of the cooling chambers below the level of the pressure holes provide reservoirs of water which prevent steam reaching the recorder when any air that may have separated in the pressure pipes is being blown away through the air vents V.

Valves U and D enable the meter to be shut off from the main, and the valve E enables the meter to be "equalized" (and the zero of the differential pressure pointer checked).

If the meters are overloaded, the corrugations of each pair of the diaphragms DP fit into one another, so that no damage is done. The meters are fitted with other protective devices (not shown in the diagram) which prevent them from being damaged if wrongly connected up, or if one pressure is turned on before the other. These protective devices have proved to be a most important feature of the meters.

The recorder referred to above and the orifice tipping are shown in considerable detail. This latter consists of an orifice plate fastened into a steel ring provided with a head through which the pressure holes are drilled, but no pressure holes have to be drilled in the pipe line. The coefficient of discharge of every orifice is determined by calibration with water. This has been found to be fully sufficient for most practical purposes, although where high precision is necessary, means illustrated and described in the original article must be used. The meter is not suitable for measuring pulsating flow unless the pulsations are reduced to a negligible amount at the point where the orifices are inserted.

The original article describes also a counter attachment which may be fitted to these meters. It is not described here as it does not differ materially from the fairly well-known integrating mechanism used in Kent water meters. (*South African Engineering*, vol. 32, no. 12, Dec. 31, 1921, pp. 243–245, 5 figs., *d*)

MOTOR-CAR ENGINEERING

Rickenbacker-Six Automobile, J. Edward Schipper. The new car incorporates some departures from usual engineering practice. For example, it has flywheels at the front and rear of the engine, which is claimed to minimize vibration. The cylinder block and the upper part of the crankcase are cast together, and the block casting is so designed that the chain case and the flywheel housing are bolted on, thus simplifying casting and machining processes.

The usual practice in finishing the connecting rods is to check the alignment of the rod on a gage, and if it is not true to bend the rod so that it will check properly on the gage. On the new car a small end of the connecting rod is ground to assure alignment, as was done by some of the manufacturers of aeroplane engines during the war. This alignment is important in eliminating side friction of the piston, insuring an easier- and smoother-running engine.

The clutch has a Raybestos facing, running in a bath of oil. It is claimed that the combination of this facing and the oil bath eliminates any possibility of burning and at the same time insures a smooth action. (*Automotive Industries*, vol. 45, no. 26, Dec. 29, 1921, pp. 1258–1261, 7 figs., *d*)

POWER GENERATION

Internal-Terrestrial Heat as an Important Source of Energy. Whether the theory of a molten central portion of the terrestrial globe is correct or not, there is no doubt that the temperature of the interior increases with the distance from the surface of the earth.

The observed increase amounts to about 3 deg. cent. for every 100 m. of depth, but there are reasons to believe that as the depth increases beyond a certain point the rate of increase in temperature becomes even greater than that. In any event, there is no question but what the temperature at some attainable distance from the surface is quite considerable, and the question is whether it might not be possible to utilize this heat commercially. The well-known scientist, de Moupertius, was the first who called attention to this possibility. In fact, partly on account of this and partly for solving many geological problems, he suggested to the Prussian Academy of Sciences in the middle of the 18th century that a shaft be dug to the center of the earth, a proposition which was vigorously ridiculed by his colleague in the membership of the Academy, the famous Voltaire.

The main obstacle in the way of commercial utilization of the internal heat of the earth is the thickness of the superficial layer over and above the sixth strata where sufficiently high temperatures obtain under the influence of the magma.

As a rule the surface layer is supposed to extend from 15 to 25 km. (10 to 16 miles). However, it is of uneven thickness and in some places, as, for example, near the hot springs in the Yellowstone Park and New Zealand, must be quite thin, possibly only a few hundred feet thick. In fact, in such places saturated steam comes naturally from the ground with temperatures of the range of 300 deg. cent. (572 deg. fahr.).

Of late Sir Charles Parsons has shown an interest in this problem. The question appears to be within technical possibility, but of quite uncertain economic practicability, at least under the conditions of today. (*Rauch und Staub*, vol. 12, no. 3, Dec., 1921, pp. 16–18, *g*)

POWER PLANTS (See Measuring Apparatus)

POWER-PLANT ENGINEERING (See Corrosion)

PRODUCER GAS AND GAS PRODUCERS (See Corrosion)

PUMPS

Operation in Parallel of Centrifugal Pumps and Fans

Operating Pumps or Fans in Parallel, J. C. Hobbs. Discussion of problems encountered in parallel operation of centrifugal pumps. Almost any properly designed fan or pump will perform satisfactorily if operated alone, but when two pumps discharge into the same distribution system operating in parallel certain requirements must be satisfied or trouble will occur. The situation is somewhat similar to the operation of electrical generators in parallel, and in order that fans or pumps operate properly they must have proper operating characteristics and the method of regulation must be correct. By characteristics is here meant the interrelations

between pressure produced, output, horsepower and speed, which may be expressed in the form of curves.

Figs. 10 and 11 show respectively the pressure characteristics that are favorable and unfavorable to operation in parallel. In Fig. 11 the characteristic curve, instead of being flat, has a hump, showing that there are two outputs having exactly the same pressure and speed. If two pumps with such characteristics are operated in parallel and discharge against the same pressure, one of them might be on the upward part of the curve and the other on the downward part, thus causing an unequal distribution of the load.

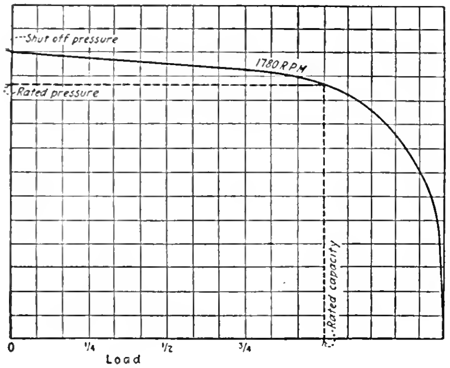

Fig. 10 Typical Pressure Characteristic of Fan or Pump Giving Satisfactory Operation in Parallel

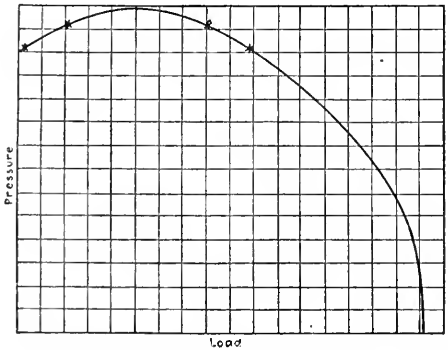

Fig. 11 Effect of Hump in Pressure Curve of Fan or Pump

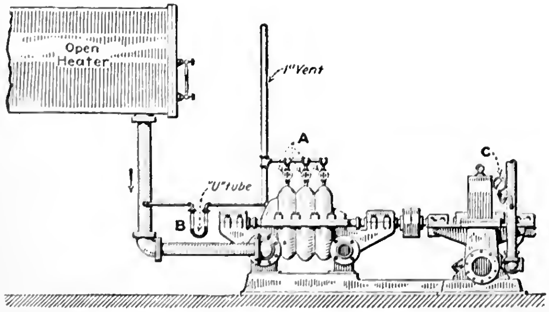

Fig. 12 Connections to Prevent Pumps from Becoming Steam- or Air-Bound

This condition is not so serious in cases in which steam-turbine drives are used, but with motor drives in which the speed is practically constant unsatisfactory performances will occur.

With a steam-turbine drive there is the possibility of one of the pumps being "backed off the line." When this occurs, there is danger of the pump becoming air-bound, and the rotor, in rubbing against the dry seal rings, will likely cause damage. Instances have occurred in which parts of the bronze impellers and seal rings have melted, owing to the large input of power from the turbine shaft being converted into heat through friction.

It is not desirable to try to regulate the pressure between excessively narrow limits, because hunting action of the governor and pressure-control valve may occur. The desirable form of characteristic is one in which the discharge pressure drops slowly from zero load up to a point beyond the full capacity rating, and then drops off suddenly.

The possibility of damage to a pump on account of becoming steam- or air-bound has been reduced, if not eliminated, by provisions indicated in Fig. 12. This shows a scheme of piping which can be used in connection with open heaters to prevent the first stage from becoming steambound. The arrangement should be installed on each pump operated in parallel, whether it has the proper characteristics or not, because a small amount of trouble with the pressure governor is liable to divide the load unequally at any time, and one of the pumps may cease to discharge water when the total load becomes light.

A metering arrangement on the discharge of the pump is desirable, such, for example, as the U-tube in Fig. 12, which is installed in such a way to use the friction head through the suction piping for approximately indicating the flow. Such a meter does not measure the exact quantities flowing, but shows relatively the load on the different pumps.

The original article discusses in some detail the effect of using different shapes of impeller blades. (*Power*, vol. 55, no. 2, Jan. 10, 1922, pp. 58-60, 6 figs., *p*)

The "Hydrohoist" Endless-Rope Pump. Description of a novel variation of the endless-rope pump made by a British concern. In this pump an endless flexible wire rope is used having threaded on it a series of small pressed-steel cups, both the rope and the cups being galvanized. Each bucket or cup is made in the press and is fitted in the center with a pressed thimble which acts as a spacing piece and through which the flexible rope is threaded. The standard size of the cups is $1^1/_2$ in. in diameter and the rope works over pulleys 14 in. in diameter.

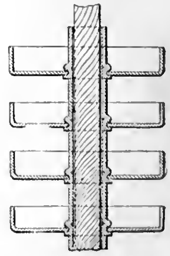

Fig. 13 "Hydrohoist" Endless-Rope Pump

The manufacturers state that with an immersion of 3 ft. and rope speed of 600 ft. per min. the delivery is 3500 gal. per hr. This is due to the fact that not only are the buckets completely filled with water, but in addition a large quantity of it is carried upon the outside. The pump can be worked by hand on lifts as high as 150 ft. (*Engineering*, vol. 112, no. 2918, Dec. 2, 1921, p. 759, 1 fig., *d*)

RAILROAD ENGINEERING

Wheels for Railway Rolling Stock. Description of a new process for producing disk-center wheels developed in England in 1921 and carried on at Coventry by Powell, Brett, Ltd. The process consists in turning out wheel centers in the shape of drop forgings by means of special hammers.

The wheel centers are produced direct from an ingot by a special process, and the cast condition of the steel under powerful drop hammers is broken down into a proper forged state. The final operation of stamping ceases practically at the critical period of temperature of the steel, and the center leaves the dies with the material in what is said to be an ideal state, uniform in shape, perfectly balanced, and possessing a ductility and tensile strength leaving nothing to be desired for this class of steel.

No more information is given as to the process of manufacture, but some data of tests are published. It is said, however, that the production of wheel centers by this method involves the employment of a very powerful drop hammer of special design. The tup

and dies used in the final operation are shown in one of the illustrations. (*The Railway Gazette*, vol. 35, no. 27, Dec. 30, 1921, pp. 1000–1002, 6 figs., *d*)

Gasoline-Driven Rail Car. Description of a car manufactured by the J. G. Brill Co., on a chassis made by the International Motor Co., and in design following essentially the Mack automobile truck. The car has seating capacity for 31 passengers, operating speeds up to 30 m.p.h., and weighs about 11,000 lb.

The Gilmore & Pittsburgh R. R. has recently placed one of these cars in service, but having space for the accommodation of baggage and seating 17 passengers. The railroad runs from Armstead, Mont., to places in Idaho through a mining country with severe grades as high as 6 per cent. The snows in that section of the country are so severe that at times it is impossible to operate steam trains for a week or ten days at a time, but except in the worst snow the car has been able to operate successfully.

Another instance of the operation of a gasoline rail car having proved an effective means of stimulating passenger traffic and curtailing operating costs, is provided in the case of the Narragansett Pier Railroad Co., in Rhode Island. This railroad is eight miles long and had the competition not only of automobiles but until recently of an electric line (abandoned in Nov., 1920).

The comparison of operating costs of light steam trains and gasoline rail cars in local passenger service shows that the cost per mile on a steam train is \$0.95, as compared with \$0.14 to \$1.21 for the gasoline car. In one instance the cost was \$1.56 for the steam train and \$0.25 to \$0.38 for the gasoline car.

The company has also designed a larger car, to seat 35 passengers in addition to the baggage space.

Comparisons of cost per seat per mile between the steam train and gasoline car show a striking difference in favor of the latter, often exceeding 50 per cent. (*Railway Review*, vol. 69, no. 26, Dec. 24, 1921, pp. 860–863, 4 figs., *dcp*)

Sandberg Sorbitic Steel

Sandberg Sorbitic Steel for Tires. References have occurred in the engineering press to Sandberg sorbitic steel, and tests are being carried on in this country on rails made of this material. On account of this, the information contained in the present abstract may be of interest. As known from the general metallurgy of steel, the microstructure and physical properties of steel depend on its rate of cooling. Slow cooling produces pearlitic condition, with softness and ductility. Sudden cooling from a temperature above the upper critical point produces martensitic conditions, and makes the steel intensely hard and correspondingly brittle. Sorbite is softer and tougher than martensite and harder than pearlite, and is obtained by a slower rate of cooling than that used to produce martensite but not slow enough to create the pearlitic condition.

The method used in the Sandberg process consists of heating the steel to a temperature above the critical point, and then cooling it so slowly that the martensitic condition is not retained and yet the cooling is sufficiently rapid to offset the pearlitic stage being reached. The cooling is done by blowing air or steam on the heated steel. In making tires for railroad wheels they are cooled by being placed one at a time on a revolving table. Moist air is then drawn through branch pipes and nozzles on to the tread of the tire.

The results given in Fig. 14 refer to a test of railroad-wheel tires, all from the same cast of steel. The third line refers to tires cooled in the atmosphere but not reheated. The railroad tires were 2 ft. $9^{1}/_{2}$ in. internal diameter and of a section $5^{5}/_{8}$ in. wide and $3^{3}/_{8}$ in. deep in the middle of the tread.

The original article contains microphotographs showing very clearly the difference in structure between the treated and untreated steel. The steel in these tires contained 0.73 carbon, 0.313 silicon and 0.74 manganese. The process is said to have been successfully applied also to steels of lower carbon content. (*The Railway Gazette*, vol. 35, no. 27, Dec. 30, 1921, pp. 991–993, and 999, 6 figs., *cd*)

SPECIAL PROCESSES (See also Railroad Engineering)

Gear Manufacture by Upsetting. At the new shop of the Amforge Company recently completed at Chicago a method was developed for the production of gear parts which it is claimed gives a stronger product than hammer forging.

In making these gears round bar steel of forging quality is used after close inspection for seamy stock. The bar is always forged horizontally and forced into the dies by the headers in two or three operations. In the finished pinion the grain of the steel is such that teeth will be cut against it. As a further advantage for the upsetting method of gear manufacture, it is claimed that it does not tend to crystallize the steel as drop forging is apt to do at times.

It may be mentioned in this connection that the process of upset forging is practically in its infancy, the plant of the Amforge Company being the only one in the world devoted exclusively to the manufacture of upset forgings. This new method has been developed only within the last few years, but this development has been so rapid that it is estimated that 250 upset-forging machines are now operating on commercial forgings. (*The Iron Age*, vol. 109, no. 6, Feb. 9, 1922, pp. 401–404, 5 figs., *d*)

STEAM ENGINEERING (See Measuring Apparatus)

TESTING AND MEASUREMENTS (See also Measuring Apparatus)

Measurement of Pulsating Flow by Nozzles

The Use of Nozzles in Measuring Pulsating Flow. When nozzles are used for measuring pulsating flow, errors result unless the flow curve is known as a function of time. In the testing or regular supervision of the air delivery of reciprocating compressors, it is quite possible to install a large tank between the compressor

and the delivery line. This tank may well act as an aftercooler for removing the moisture from the air. If this tank be about three or four times the volume of the high-pressure cylinder, the flow fluctuations are greatly reduced. If in addition a throttling flange be applied at the end of the tank, i.e., at the place where the tank joins the delivery pipe—then the flow in the delivery pipe will be rendered quite even, and a nozzle or a similar instrument can be used with great accuracy. The larger the tank and the smaller the throttling flange, the more uniform is the flow. The flange need not be so small as to produce any noticeable pressure drop.

The same method can also be used in the application of steam meters to measure the flow of steam for reciprocating engines. Every engine should be equipped with a large receiver separator, and can in addition be equipped with a throttle flange at the place where the steam main joins the receiver separator. The flow is made even enough to apply a steam meter and to accept its readings without any correction.

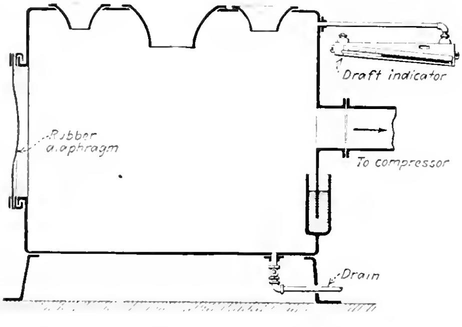

Fig. 15 Use of Nozzle on Inlet Side of Compressor

It has also been suggested that the flow in lines carrying variable-velocity fluids can be made even for a distance by placing a fan in the line at either side of the nozzle or of the measuring instrument. The theory is that the fans have inertia and resist pulsating flow, thereby reducing the violence of the pulsations.

For the ordinary run of shop compressors, it is usually preferable to test the compressor while in operation. This can be done by using nozzles on the inlet side, provided, of course, that the piston-rod packings are tight. In this case it is quite easy to obtain uniform flow by attaching to the compressor inlet a sheet-iron box which carries the nozzle or nozzles, and which in addition is equipped with a rubber diaphragm as shown in Fig. 15. The volume of the box acts as an equalizer, and the rubber diaphragm which flops in and out helps materially to maintain an almost constant flow through the nozzles. A box of this kind is a very valuable adjunct to mechanical laboratories and especially to shops in which air compressors are built or used, because it allows testing of the actual air-compressor delivery with very little trouble. To this end it is advisable to have several nozzles in the box and to plug up those not in use.

It is very desirable to have a safety valve on the box to protect the rubber diaphragm from injury in case some one should close more nozzles than is good for the rubber. Such a safety valve is indicated on the right-hand side of the box in the shape of a U-tube full of water. The section of the U-tube must be large enough to prevent the formation of such a vacuum in the box as might break the rubber diaphragm. The pressure drop of the nozzles can be kept quite small, and can be measured by means of an inclined gage, such as a draft gage. The pressure drop through the nozzles amounts to much less than the variation in barometric pressure, and no fear need exist that the measuring box will interfere in any way with the air delivery of the compressor.

Nozzles have not been used for testing to the extent they deserve, probably because of lack of standard nozzles on the market. However, these are now available. Occasionally it is practically impossible to dampen the vibrations on account of the size of the equipment—for instance, to the air inlet of blast-furnace blowing engines. In that case the flow-velocity curve can be determined occasionally by placing in the nozzle a very light flapper and by recording its motion on the indicator. (*Chemical and Metallurgical Engineering*, vol. 26, no. 1, Jan. 4, 1922, pp. 32–34, 3 figs., *dp*)

Chemical Research in Germany. In connection with the story of the development of a process for the manufacture of synthetic gold in Germany, given wide circulation by the public utterances of Prof. Irving Fisher, *The Chemical Age* quotes the information of authorities who have made personal inquiry into the matter that important progress has been made during and since the war in agricultural chemistry in Germany.

It is said that processes have been developed of treating seed both to protect it from pests and disease, and to increase its vigor enormously. The idea, in short, has been by new chemical processes of fertilization to impregnate the seed with energy which has hitherto been applied externally at later stages of growth. How far this is true we are not in a position to say, but it is confidently asserted that as the result of experiments, seed so treated is rendered far more immune from disease and pests, that the plant life is fed with far greater effect and becomes proportionately more vigorous, and that the yield is largely increased. All this, like the story of synthetic gold, has to be proved in practice, but it is enough to convince us that German research chemists, instead of resting content with past achievements, are working for further advances and eagerly searching after new starting points. (*The Chemical Age*, vol. 5, no. 132, Dec. 24, 1921, p. 788, *g*)

Wages in German Machine Industries. Table 1 shows a comparison of hourly wages paid in the machine-building industry in Chemnitz, Germany, previous to the war and since Jan. 1, 1922. In the present agreement on wages of workers in the metal industries a basic hourly rate is fixed, and the worker receives a certain additional rate on account of the high cost of living. In the table these two items are added together. Furthermore, skilled workmen who are always employed at an hourly rate (not on piece work) receive an additional amount which has also been included in the figures given. In figuring present exchange, one mark has been assumed to be equal to 0.6 cent. (*Machinery*, vol. 28, no. 6, Feb., 1922, p. 453, *g*)

Overhead Conveyances. A new type of overhead conveying system has been placed on the market and it is claimed that its construction is such as to make it necessary to erect a superstructure from which to suspend the system. The track consists of two parallel rails which is said to minimize the possibility of the trolley jumping the track. The rails are laid on a plate to which the U-bolt hangars are bolted and are thus supported from the bottom instead of the top which is said to eliminate the danger of the rails becoming dislodged and dropping to the floor. To insure further the stability of the track a special rail section is used with the base wider on one side than on the other. By throwing the center of gravity of each rail towards the middle of the track, the possibility of the rails being forced out of position and turning outward is reduced. (*The Iron Age*, vol. 109, no. 6, Feb. 9, 1922, pp. 409–410, 5 figs., *md*)

CLASSIFICATION OF ARTICLES

Articles appearing in the Survey are classified as *c* comparative; *d* descriptive; *e* experimental; *g* general; *h* historical; *m* mathematical; *p* practical; *s* statistical; *t* theoretical. Articles of especial merit are rated *A* by the reviewer. Opinions expressed are those of the reviewer, not of the Society.

ENGINEERING RESEARCH

A Department Conducted by the Research Committee of the A.S.M.E.

Research Résumé of the Month

A—Research Results

The purpose of this section of Engineering Research is to give the origin of research information which has been completed, to give a resume of research results with formulas or curves where such may be readily given, and to report results of non-extensive researches which in the opinion of the investigators do not warrant a paper.

Electrical Instruments A1-22. Capacity Effects in Induction Coils. A coil of wire wound in any of the familiar forms called *inductance coils* behaves in an electric circuit primarily as an inductance. The potentials of the different parts of the coil are, however, different from each other and from the potential of the ground. For this reason the coil also behaves to a certain extent as an electric condenser, or rather a system of condensers. These capacity effects of inductance coils are particularly important at the high frequencies employed in radio communication. The effective capacity of an inductance coil depends in general both on the capacities existing between parts of the coil itself and on the capacities existing between parts of the coil and the ground.

On account of the importance in radio communication of capacity effects in inductance coils, careful studies of these effects, both theoretical and experimental have been made at the Bureau of Standards. An interesting result which has been found is that one effect seems to depend primarily on the capacity of the coil to ground. This effect is observed when two condensers in series are connected across the terminals of the inductance coil, and the common terminal of the two condensers is grounded. If the inductance coil possesses capacity to ground, the familiar criterion for resonance in the system, computed from the known value of the capacities of the two condensers, will not apply.

If both condensers are variable and the system is adjusted for resonance by successively assigning arbitrary values for the setting of one condenser and then tuning with the other condenser, it would be expected from elementary considerations, neglecting the effects of distributed capacity, that the successive resonance values of the capacity of the two condensers in series, determined as the product of their capacities divided by their sum, would be constant. On account of the distributed capacities this simple relation does not hold. It is found, however, that under the conditions above mentioned, with the common terminal grounded, the capacity of the two condensers in series determined as the product of their capacities divided by their sum, is linearly related to the reciprocal of the sum of their capacities. This relation has been verified both mathematically and experimentally.

The results of both the mathematical and experimental investigation of this particular phase of the problem of capacity effects in inductance coils are given in Scientific Paper No. 427, entitled "Some Effects of the Distributed Capacity between Inductance Coils and the Ground," which has just been issued by the Bureau of Standards. Copies may be purchased from the Superintendent of Documents at 5 cents a copy.

Fuels, Gas, Tar and Coke A5-22. Lignite Carbonization. One of the recent reports of the Bureau of Mines is that on Lignite Carbonization and Carbonized Residue Briquets by W. W. Odell, Fuel Engineer. In his introduction the author states that "the development and utilization of low-grade fuels is not new, but on this continent conditions have not heretofore been favorable to such enterprises. The abundance of the available supply of lignite in this country in locations where other fuel is only obtainable by a long freight haul from distant sources, has made the 'lignite problem' a serious one for domestic consumers in such localities as North and South Dakota and Texas."

The plan of the work was to carbonize approximately 1000 tons of raw lignite by continuous operation of the carbonizer, briquetting the residue into a firm, solid fuel, and to obtain meanwhile as much data as possible relating to the following: (1) Quality and quantity of gas obtained, (2) quantity of gas required for carbonizing, (3) behavior of lignite during processing, (4) capacity of carbonizer, (5) quality and quantity of residue obtained under various conditions, (6) analyses of lignite, residue and the briquets made therefrom, (7) binder requisites, (8) character of briquets made, (9) control methods, (10) cost of briquetted residue, (11) quantity of by-products, and (12) design of apparatus suitable for carbonizing lignite. Address Bureau of Mines, Washington, D. C., H. Foster Bain, Director.

Fuels, Gas, Tar and Coke A7-22. Alcohol for Power. The Fuel Research Board of the British Department of Scientific and Industrial Research have prepared for distribution the Second Memorandum on Fuel for Motor Transport. This report gives a brief general survey of the work of the Fuel Research Board with regard to Power Alcohol since July, 1920, the date of the publication by H. M. Stationery Office of the Board's Interim Memorandum on Fuel for Motor Transport."

The subject is dealt with under the following heads: (*a*) Raw Materials, (*b*) Experimental Cultivation of Jerusalem Artichokes and Sugar Mangolds, (*c*) Molasses as a Raw Material, (*d*) Production of Alcohol in the British Dominions and Colonies, (*e*) Synthetic Production, (*f*) Production from Cellulosic Materials, (*g*) Legislation, (*h*) Denaturing, (*i*) Experimental Work on Utilization, (*j*) General Conclusions. Address H. M. Stationery Office, 28 Abingdon Street, London, S. W. 1. Price including postage 7$^1/_2$d.

Gases, General A1-22. Gas Cylinders. The British Department of Scientific and Industrial Research has just issued the first report of its Gas Cylinders Research Committee. This report, which consists of a majority and a minority report, gives the conclusions and recommendations of the Gas Cylinders Research Committee on the types of gas cylinders which should be employed for the storage and transport of compressed gases which are not in the liquid state in the cylinder.

Appendices to the Report include full reports on tests made at the National Physical Laboratory on cylinders of high-carbon steel subjected to varying heat treatments and on very light steel cylinders made for the Royal Air Force during the war, a summary of the evidence given by witnesses before the Committee, a summary of the regulations governing the use and transport of cylinders in Great Britain, France, Germany, and the United States of America, and a note on the deviations of technical gases from Boyle's Law. Address H. M. Stationery Office, 28 Abingdon Street, London, S. W. 1. Price including postage 7s. 9d.

Heat A2-22. Thermal Stresses in Steel Car Wheels. For some time the Bureau of Standards has been accumulating data obtained in thermal tests of car wheels. So far the tests on 16 wheels have been completed and it is possible to summarize the interesting features of this data as follows:

1 None of the steel wheels failed.

2 Because of the movement of the hub with respect to the rim, on account of the heating of the rim, a beam effect is produced in the plate which induces tensional stresses near the hub and stresses in compression near the rim on the face of the plate, while on the back of the plate the stresses are approximately equal in magnitude but reverse in nature.

3 These effects were observed in new wheels, while in the case of old wheels the stresses on the face of the plate were in tension near the hub and at the rim they decrease to practically nothing, this difference from the new wheel probably being due to the quantity of metal worn away.

4 The magnitude of the maximum stresses developed approximated the yield point of the material as determined in tensile tests.

5 After the first "run" on the new wheels, an apparent set was obtained which was not the case in succeeding "runs" nor in "runs" on old wheels. The maximum stresses were in the surface of the plates and beyond the yield point of the material.

Further work on single-plate chilled-iron wheels seems justified in view of the fact that a survey of the stresses on the back of the plate of this type of wheel was not made. From experience with the steel wheels, it is believed that the stresses will be quite different from those on the face. Address Dr. S. W. Stratton, Director, Bureau of Standards, Washington, D. C.

Lignite A1-22. Lignite Carbonization. See *Fuels, Gas, Tar and Coke A5-22.*

Petroleum, Asphalt and Wood Products A2-22. Specific Heats and Heats of Vaporization of Motor Fuels. In a paper read before the American Chemical Society Messrs. Robert E. Wilson and D. P. Barnard, 4th, present the results of a series of observations on the total sensible heats of completely vaporized motor fuels. These, combined with critically compiled data from the literature on heats of vaporization of motor fuels, make it possible to draw accurate total-heat curves over the whole range of temperatures up to 500 deg. cent. and derive fairly accurate values for the specific heats of the hydrocarbon vapors. Combinations of these with vapor-pressure data make it possible to determine just how hot the air or the fuel must be preheated in order to completely vaporize the motor fuel in a carburetor. Address Charles L. Parsons, Secretary, American Chemical Society, P. O. Box 1505, Washington, D. C.

B—Research in Progress

The purpose of this section of Engineering Research is to bring together those who are working on the same problem for cooperation or conference, to prevent unnecessary duplication of work and to inform the profession of the investigators who are engaged upon research problems. The addresses of these investigators are given for the purpose of correspondence.

Electric Power B1-22. Design of Electrical Machinery and Lines. During the present year Prof. V. Karapetoff is carrying on an investigation on mechanical aids in the design of electrical machinery and lines. He expects also to make a study of fields of force or flow, electric,

magnetic and hydraulic. Address Professor Karapetoff at Cornell University, Ithaca, New York.

Highways B1-22. Traction Dynamometer. See *Transportation B1-22.*

Machine Tools B1-22. Cutting Tests of High-Speed Tool-Steel Bits. See *Steel, Its Treatment and Products B1-22.*

Steel, Its Treatment and Products B1-22. Cutting Tests of High-Speed Tool-Steel Bits. A number of tool bits of standard high-speed tool steel have been heat-treated in various ways by the Bureau of Standards to determine the effect of these treatments on the cutting qualities of the metal. About 55 cutting tests were made, and while no new facts were brought to light, the data obtained were interesting and show that it is possible to obtain valuable results from tests made with such small samples. This work is being continued, and an effort will be made to study the time temperature relations in preheating and hardening on the cutting qualities of high-speed tool steels. Address Dr. S. W. Stratton, Director, Bureau of Standards, Washington, D. C.

Transportation B1-22. Traction Dynamometer. Prof. F. L. Fairbanks is now developing and completing at Cornell University a traction dynamometer of considerable interest.

Ventilation B1-22. Infiltration of Air. A study of the infiltration of air into buildings through walls and windows is one of three problems which Prof. H. Diederichs has taken up this year. The other two are (*a*) satisfactory heat treatment of "Kimite" alloy steel and (*b*) the combustion process in a Diesel engine.

D—Research Equipment

The purpose of this section of Engineering Research is to give in concise form notes regarding the equipment of laboratories for mutual information and for the purpose of informing the profession of the equipment in various laboratories.

Available Equipment. In a letter just received from Assoc. Prof. William J. Dana of the Mechanical Engineering Department of North Carolina State College of Agriculture and Engineering, it is stated that owing probably to its distance from a large industrial center the facilities of the mechanical laboratory of this college, though well equipped, are not being taken advantage of. They have all the usual small apparatus, such as the Emerson bomb calorimeter, the Saybolt viscosimeter, the Sargent improved gas calorimeter, etc. Their power plant and equipment include six boilers, hand-fired, steam engines, small steam turbines, an 11-hp. Foos engine and other gas and oil engines of various sizes.

F—Bibliographies

The purpose of this section of Engineering Research is to inform the profession of bibliographies which have been prepared. In general this work is done at the expense of the Society. Extensive bibliographies require the approval of the Research Committee. All bibliographies are loaned for a period of one month only. Additional copies are available, however, for periods of two weeks to members of the A.S.M.E. These bibliographies are on file at the office of the Society.

Petroleum and Allied Substances. Under the title Recent Articles on Petroleum and Allied Substances, Mr. E. H. Burroughs, Bibliographer of the Bureau of Mines, has compiled a valuable bibliography of interest to all those in any way connected with the petroleum industry. This report is known by Serial No. 2305 and may be obtained by addressing H. Foster Bain, Director, Bureau of Mines, Washington, D. C.

CORRESPONDENCE

CONTRIBUTIONS to the Correspondence Department of Mechanical Engineering are solicited. Contributions particularly welcomed are discussions of papers published in this Journal, and brief articles of current interest to mechanical engineers.

Advantage of Nitrogen in the Boiler Furnace

To the Editor:

Referring to the short article on the Advantage of Nitrogen in Boiler Furnaces, published on page 802 of the December issue of Mechanical Engineering and credited to *Power,* I would say that the logic of it is all wrong. To carry the author's course of reasoning further, why not run with large quantities of excess air and buy coal with the largest possible amount of ash so as to lower the furnace temperatures to the greatest possible extent?

The use of oxygen or enriched air promises paying results in blast furnaces or open hearths, etc., because the working temperature of the furnace is so high that normally most of the heat generated passes off in the products of combustion, and any method by which the volume of these and their heat control may be materially reduced will have an enormous effect on the efficiency and fuel consumption of these furnaces. Boilers, on the other hand, can utilize heat down to very low temperatures by the use of economizers so that the possible fuel saving is much less, and the cost and complication of the apparatus for supplying oxygen would have to be reduced correspondingly to make it commercially attractive.

From a purely operating point of view, however, the problem of boiler adaptation is simpler than maintaining a roof in an open hearth at any higher than present temperatures, though these can be controlled and practically the same efficiency of the process obtained by arranging the mixture of fuel and oxygen so that this and the combustion are progressive and the heat is absorbed as fast as it is generated, resulting in temperatures not exceeding a safe limit but with all the heat generated at a high enough temperature to be effective.

I have seen a boiler with a little over 10,000 sq. ft. of heating surface evaporate over 150,000 lb. of water per hour for 3 hours on oil fuel, so that no anxiety need be felt regarding the heat absorption of the water-cooled surfaces.

Material arguments controverting those in the article in question appeared over the writer's signature in the issue of *Power* for November 22, 1921.

New Haven, Conn. H. D. Fisher.

Novel Pumping Plant in Operation at Key Biscayne, Florida

To the Editor:

A rather unique pumping plant has been placed in operation at Key Biscayne, Miami, Florida. The accompanying snap shots show the installation of an overshot water wheel to take the flow from an artesian well. This wheel, 12 feet in diameter and turning at 7 r.p.m., is geared to a duplex pump operating at 40 strokes per minute which is used to pump water from the well drainage sump well into an elevated storage tank. This tank supplies water for irrigating a nursery and also for homes on the island.

Overshot Wheel Driving Duplex Pump

The water from the well is very strong in sulphur and comes from a depth of approximately 1,000 feet. Tests give the rate of flow at an elevation of 12.92 feet as 248 gallons per minute which provides 0.82 hp. for operating the wheel. 0.46 hp. is utilized in pumping the water which gives an overall efficiency on the plant of 56.8 per cent.

Welton A. Snow.

Miami, Florida.

Standardization in Japan and Norway

Standardization work in Japan has recently been given a great impetus by the organization of the Japanese Engineering Standards Committee. The main function of this Committee is to serve as a bureau for solving and initiating problems involving engineering standardization. The Committee consists of 70 members presided over by the Minister of the Department of Agriculture and Commerce acting as president, and a vice-president, who is elected or appointed. The details of the work are handled by seven secretaries who are engineers of the government departments of Agriculture and Commerce, Communications, Railways, Military Engineers and Naval Engineers. The work is being pushed with vigor, investigations already being under way on metals, woods, bricks, screws, electric wires and electric motors.

In Norway a national standardization committee has been organized by the Federation of Norwegian Industries. One of the first projects which is being taken up by the new committee, after the necessary work on organizational problems, is the standardization of ship machinery and ship details.

There are now national standardizing bodies in the following fourteen countries: Austria, Belgium, Canada, Czechoslovakia, France, Germany, Great Britain, Holland, Italy, Japan, Norway, Sweden, Switzerland and the United States.

International Cooperation in Standardization

A.E.S.C. Sales Agent for Foreign Standards. The American Engineering Committee has just completed arrangements by which coöperation with the standardizing bodies in other countries will be made more effective. In doing this it has followed out the recommendations of the Unofficial Conference of the Secretaries of the National Standardizing Bodies held in London in April, 1921.

In order that all standards shall be available to the industries of the various countries, it is planned that each national body will sell the approved standards of the other bodies. The American Engineering Standards Committee, 29 West 39th St., New York City, has available now the publications of the standardizing bodies in Austria, Belgium, Canada, France, Germany, Great Britain, Holland, Sweden and Switzerland.

Hereafter the A.E.S.C. will regularly exchange information with the foreign bodies as to the status of work on the various projects being undertaken under its auspices. This information will be limited to the indication of the stage of development of the projects, it being left in each case to the various sectional committees and sponsor bodies to decide to what extent they desire to exchange technical memoranda or drafts of standards. This exchange of information on the general progress of the work will, however, lay the basis for closer international coöperation as the need for this develops in special instances.

A.S.M.E. Transactions Index Contemplated

Pressure has been exerted on the Society to compile and issue a comprehensive index of Transactions to date. Such a book will render available the exceedingly valuable information contained in Transactions, and the Committee on Publication and Papers has the project under advisement, pending an expression of opinion from the Society. The acknowledgment card, which is sent out with volume forty-two of Transactions, will permit a statement of each member's desires in the matter of this index, and if sufficient orders are received the book will be issued some time during the fall. It will be bound in half morocco, uniform with Transactions. Price will depend somewhat on the number of copies ordered, but it is believed that it will not exceed $4.00.

A Correction in Machine-Shop Discussion

Professor John Airey has called our attention to an error in the report of his closure to the discussion on the paper entitled Art of Milling by John Airey and Carl I. Oxford. At the bottom of page 16 of the January issue of Mechanical Engineering mention is made of "machine belt." This should have read "machine ability tests." The shortness of time alloted to the discussion of this paper did not permit a proper closure by Professor Airey. This will be included in Transactions.

STANDARDIZATION, AMERICAN INDUSTRY AND THE FEDERAL GOVERNMENT

(*Continued from page 180*)

not to deal with technical details has proved a source of great strength in its real work of insuring the full coöperation of organizations producing standards not in conflict.

An Example of Functioning of the A.E.S.C.

In determining the desirability of undertaking the development of a proposed standard, it has proved highly satisfactory to initiate the movement by calling a conference of the bodies interested, which the A.E.S.C. does upon request from a responsible organization or organizations.

As an example of such a conference, mention may well be made of the Conference on the Standardization of Railroad Ties held in Washington, D. C., in October, 1921, at the joint request of the Forest Service and the American Railway Engineering Association. Invitations to this Conference were issued to the several national organizations representing not only producers and consumers but also general interests, the last mentioned being the American Society of Civil Engineers, the American Society for Testing Materials, the Department of Commerce, and the Forest Service. The official representatives of the organizations were asked to decide: (1) whether the unification of specifications for railway cross-ties and switch ties should be undertaken; (2) if so, what the scope of the work should be; and (3) how the work should be organized.

After a very full discussion of all phases of the important problem before it, this Conference reached a unanimous agreement on all points under consideration. It recommended that the Forest Service and the A.E.R.A. be designated as joint sponsors for a "Sectional Committee" to unify railway-tie specifications under the Rules of Procedure and auspices of the A.E.S.C., and recommended to the sponsors that certain specified national organizations be invited to be represented officially on the sectional committee. Although it might seem apparent, without discussion, that the unification of railway-tie specifications should be undertaken, the subject was discussed for two hours before the Conference was asked to place itself on record on this matter, which it did by unanimous vote. All of this discussion was beneficial in paving the way for the discussion of the scope of the work and the organization therefor.

A conference called as this conference was called and conducted as this conference was conducted results in a spirit of coöperation that cannot otherwise be brought into existence. The plans laid down for carrying out the work of standardization will insure that the coöperative spirit brought into being by the conference will continue to be the controlling feature of the work of eliminating existing conflicting standards and "Americanizing" the standards that will be formulated hereafter.

Too much emphasis cannot be put upon the advantages of the conference method of initiating work on any particular standard or set of standards, provided the conference is truly representative. When men get together in such a conference, from an interchange of ideas they obtain a comprehensive view of the whole field; harmony emerges from discord and differences disappear in agreement.

Advantages of National Standardization Reiterated

In closing, it cannot be too often repeated that a national standardization program means almost unlimited advantage to the manufacturer in cheapening the processes of production and stabilizing his market; to the distributor in clarifying and simplifying his problems; and to the ultimate consumer by lessening costs and expediting deliveries. The real significance of standardization to industry and the Federal Government—what it may mean and what it can accomplish, will not be fully realized until there is sincere coöperation which is sympathetic, systematic and comprehensive, between industry and the Federal Government, in which coöperation the general consumer has a part.

Contributions of interest to the profession are solicited. Communications should be addressed to the Editor.

Engineering Education—the Development of the Resourceful Mind

It may seem presumptuous for me to offer any observations upon the subject of engineering education. I feel prompted, however, to make the attempt, at least, because of the kindly urgent request of the Editor of this magazine and also because the end of education for the engineer is the same as for any other profession. This end in a word is the development of mind and of character. One who has a highly developed mental equipment without character is a menace to the community; one who has character without mind, however high may be his purpose and ambition, proves ineffectual in the contests and conflicts of life. Therefore, I affirm most emphatically that true education has for its object both the trained mind and the thoroughly trustworthy character.

John Grier Hibben

Owing to the limits of the space assigned me I shall confine my observations solely to the training of the mind, not wishing however, to leave the impression that I regard character as in any way of secondary significance.

The discipline of the mind depends more upon the methods of teaching than the subjects taught. In preparing for the career of an engineer, as for any other profession, it is indispensable for future success and conspicuous leadership that the student should be led to a firm grasping of fundamental principles rather than the mere accumulation of facts. The fundamental sciences, mathematics, physics and chemistry, must be mastered by every student of engineering. To acquire a knowledge of these sciences encyclopedic information is not adequate.

Many centuries ago Aristotle remarked that there are two types of mind, the one which acquaints itself with the facts of a subject, and the other which penetrates to the reasons underlying these facts. The latter, he adds, are the philosophic minds. By philosophic mind Aristotle meant what we today would characterize as the scientific mind.

The true engineer must be the scientific engineer, that is, the one acquainted with the great fundamental principles of the underlying sciences of his profession and who early acquires the habit of asking the question Why, and searching for the answer with eagerness of spirit as for a hidden treasure.

Many years ago one of our graduates in engineering started a career in the West of very brilliant promise, brought to an end with only partial achievement by a fatal accident in the prosecution of his duties. Upon one occasion I met him in Princeton and I asked him what in his opinion was the most valuable characteristic of a successful engineer. After a moment's thought he responded, "The most successful engineer is the man who does not lose his head when face to face with an entirely novel situation." This gives the gist of the whole matter. To learn a rule easily applicable to familiar conditions and to apply the same with facility calls for a mind of intelligence, of course, but one acting only on the low level of routine. But to encounter a problem not familiar because disguised by entirely new conditions, to penetrate to the heart of the difficulty, to seize upon the possibility of applying some fundamental principle of mechanics, or of mathematical law, and to devise a method of procedure which will attain the desired result, this requires the talent of the truly scientific mind.

Throughout the whole of the training of the engineer there must be the supreme objective held in view by the teacher and by the student alike, namely, the development of the resourceful mind. That is the reason why I feel that an engineering education should produce first of all the engineer as such, rather than the engineer in any particular phase of his profession, such as that of the civil, the mechanical, the electrical, the chemical or the mining engineer. I imagine that the difficult problems which come to the engineer, however highly specialized his work may be, can never be dealt with satisfactorily by a knowledge only of his specialty. A problem in mechanical engineering may require the mechanical engineer to make his excursion into neighboring fields for the solution of the problem.

No method in education moreover, is satisfactory which appeals solely, or in a large measure, to the memory. The point of attack must always be the reasoning powers of the student, not only that, but there must be in the schedule of his studies and in the method of teaching a constant stimulation also of his powers of imagination. I do not refer to the unlicensed ranging of his fancy in fields foreign to his subject, but I do insist upon the mind being quickened in the solution of any problem by the discernment of all the possibilities of solution which may be dictated by the reason. We often think that the function and scope of the imagination are the natural activities solely of the artistic temperment, but there is a type of imagination which is essentially the function of the reasoning powers of man.

When an unfamiliar situation develops in any engineering enterprise and which stands as a stubborn obstacle in the way of progress it is the mind possessing imaginative skill which immediately brings before its scrutiny the complete array of possibilities of explaining the fundamental reason for the obstacle in question, and that in itself suggesting a proper method of overcoming it.

There is another phase in the career of the engineer which he has in common with all men whose work is to possess some permanent value for his day and generation. He must be able to deal successfully with the human elements in his problem as well as the material.

General Goethals said of his great engineering enterprise in Panama, that the great difficulty of his work was the human problem. There must be, therefore, in the engineering studies not only the laying deep of the foundations of the fundamental principles of the great sciences, but there must be a like fundamental knowledge of human nature in its manifestations, both of the past and of the present.

I appreciate the fact that the secret of dealing wisely with men, gaining their confidence, understanding their weakness and their strength, creating among them a spirit of coöperation and even of willing sacrifice—all these are essential to the success of an engineer and cannot be adequately learned from textbooks or from lectures. It is the result of an experience gradually gained in the school of the world. But humanistic studies do tend, in some slight measure at least, to create the spirit of human understanding and of human sympathy, and that advantage (and I believe it is a real advantage), may be gained from them, and should not be

withheld from the prospective engineer. To learn something of the great masters of the world in philosophy, in art, in literature and in the guiding of national destinies, gives him not only a realizing sense of the secret of human power and attainment but suggests to him also the secret of how to make actual the potential energy that is always to be found in groups of men with whom he will have to deal, whether they be laborers, soldiers, or the directors and stockholders and colleagues in some great engineering enterprise.

The engineer who compels the forces of nature and the powers of man to conspire to do his bidding, who brings to his task, whether great or small, a creative spirit, who regards obstacles as a challenge gladly welcomed, and who has the courage to attempt that which to men of restricted vision seems impossible, such is the one who not only attains success as an engineer but is capable of contributing richly to the advancement of knowledge.

Autogenous Welding and the Unfired Pressure Vessel Code

The scope of the proposed code for the safe construction of unfired pressure vessels is far greater than was at first anticipated by the Boiler Code Committee of the A.S.M.E. which is now formulating this code to supplement its rules for the construction of steam boilers.

The demands from the state and municipal authorities for a code covering unfired pressure vessels have been insistent and the Boiler Code Committee has, as a result, been at work for over two years on this supplementary code. In this endeavor, however, it has been a difficult matter to adequately provide for all types and classes of pressure vessel construction and the fact that autogenous welding has been widely introduced for the construction of the joints of such pressure vessels has materially complicated the situation.

As the most recent development in this work, the Boiler Code Committee held a hearing on Monday, December 5, during the A.S.M.E. Annual Meeting, for those who were interested in the manufacture or use of unfired pressure vessels, to consider and discuss the proposed code for unfired pressure vessels, of which a preliminary draft was issued previous to the meeting. This pamphlet was the result of over two years of investigation and conference with allied organizations, and in it there was presented a constructive suggestion for this long-desired code.

The results of the investigations of the Sub-Committee on Welding were shown in the form of proposed specifications for autogenous welding, forge welding and brazing. While there was an attempt to render the code comprehensive, still every detail of either the construction requirements or the various specifications on which there had been lack of agreement were omitted and fourteen questions were listed for discussion at the end of the report.

This preliminary report had been distributed to nearly 500 individuals and concerns known to be interested in the manufacture or use of unfired pressure vessels considerably in advance of the meeting. The result was a large attendance at the hearing during both forenoon and afternoon sessions.

The preliminary draft of the proposed code was read paragraph by paragraph and discussion invited on each. The responses to the fourteen questions at the end of the report furnished the committee with much constructive data for use in shaping the proposed code into final form.

The committee finds that one of the major problems involved is the question of the use of autogenous welding and every endeavor will now be made to bring out the greatest possible amount of information concerning this form of welding in its relation to pressure vessel construction. To this end the A.S.M.E. Meetings Committee, the American Welding Society and the Boiler Code Committee are planning a special welding session at the coming Spring meeting of the Society to be held in Atlanta, Ga., May 8–11. It is expected that a number of welding experts who have carried on extensive research in this field will report there.

Charles Russ Richards Elected President of Lehigh University

Charles Russ Richards, at present Dean of the College of Engineering of the University of Illinois and Director of the Engineering Experiment Station, was elected President of Lehigh University at a meeting of the Trustees held February 7

Dean Richards was born at Clarks Hill, Ind., on March 23, 1871. He was graduated from Purdue University with the degree of Bachelor of Mechanical Engineering in 1890 and a year later received the degree of Mechanical Engineer at the same Institution. In 1895 he obtained his Master's degree in mechanical engineering from Cornell University and in 1920 the University of Nebraska conferred on him the degree of Doctor of Science.

He was instructor in mechanical engineering at the Colorado Agricultural College during the year 1891–92. From 1892 to 1911 he taught at the University of Nebraska holding successively the positions of Adjunct Professor of Manual Training, Professor of Practical Mechanics, Professor of Mechanical Engineering, Associate Dean of the Industrial College, and Dean of the College of Engineering.

CHARLES RUSS RICHARDS

In 1911 he went to the University of Illinois where he has held in succession the positions of Professor of Mechanical Engineering, Acting Dean of the College of Engineering and Director of the Engineering Experiment Station. In March, 1917, he was appointed to succeed Dean W. F. M. Goss.

At the University of Illinois, under the general direction of Dean Richards, the work in the college shops has been completely reorganized so that they have been converted into laboratories to provide instruction in the principles of industrial management in the art of manufacturing to illustrate the effect of the shop processes on the materials of instruction, and to do experimental and research work in connection with the cutting of metals and in the general field of engineering production. It is felt that the method employed in these laboratories constitute a distinct contribution to the field of engineering education.

Dean Richards has served as consulting engineer in connection with the power-plant and water-works problems and the appraisal of public utilities. He has been interested in engineering research relating to fuels, steam, air, and gas-power engineering.

He was elected to membership in the Society in 1892 and served as manager from 1918 to 1921. He is Chairman of the Power Test Codes Sub-Committee on Fuels. He also belongs to the Western Society of Engineers, Society for the Promotion of Engineering Education, Sigma Xi, Tau Beta Pi, Sigma Chi and Sigma Tau.

Herbert Hoover Emphasizes Duty of Engineers in Reestablishing Economic Balance

In Address at Annual Meeting of the American Engineering Council, Secretary of Commerce Indicates the Responsibilities of the Profession and Suggests Steps Toward Fulfillment

THE first Annual Meeting of the American Engineering Council was held in Washington, D. C., on January 5 and 6. An account of the proceedings of this meeting was included in the January 7 issue of *A.S.M.E. News*. The delegates to the Council gathered with the engineers of Washington at dinner on Thursday evening, January 5 and were addressed by Herbert Hoover, past-president American Engineering Council, Dr. Bedrich Stepanek, Minister from the Czecho-Slovakian Republic and John Temple Graves, journalist. Mr. Hoover's address inspired the subsequent deliberations of the Council by his call to the engineering profession for greater service. We are giving his remarks in full.

Fellow engineers: I did not come prepared with any large and efficient words of wisdom and have been rather fearful that I did not sit down in council with your directors and develop someting.

I am interested in this association not only because I participated—I do not put it higher—in the organization of the Council, but because this body has entered upon a path of public service that is unique in the whole United States. I have perhaps said before in urging some of our brother societies to join with the Council, that the engineer has developed himself all these years to the upbuilding of the material values of the United States He has done that effectively—more effectively than has been accomplished in any other of the great countries of the world. The birth of this society marks the evolution of the engineer into an interest in public affairs. With his intelligence, his experience and training and the unique knowledge that he possesses not only of the material but the intangible values amongst our people, he is now organized so that his united voice may become heard outside of his profession. We have probably 175,000 engineers in our country, representing an intellectual possibility for service possessed by no other group. It is therefore an augury of real social development when the engineers of the United States join together for purposes of public service.

This association has the unique value among the associations that it cannot have any material interest for its purpose. No engineer can receive any material benefit from it. It can advance no economic interest. It cannot therefore be charged with any ulterior motive. It is accepted by the whole American people who have become acquainted with its objectives as being clearly single-minded.

During the last year we considered a number of the problems that confront the American people in the light of what services the engineers could perform in their solution. We resolved early in the progress of the Council to undertake an investigation into the elimination of waste—a problem with which the engineer alone was fitted to deal, a problem that had not come in for solution outside of engineering circles. As a result of the investigation carried on during the past year and of the report made, there has been an enormous expansion of the consideration of these fundamental questions—questions that enter into the whole problem of the standard of living of our people. At the time we undertook that investigation we were still at the height of a boom. The country was going on recklessly spending, with extravagance and over-expansion. Almost every engineer, in consideration of the economic situation of the time and the early meetings of the Council, wondered when it would all come to an end and appreciated the waste that came from the operation of the business cycle, which reaches its peak in booms like that then affecting the country. That investigation resulted in a final report in the midst of the depression that was inevitable. It came just at a time when the country was receptive for ideas that in the long run must mean the correction of these tremendous losses from over-expansion and from depression.

On taking this position that I now hold I had felt that it was the duty of the Government, if it was possible, to carry into effect some of the purposes outlined by the Council. We have in the Department of Commerce, accordingly, established a number of agencies intended to effect the results outlined as possible. And in getting further knowledge and experience with this problem I am indeed impressed with the fact that it is the most fundamental of all of the economic problems with which the American people must deal. It becomes doubly important now because we are faced with certain primary conditions that cannot, in my view, receive any solution except along the lines laid down in that report on the elimination of waste.

If we take the year 1913 as a base year for economic calculation and assume that the price of goods to the producer was 100 and likewise the cost to the consumer was 100, and if we then examine the situation today we will find that in many, in fact the majority of cases, the value of commodities is not far from 100 in their return to the producer and, more particularly, we will find the agricultural products often far below that level. But, on the other hand, to the consumer, the price level is, in the majority of cases, from 150 to 170. We have, therefore, a tremendous distortion. That distortion bears heavily on the producer and the consumer. One or the other of the two must carry the brunt of that load. And if we are to decrease that margin, it can only be through the elimination of waste.

We have to bear in mind that during these last seven years we have probably added eight billions per annum to national, state, and municipal taxation. If, on the basis of the present value of the dollar, we estimate that the national productivity of the country is somewhere near fifty billions, it is possible to calculate at once that taxation alone accounts for at least twenty units out of the sixty or seventy with which we have to deal.

There are other elements that have entered into the problem—increased cost of transportation and a thousand direct or indirect increases in the cost of manufacture or distribution.

And, clearly, unless we can bring the cost of commodities to the consumer more nearly into line with the return to the producer, we shall indeed, to go no further, reduce our agricultural population to the status of the European peasant.

That is a problem of manufacture, transportation, and distribution. The distortion is not due to undue profits at the present time. It is distortion that can be corrected only through the elimination of wastes in our processes of distribution and other phases—transportation, business methods manufacture, and so on. Indeed the question of the elimination of waste entered into two years ago because of those glaring, outstanding instances that challenged every engineer now looms in the mind of every economist as the real hope of reestablishing economic balance in the United States.

We have enlarged our vision as to what constitutes waste. We are suffering today from one of the most fearful wastes that can come to us in that we have from two to three millions of idle men. Lost labor once over the dam is lost for all time. Any inquiry into the causes of our vast unemployment brings us at once to consideration not alone of the world as a whole and of our own economic cycle in relation to it but also to the problem of how to avoid such periods of waste.

Now, the engineers have rightly pointed out that there are times when we make large increases both in the direction of plant and equipment and production of consumable commodities; that if we are to correct and alleviate the intensity of our business cycles, we must find some method by which we can expand our plants and equipment at periods when the demand for consumable goods has relaxed. Nor is that a misconception. For if we were to hold over a part of our seasonal operations on great public utilities and public works through periods of from seven to ten years, a reserve of probably no more than ten per cent stored up for periods of depression in the production of consumable goods would enable us to maintain an even tenor and to secure even production of all commodities. There lies one of the greatest wastes and it is in the anticipation of that waste that lies one of the great economic problems of the country.

There are many ramifications of the waste problem with which you are familiar—many, more familiar than I am. But there is one factor in the saving of waste that I believe the engineers might give further consideration to and perhaps more investigation. And that is the problem of a larger view in electrification.

We are all aware of the results obtained in the investigation of the superpower development of the Atlantic seaboard. Superpower is not impossible in many other sections of the country. We are indeed on the threshold of enlarging the distances of transmission. We have the possibility of reducing waste through a large phase of electrical development made during the past thirty years. The American people have no appreciation of the possible results and the added efficiency, productivity, safety and advance that could be obtained in the enlargement of our entire electrical equipment. And there is nobody that could give this problem such consideration and so illuminate it in the national sense as this Council could do. It indeed requires the services of every branch of engineers that compose the Council. With the possibility ahead of us of the development of some twelve to fifteen millions of horsepower, the consolidation of hundreds, even thousands of minor plants, the enormous savings to be made through the substitution of electrical power for steam—in that there is a probability of the greatest material saving of waste possible in any country in front of the American people.

Now, it is one thing to suggest a problem and another thing to suggest its solution. It is a far more difficult thing to state a problem in a fashion that people will understand and state its solution in a fashion that will carry conviction. But an association of this kind, ramifying as it does into the best intelligence of every single community of the United States, has the opportunity to develop popular conception of its ideas more effectively than any other group in the country.

Still, I am not attempting to outline to you the services that you can undertake, for you have on your docket a long list of matters which must be given study and advancement. Thus I understand that you have had before you some question in the matter of a publication. That subject was up when I participated in your deliberations. We recognize the necessity of cohesion among the engineers. The objectives of the Council can be phrased in the common language of the great visions of engineers in the direction of the services they can perform for their communities. And in the contact of engineers with the public life of the Nation there is no possibility of overlapping in the technical services of our member societies.

I realize that the financing of such a publication as some of our members contemplate is of extreme difficulty. Yet, when we entered upon the publication of the Report on Elimination of Waste, we faced an expenditure of

some forty or fifty thousand dollars, and found that there were enough men ready to aid in carrying the investigation through. I do not therefore assume that the necessary expenditure in this case is insuperable but I do believe that one of the strongest measures that can be taken by the Council in promoting the unity of its own membership and the cohesion that it will create is some form of a service journal. And it is not alone a problem for your directors that the engineers should be reported in the public councils of the Nation but it is a problem of inspiring the same attitude of mind amongst the engineers in every city, town, and village in the United States. There is no State or city or municipal government that does not need the advice of the Engineering Council. There is no problem either in Federal or State or municipal legislation that does not at some point touch upon material construction and therefore come within the purview of the engineer. So that while the Council here in Washington and in those centers where the directors can keep in contact with needs and the problems in hand do a great service, the same opportunity and the same need exist throughout the country. I know of no way of inspiring service except by contact. That service the country needs.

It needs the plans and the intelligence of its engineers—the men who have in the very nature of their work the inspiration and enthusiasm and yet are the greatest realists in the world—and they are the men who should be heard from.

For the services you have done during the past year is small measure of what can and will be accomplished by you, through the Council.

Following Mr. Hoover's remarks, Mr. Calvert Towsley, vice-president of the American Engineering Council, presented him with the following resolutions:

Whereas, our first President, Herbert Hoover, has been appointed Secretary of Commerce in the Cabinet of the President of the United States and

Whereas, in consequence of his acceptance of this high public office, he deemed it necessary to tender his resignation as President of The Federated American Engineering Societies,

Be it therefore resolved by American Engineering Council, that we hereby record our appreciation of the rare judgment and vision with which Mr. Hoover has directed the initial policies of The Federated American Engineering Societies, and the ability and uniform courtesy with which he has presided over the deliberation of the Council and the Executive Board.

Be it further resolved that American Engineering Council acting through its Executive Board express to him the sincere regret with which his resignation has been accepted and its sincere good wishes for a continuation of that distinguished success which has followed him in his past services to this profession, his country and mankind.

In acknowledging the presentation, Mr. Hoover said:

Gentlemen, I very much appreciate this expression but I do feel that because I did not give the services to the American Engineering Council while I was its president that I should have given, the Council was the product of your four vice-presidents.

Any man likes to have such things, to treasure in his household, for they bring back recollections of the sweetest things in life.

And I accept them too, in view of the day when I shall have to return to the profession to earn my daily bread, when I shall need such a certificate of character.

So I shall have them framed, and have them ready for the engineer's office that stares me in the face. Nor would I be sorry to re-enter a profession whose sole passion is to build and to construct, for those indeed are the greatest privileges given to man.

I thank you.

American Welding Society Issues First Number of Proceedings

The first number of the Proceedings of the American Welding Society has just reached us. This publication will deal with the activities of the American Welding Society and its Research Department, which is organized as the American Bureau of Welding. Technical papers, research items and other notes of interest to those engaged in the art of welding will appear as well as news of the American Welding Society and its sections.

The American Welding Society is to be congratulated upon its enterprise in developing this medium of communication with its membership. Its form is readable, attractive and dignified.

Announcement of the DeLameter-Ericsson Tablet Committee

At the Commemoration meeting, December 3, 1919, fourteen organizations participated. Afterward it was decided to turn the money that was left over into a fund which would be increased sufficiently to erect bronze tablets on the sites of four buildings with which the lives and work of the two men who were being memorialized were identified. Seven more organizations then joined the movement and it was decided to assess each the sum of $250 and thus raise a fund of $5000 which amount was deemed necessary for the plan proposed. Some of these organizations have over-subscribed their quota, others have not met theirs There is about $1000 still to be raised.

The following members of the A.S.M.E. subscribed the amounts specified:

H. R. Towne	$50.00
H. F. J. Porter	11.00
J. W. Lieb	10.00
G. M. Newcomer	10.00
S. Bevin	5.00
V. D. Bevin	5.00
A. Falkenau	5.00
D. S. Jacobus	5.00
D. J. Lewis, Jr	5.00
Alex Schein	3.00
A. Hollender	1.00

The Committee would welcome further subscriptions. Checks should be drawn to the DeLamater-Ericsson Tablet Committee and forwarded to the headquarters, 29 West 39th Street, New York, N. Y.

Any money remaining after the unveiling exercises on March 9 will be devoted to securing a permanent repository for Capt. Ericsson's models, medals and other memorabilia which are now widely scattered.

Engineering Study of the Pittsburgh District

The Carnegie Institute of Technology has undertaken an investigation of the Pittsburgh district to be carried out on an unusually broad and comprehensive scale. An area covered by a circle of 30 miles radius with the City of Pittsburgh as a center, is to be considered, and the investigation is to embrace power generation, finances, natural resources, transportation facilities, land and labor markets—all from an economic rather than a sociological point of view. It will differ in this way from the majority of previous similar investigations.

Since the fields covered are so diverse that no one individual could undertake such a study, the Carnegie Institute of Technology has alloted the power problem to its engineering departments, its economic department is working on the finances, the geological department on natural resources, etc., while the whole is under the general supervision of the commercial-engineering department.

The real value of such a study comes not so much from the individual reports, as from comparisons that it is possible to draw and the weighing of one report in terms of the others. For example: at the present time there are no means of telling whether the power, finances and transportation facilities in this district are properly balanced. The report as a whole will disclose such conditions, where they would not have been evident from the individual studies. It should also bring to light certain things regarding labor in its relation to investment and industry.

The Pittsburgh district particularly lends itself to such a survey, both because the industrial density is greater than in any district of equal area in the United States, and especially, for general power study, because certain large divisions of power having complete available records, can be separated with considerable accuracy.

In this connection it is surprising what interest has been manifested in this report. The two large electric power companies have worked together to get the data desired, and the steel and other manufacturers are giving figures that would otherwise be almost impossible to obtain. Data is being collected, not only for the present time, but extending back for a considerable period of years, so that the general industrial trend and growth and the effect of the war can be seen.

Some of the individual reports have progressed more than others, and may be published singly from time to time. One or two are nearing completion, but it will be some time before the complete report can be finished.

The Carnegie Institute of Technology states that they will welcome assistance and information that might help towards a more perfect execution of their important task.

The purpose of the investigation is heartily endorsed by Secretary of Commerce Hoover.

Engineering and Industrial Standardization

New Standardization Projects under the A.E.S.C.

Bolt, Nut and Rivet Proportions. During the past fifteen years or so a considerable number of standards for the external dimensions of bolts, nuts and rivets have been formulated by the societies and associations whose members are vitally interested. These standards are now to be reviewed by a Sectional Committee organized under the Rules of the A.E.S.C.

This Sectional Committee is being sponsored by the Society of Automotive Engineers and The American Society of Mechanical Engineers and the individuals and firms most directly connected with the activities of the former Nut, Bolt and Rivet Institute are lending every possible aid in the organization of the Committee. It is the desire of the Sponsors that every organization, which is in any way interested in this project, be represented on the Sectional Committee.

The board representation which this Committee will have, therefore, will insure the general acceptance of the standards which it will propose to the A.E.S.C. as American Standards. The results of its work, however, will have an international as well as a national significance, for the Swiss through their Commission de Normalisation du VSM of Switzerland have already inquired concerning the American Standard external dimensions of nuts and bolt heads of various kinds.

Safety Code for Compressed Air Machinery. The American Society of Safety Engineers and The American Society of Mechanical Engineers have been designated as sponsors for a Safety Code for Compressed Air Machinery by the American Engineering Standards Committee. The code will include rules for the construction and use of compressors, tanks, pipe lines, and the utilization apparatus where compressed air is the active agent. In accordance with the usual procedure, the code will be formulated by a Sectional Committee composed of representatives designated by the various bodies interested. This Sectional Committee is now being organized by the Sponsors who cordially invite suggestions for the personnel.

Census of Engineers and Others Engaged in Promoting Industrial Safety. All branches of the engineering profession will watch with close interest the results of the safety census now being taken by the National Safety Council. Many engineers are devoting their efforts entirely to safety engineering and practically all engineers have more or less to do with safety principles in their work and are interested in the subject. This census is intended to include, however, all persons engaged in safety and industrial health, and it is believed that this is the first time that any attempt has been made to list all the persons engaged in these activities professionally.

The information which the Council seeks includes (*a*) name and full address of the worker, (*b*) company or organization for which engaged, (*c*) nature of the company's business, (*d*) nature and extent of the present safety activity and (*e*) previous experience. By sending these data promptly to the National Safety Council, 168 N. Michigan Avenue, Chicago, those engaged in this line of work will help to make this census taking a success which will thereby assist the whole safety movement.

Standard Methods for Wood Testing. The American Society for Testing Materials and the United States Forest Service have been designated by the American Engineering Standards Committee as joint sponsors for the development of uniform standard methods of testing wood. This action was taken as the result of a canvass made of the principal national bodies concerned with the proposed project, from which it was apparent that there is a real demand for the work, and that the joint sponsorship here indicated would be acceptable to the industry.

Standardization of Railroad Ties. The American Railway Engineering Association and the U. S. Forest Service have been designated by the A.E.S.C. as joint sponsors for the unification of specifications for wood cross-ties and switch ties for all classes of use including mining ties. The work is to include the grouping of ties with regard to preservative treatment, but not methods of treatment; and inspection rules. This action is in accordance with the recommendations of a conference on railroad ties, to which the following organizations had designated representatives:

American Electric Railway Association
American Railway Engineering Association
American Society of Civil Engineers
American Society for Testing Materials
National Association of Railroad Tie Producers
National Hardwood Lumber Association
National Lumber Manufacturers Association
U. S. Department of Commerce
U. S. Forest Service.

For carrying out the work there will be organized by the sponsors a sectional committee having accredited representatives of the above organizations and of the American Mining Congress, and the American Wood Preservers Association.

A.E.S.C. Calls Conference on Overhead Wire Crossing Specifications

At the request of the American Electric Railway Association, a conference is being called by the American Engineering Standards Committee to decide whether there shall be uniform specifications for the crossing of overhead wires, and to dispose, if possible, of certain differences of opinion in regard to those parts of the National Electrical Safety Code which deal with overhead lines. It will be remembered that the Code has been submitted to the American Engineering Standards Committee for approval. Invitations have been issued to all interested bodies to attend the conference, which will be held March 2 in New York.

The following has been planned for the agenda of the conference:

1 Shall there be a set of national specifications for crossings between overhead electric wire lines and railways, and between different wire lines?
2 If so, what should be its relation on Part 2 of the National Electrical Safety Code, "Rules for the installation and maintenance of overhead and underground electrical supply and signal lines."
3 Can disposition be made of the differences of opinion on Part 2 of the National Electrical Safety Code by
    a Approving the present edition,
    b revising the present edition through a sectional committee of the American Engineering Standards Committee?
4 What procedure shall be recommended for carrying out the conclusions reached by the conference?

The American Electric Railway Association has summarized its reason for calling the conference as follows:

> For many years various associations and interests, either individually or jointly, have developed and in many instances adopted, specifications intended to govern the construction of electric light, power, trolley, signal and communication lines across steam and electric railways.
>
> Recently the National Bureau of Standards has promulgated the National Electrical Safety Code, Part 2 of which applies to the general construction of overhead lines, including requirements at railroad crossings. The differences between the several specifications and codes has led to confusion.
>
> Realizing the desirability of having a standard that would be generally acceptable, the American Electric Railway Association has requested the American Engineering Standards Committee, by conference of the bodies interested, to determine the desirability of developing an American Standard Specification which will include the requirements at railroad crossings.

Insulated Wire and Cable

In the past many engineering societies and commercial organizations have issued standard specifications for insulated wires and cables which have come into very general use. Indeed, at the present time there are something like fifteen such specifications in wide use in the United States.

All these specifications, however, are made to apply to specific industrial uses and little has been done to coördinate them. It has therefore become a matter of concern to both manufacturers

and users of wire to bring about some coördination, with the idea of establishing a definite set of American Standards.

The first step toward this was taken last winter when the following ten engineering societies and other public organizations agreed to act as Sponsors, under the auspices of the American Engineering Standards Committee, for a comprehensive standardization of electric wires and cables for other than telephone and telegraph use:

American Electric Railway Association
American Institute of Electrical Engineers
American Railway Engineering Association
American Society for Testing Materials
Associated Manufacturers of Electrical Supplies
Association of Edison Illuminating Companies
Association of Railway Electrical Engineers
National Board of Fire Underwriters
National Electric Light Association
National Fire Protection Association.

These organizations enlisted the coöperation of several others, and created a comprehensive group of committees to handle the work. The other coöperating organizations are:

Associate Bell Telephone Companies
Electric Power Club
Society of Automotive Engineers
U. S. Department of Commerce
U. S. Department of Navy
U. S. Department of War.

The first meeting of the Sectional Committee was held at the headquarters of The American Society of Mechanical Engineers on Friday, December 6, 1921. At this meeting, a formal plan of organization, and procedure was adopted, officers elected, and the work definitely launched.

There are twelve technical committees to which specific phases of the work have been assigned. Like the Sectional Committee itself, they are organized under the representational plan; that is, they are made up of representatives designated by the various organizations concerned in the particular subject with which each committee deals. These committees with their chairmen are as follows:

Definitions	W. A. Del Mar
Copper Conductors	J. A. Capp
Stranding	H. A. Morss
Rubber Insulation	F. M. Farmer
Impregnated Paper Insulation	D. W. Roper
Varnished Cloth Insulation	L. L. Elden
Magnet Wire	R. W. Longley
Fibrous Coverings	C. B. Martin
Metallic Coverings	W. I. Middleton
Standard Make-Ups	C. A. Greenidge
Export	W. S. Clark
Weatherproof, Heat-Resisting and Similar Materials.	(to be appointed later)

The officers of the Sectional Committee and other members of the Executive Committee are:

Chairman, W. A. Del Mar, Chief Engineer, Habirshaw Electric Cable Co.
Vice-Chairman, E. B. Meyer, Asst. Chief Engineer, Public Service Electric Co., of New Jersey
Secretary, F. J. White, Electrical Engineer, Okonite Company, 501 Fifth Avenue, New York
F. M. Farmer, Chief Engineer, Electrical Testing Laboratories
Dean Harvey, Engineer in Charge of Material Section, Westinghouse Elec. & Mfg. Co.
E. B. Katte, Chief Engineer, Electric Traction, New York Central Railroad Co.
Dana Pierce, National Board of Fire Underwriters.

The task before this Sectional Committee is one of the largest yet undertaken under the auspices of the American Engineering Standards Committee. The total number of engineers participating in the work is over one hundred and thirty, and the list includes most of the men who have achieved distinction in the field of wire and cable engineering.

Five Standards Approved as American Standards

A.S.T.M. Specifications. The American Engineering Standards Committee has approved as Tentative American Standard the specifications of the American Society for Testing Materials for—

Cold-Drawn Bessemer Steel Automatic Screw Stock (A32-14)
Cold-Drawn Open-Hearth Steel Automatic Screw Stock (A54-15)
Methods of Chemical Analysis of Manganese Bronze (B27-19)
Methods of Chemical Analysis of Gun Metal (B28-19)

These specifications may be found in the 1921 volume of A.S.T.M. Standards. Copies may also be obtained from the American Engineering Standards Committee, 29 West 39th St., New York City. Price 25 cents each.

Factory Lighting Code. The Code of Lighting for factory mills and other work places, based upon earlier codes issued by the Illuminating Engineering Society and recently revised by a sectional committee under the sponsorship of this society, has been officially approved as American Standard by the American Engineering Standards Committee.

The code is very brief, consisting of a few rules covering the minimum requirements, from the point of view of safety, for the illumination of traverse spaces during the time of use, methods for the avoidance of glare, and for exit and emergency lighting. Supplementary to the code are numerous suggestions relative to illumination values considered desirable for different classes of work and an outline of the advantages of good lighting.

State lighting laws based upon the I.E.S. code have already been put into effect in Pennsylvania, New Jersey, New York, Wisconsin, Oregon, California and Ohio. The adoption of the code is now under consideration in several other states. Copies of this code may be secured from the American Engineering Standards Committee, 29 West 39th Street, New York City. Price 25 cents each.

All the standards which have so far been approved by the A.E.S.C. are now available bound in a loose-leaf expanding binder appropriately stamped. We are told that recently the Chief of Ordnance of the War Department ordered four of these complete sets for the convenient use of his Department.

American Railway Association and Steel Manufacturers Join the A.E.S.C.

Beginning with 1922, the American Railway Association (Engineering Division) and the Association of American Steel Manufactures became member bodies of the American Engineering Standards Committee.

The Association of American Steel Manufacturers is an organization of forty iron and steel manufacturing companies. Its activities are limited to the standardization of rolling-mill practices, and to the standardization and inspection of iron and steel products. The association was organized in 1895. Its official representative on the American Engineering Standards Committee has not yet been designated.

The American Railway Association, which speaks for practically all the steam railways of the country, has four great technical branches, each having its own secretary, the Engineering and the Mechanical Divisions, and the Signal and the Telephone and Telegraph Sections. The Engineering Division, which is intimately connected with the American Railway Engineering Association, the two organizations having the same officers, covers broadly the civil-engineering activities of the railways. The standardization work in which the two associations are engaged, and which they have accomplished, is very extensive, both in scope and in amount. Mr. E. A. Frink, of the Seaboard Air Line Railway, who is chairman of the standardization committees of the two associations, is the representative of the American Railway Association (Engineering Division) upon the American Engineering Standards Committee.

These two new member bodies bring the total number of national organization represented upon the American Engineering Standards Committee up to twenty-eight, and of representatives to fifty-two.

NEWS OF OTHER SOCIETIES

American Society of Heating and Ventilating Engineers

Many important scientific as well as practical contributions to our knowledge of heating and ventilation were presented at the Twenty-eighth Annual Meeting of the American Society of Heating and Ventilating Engineers held at the Pennsylvania Hotel, New York, January 24 to 26, 1922. The attendance at this meeting was over four hundred. There were five professional sessions, the usual business meeting and a conference of chapter representatives with the National Committee on Chapters. Important committees reporting were those on Code of Ethics, on Legislation and on Revision of the Constitution.

The technical papers were published in the January issue of the Journal of the Heating and Ventilating Society. They included: Improvements in the Process for Cleaning and Drying Air Mechanically by William J. Baldwin; Standardized Method of Measuring Fan Delivery by E. N. Fales; Current Research in Heating and Ventilating by F. Paul Anderson; A Study in Heat Transmission with Special Reference to Building Materials by F. C. Houghton; Temperature, Humidity and Air Motion Effects in Ventilation, by O. W. Armspach and Margaret Ingels; The Control of Blower Motors by Henry G. Issertell; The Under-Feed Stoker by Frank A. DeBoos; and Heat Transfer for Conduction and Convection by W. K. Lewis, W. H. McAdams and T. F. Frost.

The officers elected for the new year were J. R. McCool, President, H. P. Gant, First Vice-President, Samuel E. Dibble, Second Vice-President, Homer Addams, Treasurer, and C. W. Obert, Secretary.

The usual entertainment features included the annual dinner-dance at the Hotel Pennsylvania, a reception-dance and functions for the ladies.

American Society of Civil Engineers

The sixty-ninth annual meeting of the American Society of Civil Engineers, held in the Engineering Societies Building, New York, January 18–20, 1922, was devoted to the subject of Transportation, one technical session being on Water Transportation, one on Railroad Transportation, and three on Highway Transportation. A large proportion of the speakers, many of whom were experts in financial and economic subjects, dealt with the economic side. At the evening session of January 19, Mr. Frank A. Vanderlip, former President of the National City Bank, delivered an address on World Activities and their Effect upon the Engineer. These features emphasized the financial aspect of the meeting, which is quite important at this time to civil engineers, since millions of dollars of contracts for civil-engineering work are being held in abeyance pending the world-wide adjustment of the financial situation.

A feature of interest at the meeting was the conferring of Honorary Memberships on five distinguished engineers, M. Charles Prosper Eugene Schneider, of Paris; Dr. Luigi Luiggi, of Rome; and Messrs. Samuel Rea, Ambrose Swasey and Howard A. Carson. M. Schneider was the recipient of the John Fritz Medal presented to him in Paris last year by the Delegation of American Engineers to Europe, and both he and Mr. Swasey are Honorary Members of The American Society of Mechanical Engineers.

Mr. John R. Freeman, Past President, Am.Soc.M.E., was elected President of the Society for the coming year.

Excursions of the meeting included visits to the Stock Exchange, the foundations of the new Federal Reserve Building, the Plant of the McGraw-Hill Publishing Company, and the Hell Gate Power Station of the United Electric Light & Power Co.

Among the speakers at the technical sessions were: Dr. Emory R. Johnson, Dean, Wharton School of Finance and Economy, University of Pennsylvania; R. H M. Robinson, President, United American Lines; Winthrop L. Marvin, Vice-President and General Manager, American Steamship Owners' Association; Samuel O. Dunn, Editor, *Railway Age;* Howard Elliott, Chairman, Northern Pacific Railway Company; William N. Doak, Vice-President, Brotherhood of Railroad Trainmen; Col. F. A. Molitor, Chairman, Board of Economics and Engineering, National Association of Owners of Railroad Securities, together with a number of Commissioners of State Highway Departments of the Eastern States and officials of various financial institutions, as well as several representatives of motor vehicle associations.

Society of Automotive Engineers

The nineteenth annual meeting of the Society of Automotive Engineers was held in New York City, January 10-13, during Automobile Show week. The outstanding feature was emphasis on research in current engineering and this was evident not only in the session devoted to that field, but in the discussions on many of the other subjects.

At the meeting of the Committee on Standards which was the first event following registration, there was a tendency toward revising old standards rather than adopting new ones. An evening session on airplane engines was devoted to the consideration of a paper on Air-Cooled Engines by Charles L. Lawrence, in which he laid particular stress on the relation of cylinder construction to satisfactory cooling.

The Annual Business Meeting on Wednesday morning opened by President David Beecroft with an account of the accomplishments of the Society during this period of Service. The balance of the session was devoted to a review of the general activities of the Society.

Among other items of interest, vice-president H. M. Crane read a report in which he pointed out the commercial achievements in aviation during 1921 and regretted the general handicap of inadequate terminal facilities which must be removed before commercial aviation can be a reality on a large scale. Vice-President Harry L. Horning gave a paper on the desirability of international affiliation of engineers in view of the general economic problems which the world is facing.

The retiring President, in his valedictory, emphasized the opportunities and responsibilities of the engineering profession in the present day. He stressed the need for professional solidarity in meeting the technical phases of the economic problems of reconstruction. The meeting was adjourned after a few remarks by the incoming President, B. B. Bachman of Philadelphia.

In the afternoon three simultaneous sessions were held, covering Body Engineering, Motor Truck Transportation and Lubrication. In the latter Winslow H. Herschel, Associate Physicist of the Bureau of Standards, presented a paper on Viscosity and Friction, one on Fluid Friction and Transmission Efficiency was read by Neal MacCord, and Robert Wilson and W. P. Barnard, 4th, gave The Mechanism of Lubrication.

Technically, at least, the high point of the meeting was reached on Thursday when at a research session the whole morning was given up to Harry Ricardo, the distinguished British engineer whose research work on the factors affecting combustion has attracted so much attention. His paper dealt with the effect of latent heat of vaporization, mean volatility, temperature, pressure, dilution, mixture strength, stratification and other factors upon combustion, and especially the detonation of various fuels for gas engines.

Simultaneous sessions were again held in the afternoon. At one on Fuel and Engines, O. C. Berry and C. S. Kegerreis presented Manifold Vaporization and Exhaust Gas Temperatures; Methods of Measuring Detonations in Engines by Thomas Midgley, Jr., and T. A. Boyd was read; and a paper on Spectroscopic Investigation of Internal Combustion by Thomas Midgley, Jr., and W. K. Gilkey. The other sessions covered Materials and included a paper by C. N. Dawe, on Chrome-Molybdenum-Steel Applications from the Consumer's Viewpoint. G. R. Norton presented Continuous Die Rolling; J. H. Nelson read his paper on Drop-Forging Practice and Enrique Touceda gave Pertinent Facts Concerning Malleable-Iron Castings.

At a Passenger Car Session Friday morning papers by J. Edward Shipper on Passenger Car Brakes; S. von Ammon on Developing a Method for Testing Brake-Lining; and Augustus Trowbridge on Photographic Recording of Engine Data were read.

The meeting was considered the most successful of its kind ever held by the Society and more than seven hundred were in attendance at the technical sessions. The social events included a dinder and carnival at the Hotel Astor.

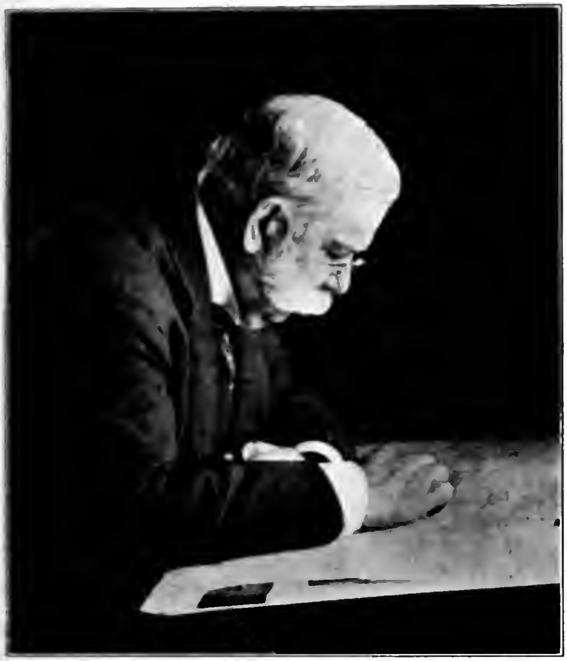
The Life of Westinghouse

By Henry G. Prout, C.E., A.M., LL.D.

A Review by Harrison W. Craver, Director Engineering Societies' Library

SOME years ago the American Society of Mechanical Engineers published the autobiography of John Fritz. It is now responsible for recording in permanent fashion the record of another great engineer, by the publication of this handsome volume.

George Westinghouse was a man of great endowments. Strong of body, distinguished in appearance, he possessed mental powers far superior to those of most men. Formal education he never had: before he was seventeen he enlisted during the Civil War and after being mustered out, two years later, he preferred work in his father's machine shop to a college course. From the close of his military career in 1865, until his death in 1914, he was never idle, but was absorbed in a life of inventing and manufacturing.



A Familiar Picture of George Westinghouse at Work

Such a busy life it was. Merely as an inventor, his record of a patentable invention every six weeks for forty-eight years is one that few inventors have equaled. But invention was for Westinghouse only a preliminary to manufacturing. His patents were for things to be made in his shops or used in his industries, and upon them he based a series of companies. His biographer lists 103 which he organized or assisted during their formative years. They covered America and Europe, and most of them, in one form or another still exist.

The two great achievements by Westinghouse were his solution of the problem of power braking, and his early grasp of the advantages of the alternating current for power distribution. The story of the air brake, from its inception to the perfected mechanism, is well and graphically recounted in this book. It was the first activity that brought Westinghouse into prominence and gave him fame, its supremacy has never been seriously challenged and it remains a monument to its inventor which seems to possess every quality of permanence.

No less interesting is the account of the founding, and development of Westinghouse's electrical interests. The possibilities of the alternating current were seen at an early date, and Westinghouse spent money freely and boldly to uphold his opinion. The story occupies a large portion of the book, and shows how Westinghouse, early interested in electric lighting, turned his attention from direct to alternating current machinery and proceeded confidently and doggedly to prove that his judgment was sound. Step by step the motor, the rotary converter and the distributing system were brought to commercial success, and applied to power production and railroads.

These two main lines of activity by no means exhaust the record. Westinghouse was a pioneer in the development of railway signaling and interlocking, in the natural gas industry and in perfecting the steam turbine. Many minor industries grew up under his care. Wherever he went, he observed, thought and contributed.

Colonel Prout has done a difficult piece of work with great skill. Westinghouse wrote no letters, kept no notebooks and seldom delivered addresses. He left no records to assist his biographer, who has been forced to rely upon the material obtainable from his associates and his personal acquaintance. In spite of the handicap, the record is full and coherent; the man lives, and his achievements are shown in their proper proportions. The picture given places Westinghouse in his proper place in his generation, giving the book value, not only as a biography, but as a contribution to that history of American engineering which is so greatly needed.

The reader will derive additional pleasure from the style in which the book is written. Every line shows the author's intimate acquaintance with the matters of which he speaks, and his ability to express himself appropriately. Any one interested in the lives of our engineers and the history of technical progress in our country, will lay down this book with the hope that its author and the Society will undertake further work of this kind without delay.

[The Life of George Westinghouse was first published in a subscription edition offered to the membership of the American Society of Civil Engineers, the American Institute of Mining and Metallurgical Engineers, The American Society of Mechanical Engineers and the American Institute of Electrical Engineers. A popular edition has been published by Charles Scribner's Sons and may be procured through your book seller.—Editor]

Book Notes

Airplane Engine. By Lionel S. Marks. First edition, McGraw-Hill Book Co., Inc., New York, 1922. Cloth, 6×9 in., 454 pp., diagrams., tables, $6.

This volume attempts to formulate existing knowledge of the functioning of the airplane engine and its auxiliaries, and to present and discuss the essential constructive details of those engines whose excellence has resulted in their survival. Most of the material is new, being based on the researches and developments that originated during the war. Professor Marks has summarized and arranged the detailed data on the engine designs used in various countries, so that it is in convenient form for the designer.

Atomic Theories. By F. H. Loring. E. P. Dutton and Co., New York, 1921. Cloth, 6×9 in., 218 pp., illus., $5.

The leading facts and theories relating to the atom, particularly those which, owing to their newness, have not yet been treated at any length in textbooks, are brought together in one volume for the convenience of students and investigators. The book covers a wide range of subjects. These include the quantum theory, Sir. J. J. Thomson's recent views of mass, matter and radiation, the Bohr theory, the octet theory, isotopes, the Brownian movement, ionization, potentials, solar phenomena and other subjects. References are given throughout, which enable the reader to follow any subject of special interest.

Construction, Cost Keeping and Management. By Halbert Powers Gillette and Richard T. Dana. First edition. McGraw-Hill Book Co., Inc., New York, 1922. Cloth, 5×8 in., 572 pp., forms, $5.

This book has been prepared in response to requests for a second edition of Cost Keeping and Management Engineering. It contains nearly all the original material, supplemented by that developed in the last twelve years. It is intended to assist in reducing construction costs to the minimum, by explaining the rules of management and setting forth suitable methods of cost keeping, adapted to engineering construction.

THE ENGINEERING INDEX

(Registered United States, Great Britain and Canada.)

THE ENGINEERING INDEX presents each month, in conveniently classified form, items descriptive of the articles appearing in the current issues of the world's engineering and scientific press of particular interest to mechanical engineers. At the end of the year the monthly installments are combined along with items dealing with civil, electrical, mining and other branches of engineering, and published in book form, this annual volume having regularly appeared since 1906. In the preparation of the Index by the engineering staff of The American Society of Mechanical Engineers some 1200 technical publications received by the Engineering Societies Library (New York) are regularly reviewed, thus bringing the great resources of that library to the entire engineering profession.

Photostatic copies (white printing on a black background) of any of the articles listed in the Index may be obtained at a price of 25 cents per page, plus postage. A separate print is required for each page of the larger periodicals, but wherever possible two small or medium-sized pages will be photographed together on the same print. When ordering photostats identify the article by quoting from the Index item: (1) Title of article; (2) Name of periodical in which it appeared; (3) Volume, number, and date of publication of periodical; (4) Page numbers. Orders should be sent to the Engineering Societies Library, 29 West 39th Street, New York.

ACCIDENTS

Industrial. The Prodigious Cost of Industrial Accidents, Sanford DeHart. Am. Mach., vol. 56, no. 1, Jan. 5, 1922, pp. 11–13, 3 figs. Statistics on cost of accidents. Instances of reductions in absenteeism and monetary losses. Examples of simple but efficacious safety methods and appliances.

ACCOUNTING

Municipal Utilities. Standard Accounting for Municipally Owned Public Utilities. Jl. Electricity & Western Industry, vol. 48, no. 1, Jan. 1, 1921, pp. 15–16. States that merits or demerits of municipal ownership cannot be determined until there is an adequate basis of comparison of cost of operation. No such basis exists today. Discusses possibility of concealment, challenging of statements, etc.

Power Plants. Power-Plant Accounts—XVI, Wilfred A. Miller. Power, vol. 54, no. 26, Dec. 27, 1921, pp. 1013–1015, 2 figs. General scheme of accounts. (Concluded.)

AIR

Liquefaction. Recent Developments in Low-Temperature Technique (Neuere Entwicklung der Tieftemperaturtechnik), F. Pollitzer. Zeit. für die gesamte Kälte-Industrie, vol. 28, no. 9, Sept. 1921, pp. 125–133, 12 figs. Deals with development of air liquefaction and its applications. Discusses the Linde process for production of very low temperatures, and gives examples of hydrogen-recovery and oxygen plants by the Linde Ice Machine Co., Höllriegelskreuth, Germany.

AIR COMPRESSORS

Displacement, Code for. Code for Displacement Compressors and Blowers. Mech. Eng., vol. 44, no. 1, Jan. 1922, pp. 45–48 and 70. Preliminary draft of fifth in series of 19 codes in course of preparation by A.S.M.E. Committee on power tests codes.

Electrically Driven. Modern Aspects in the Construction of Compressed-Air Power-Transmission Plants (Neuere Gesichtspunkte in der Ausführung von Pressluft-Kraftubertragungen). Elektrotechnische Rundschau, vol. 38, no. 11, June 7, 1921, pp. 63–65, 3 figs. Describes electric compressor constructed by German Gen. Elec. Co. (AEG) for 6000 cu.m. output per hr and 7 atmos. excess pressure, with driving motor of 1485 r.p.m. and 1000 hp.

Machining Components. Machining Air Compressor Components. Machinery (Lond.), vol. 19, no. 480, Dec. 8, 1921, pp. 277 284, 17 figs. Review of methods employed by Reavell & Co., Ltd., Ranelagh Works, Ipswich

Marine Diesel Engines. Design of Air Compressors for Marine Engines, David Bruce. Motorship, vol. 7, no 1, Jan. 1922, pp. 22 24, 11 figs. Discusses compressing and cooling, single-stage and multiple-stage, compressor capacity, spring loads on compressor valves, etc.

AIRCRAFT

British. Modern British Aircraft. Flight, vol 13, no. 45, Nov. 10, 1921, pp. 726 740, 36 figs. Deals with all the British firms at present engaged in airplane and seaplane construction.

AIRCRAFT CONSTRUCTION MATERIALS

Fabric Coverings. The Aging of Aircraft Fabric Coverings (Das Altern des Flugzeugbespannungsstoffes), Fr. Wendt. Zeit. für Flugtechnik u. Motorluftschiffahrt, vol. 12, no. 22, Nov. 30, 1921, p. 325. Based on results of tensile tests with old cellonized covering fabric from upper and lower part of aerofoil and body of an airplane, the loss of strength due to meteorological influences are critically discussed.

AIRPLANE ENGINES

American Pursuit. Development of an American Pursuit Engine. Aviation, vol. 11, no. 26, Dec. 26, 1921, pp. 735–738, 2 figs. Describes developments from the Hispano to the Wright super-fighter developing 400 hp. at 2000 r.p.m. and weighing 610 lb.

British. Modern British Engines. Flight, vol. 13, no. 46, Nov. 17, 1921, pp. 750–757, 21 figs. Describes all the British aero engines being manufactured at present.

Curtiss. The Curtiss Model CD-12 400 hp. Aeronautical Engine. Aerial Age Weekly, vol. 14, no. 12, Nov. 28, 1921, pp. 273–276, 4 figs. Designed primarily for a pursuit engine to give super-performance in high-speed airplanes and now considered past the experimental stage. Detailed description and specifications.

Requirements. The Aeroplane Engine, P. E. Biggar. Eng. Inst. Can. Jl., vol. 5, no. 1, Jan. 1922, pp. 15–21, 8 figs. Requirements of aircraft propulsion and their effect on engine design.

AIRPLANES

Aerofoils. Aerodynamic Characteristics of Aerofoils—II. Nat. Advisory Committee for Aeronautics, report no. 124, 1921, pp. 89–140, 165 figs. Collection of data on aerofoils made from reports of number of leading aerodynamic laboratories of United States and Europe, and presented in a uniform series of charts and tables suitable for use of designing engineers and purpose of general reference. Continuation of Report no. 93.

Developments in Aircraft Design by the Use of Slotted Wings, F. Handley Page. Flight, vol. 13, nos. 51 and 52, Dec. 22 and 29, 1921, pp. 844–846 and 860–861, 17 figs. Deals with applications of slotted aerofoils. Results of tests.

Caproni Triplane. The 2000-Hp. Caproni Triplane (Funfmotoren-2000-PS-Caproni-Dreidecker), E. Meyer. Zeit. für Flugtechnik u. Motorluft-schiffahrt, vol. 12, no. 22, Nov. 30, 1921, pp. 331–332, 4 figs. Machine, which is development of Caproni 3-engine commercial airplane, has five Isotta-Fraschini 400-hp. engines, speed of 140 to 150 km. per hr., and fuel consumption of 200 kg. per hr.; carrying capacity, 30 passengers and 2 pilots. Comparison with German airplanes with 4, 5 and 6 engines.

Commercial Operation. Commercial Operation of Airplanes, L. B. Lent. Mech. Eng., vol. 44, no. 1, Jan. 1922, pp. 33–37. Analysis of record of Air Mail Service of U. S. Post Office Dept. for year ending Sept. 30, 1921. Author points out possible improvements, most important being use of efficient commercial planes equipped with thoroughly reliable power plant. Total operating cost, it is claimed, should not exceed 70 cents per plane-mile for single-engine planes of not over 400 hp.

Landing. The Maneuvers of Getting Off and Landing, R. M. Hill. Aerial Age Weekly, vol 14, nos. 10, 12, 13 and 15, Nov. 14, 28, Dec. 5 and 19, 1921, pp 228 230, 277–278, 300–302 and 348–350. Discusses in detail factors which influence getting off and landing. Lecture delivered before British Aeronautical Soc. See also discussion of above paper in Aeronautical Jl., vol. 25, no. 132, Dec. 1921, pp. 665–671.

Langley. The Langley Machine and the Hammondsport Trials. Aeronautical Jl., vol. 25, no. 132, Dec. 1921, pp. 620–647 (includes discussion), 20 figs. Discusses original Langley flying machine of 1903, and shows that the wings collapsed through faults in design and not from any failure in launching mechanism.

Mars I. Mars I's Wonderful Performance at Martlesham—212 M.P.H. Flight, vol. 13, no. 51, Dec. 22, 1921, p. 838, 1 fig. Built by Gloucestershire Aircraft Co. Results of tests.

Netherlands. New Dutch Airplanes (Neue holländische Flugzeuge), Werner v. Langsdorff. Motorwagen, vol. 24, no. 31, Nov. 10, 1921, pp. 688–692, 4 figs. Details of various models with special reference to the Fokker F III model brought out in 1921, with following specificatious: Span, 16 m.; length, 10.3 m.; height, 3.2 m.; supporting surface, 42 sq. m.; engine, 185-hp. B.M.W. or 230-hp. Siddeley Puma; weight empty, 1200 kg.; loaded, 1900 kg.; carrying capacity, 5 passengers.

New Types. Work of McCook Field in 1921, T. H. Bane. Aviation, vol. 12, no. 2, Jan. 9, 1922, pp. 41–42. Describes new types of airplanes, engines and equipment developed and tested.

Pressure Distribution over Tail Surfaces. The Pressure Distribution over the Horizontal Tail Surfaces of an Airplane—I. Nat. Advisory Committee for Aeronautics, report no. 118, 1921, 86 pp., 264 figs. Account of investigation to determine pressure distribution over two horizontal tail surfaces in uniform free flight.

The Pressure Distribution over the Horizontal Tail Surfaces of an Airplane—II. Nat. Advisory Committee for Aeronautics, report no. 119, 1921, 40 pp., 85 figs. Shows that results obtained upon model tail surfaces can be used to accurately predict loads upon full-sized tail and also to find distribution of load when large elevator angles are used.

Tropical Countries. Aeroplanes in Tropical Countries, Brooke-Popham. Aeronautical Jl., vol. 25, no. 131, Nov. 1921, pp. 563–577 and (discussion) 577–580, 1 fig. Discusses particular troubles that are experienced with airplanes and engines in tropical climates, especially in Egypt and Mesopotamia, viz. timber shrinkage, propellers, tires, shock absorber petrol supply, and hangars.

Wind-Tunnel Tests. Using Results of Tests in the Wind Tunnel for Calculating Full-Size Airplanes (Utilisation des résultats des essais faits sur petits modèles au tunnel aérodynamique pour le calcul des avions en vraie grandeur), E. Dorand. L'Aerophile, vol. 29, no. 19 20, Oct. 1 15, 1921, pp. 290–292. States that the laws of similitude do not apply exactly as between small and large models and proposes corrections necessary.

Zeppelins. Giant Airplanes of the Staaken Zeppelin Works (Grossflugzeuge der Zeppelinwerke Staaken), E. Meyer. Schweizerische Bauzeitung, vol. 78, nos. 24 and 26, Dec. 10 and 24, 1921, pp. 283–286, and 307 309, 13 figs. Dec. 10: Characteristics of Staaken R VI: Span, 42.2 m.; length, 22.2 m.; height, 6.5 m.; engines, four 260-hp. Mercedes, and one 12-hp. Mercedes for drive of a compressor installation; weight empty, 9000 kg.; total weight, 11,600 kg.; max. speed, 160 km. per hr.; climb to 3000 m., 66 min. Dec. 24: The 1000-hp. all-metal com-

mercial monoplane, type 1920, with 31 m span and 3500-kg carrying capacity, weight empty, 5000 kg; speed, 211 km. per hr., cabin capacity, 12 passengers.

AIRSHIPS

Colonial Service. Organisation of a Colonial Airship Service, V. C. Richmond. Aeronautical Jl., vol 25, no. 131, Nov 1921, pp. 588-615, 3 figs. Reviews activities in America, France and Germany; comparative value of airships and airplanes for an imperial air service, discusses general, technical, flying, and financial organisation, etc.

Mooring Masts. A Portable Airship Mooring Mast. Aviation, vol. 11, no. 26, Dec. 26, 1921, p. 732, 1 fig. Describes U. S. Army Air Service mast consisting of four sections of 18 ft. each, capable of mooring ships up to 1,200,000 cu. ft. capacity.

Vacuum as Lifting Power. The Variable Vacuum Dirigible, System Vaugean-Gargiulo (Projet de dirigeable, système Vaugean-Gargiulo, à raréfaction variable), E. Garuffa. Le Génie Civil, vol. 79, no. 25, Dec. 17, 1921, pp. 536-541, 13 figs. Describes model exhibited at International Exposition and discusses principle of application of partial vacuum as an ascensive force. A crude-oil two-stroke engine used for driving.

Vacuum Dirigibles (I dirigibili a rarefazione—Il sistema Vaugean a rarefazione variabile), E. Garuffa. L'Industria, vol. 35, no. 19, Oct. 15, 1921, pp. 421-425, 10 figs. Describes the Vaugean system of airships depending on a partial vacuum for lifting power, which is variable and adjustable.

Zeppelin. The Zeppelin Commercial Airship "Nordstern" (Das Verkehrsluftschiff "Nordstern" des Luftschiffbau Zeppelin). Luftfahrt, vol. 25, no. 8, Aug. 1921, pp. 136-139, 6 figs. Specifications of airship built in 1919 and delivered to France in June 1921. Max length, 130.8 m; max. diam. of supporting structure, 18.71 m; max. cross-section, 268.7 sq. m., max height, 21.62 m; gas capacity, 22,550 cu. m., covering is of cotton material entirely cellonised, engine plant includes one 2-engine and two single-engine nacelles, carrying capacity, 30 passengers, crew, 16 to 18.

ALLOYS

Fusible. Fusible Alloys (Les Alliages fusible), Sigma. La Metallurgie, vol. 53, no. 46, Nov. 17, 1921, pp. 2145-2147. Gives list of compositions for anti-friction metals, solders, and other alloys.

[See also ALUMINUM ALLOYS, IRON ALLOYS; LEAD ALLOYS.]

ALUMINUM ALLOYS

Aluminum-Iron, etc. Aluminum Alloys (Note supplémentaire sur les alliages d'aluminium), Léon Guillet. Revue de Metallurgie, vol. 18, no. 10, Oct. 1921, pp. 681-684, 4 figs. Deals with aluminum-iron, aluminium-chromium, aluminium-manganese, and aluminium-cerium.

Aluminum-Zinc. The Thermal Expansion of Aluminum-Zinc Alloys (Ueber die Wärmeausdehnung der Aluminum-Zink-Legierungen), Alfred Schulze. Physikalische Zeit., vol. 22, no. 14, July 15, 1921, pp. 403-406, 1 fig. Results of experimental determinations which were made according to the tube method.

Mechanical Properties. Aluminium and its Alloys—IV, F. A. Livermore. Metal Industry (Lond.), vol. 19, no. 22, Nov. 25, 1921, pp. 420-421 and 422, 1 fig. Alloys of aluminum and copper, and aluminum and zinc, and their mechanical properties and application.

Melting. Aluminium and Its Alloys—V, Frank A. Livermore. Metal Industry (Lond.), vol. 19, no. 25, Dec. 16, 1921, pp. 496-500, 7 figs. Deals with difficulties in melting and discusses the question of pyrometric control.

Ternary Systems. Ternary Aluminum Alloys (Ueber ternäre Aluminiumlegierungen), M. Wachlert. Metall u. Erz, vol. 18, no. 12, June 22, 1921, pp. 298-307, 7 figs. From the ternary systems, copper-zinc-aluminum, copper-tin-aluminum, and iron-zinc-aluminum, alloys with maximum content of 12 per cent of heavy metal in question were produced by means of ingot casting. With their help, structure, specific weight, physical properties and formation of cutting are determined.

AMMONIA

Ammonia-Soda Process. The Heat Balance in the Ammonia-Soda Process (Die Wärmebilanz im Ammoniaksodaprozess), H. Voss. Chemiker-Zeitung, vol. 45, nos. 117 and 120, Sept. 29 and Oct. 6, 1921, pp. 940-942 and 968-970, 1 fig. Notes on chemical part and working order of process, for which attempt is made to formulate a heat balance. Lime-kiln operation, carbonic-acid compressor, ammonia compressor, etc.

Liquid, Specific Volume. Specific Volume of Liquid Ammonia, C. S. Cragoe and D. R. Harper. U. S. Bur. of Standards Sci. Papers, no. 420, Oct. 15, 1921, pp. 287-315, 3 figs. Specific volume—that is, numerical reciprocal of density—of pure liquid ammonia under pressure corresponding to saturation conditions was determined throughout temperature interval −78 to +100 deg. cent., with accuracy of about 1 part in 10,000. Review of previous work is included. Tables of specific volume and density in both metric and English units are appended.

Synthesis. The Claude Synthetic Ammonia Process, Nov. 26, 1921, pp. 665-666 and (discussion) 666-668, J. H. West. Chem. Age (Lond.), vol. 5, no. 128, Discusses catalyst vessels, catalyst material, removal of ammonia from catalyst tubes, cheap hydrogen, and industrial uses of synthetic ammonia.

ANEMOMETERS

Testing. The Testing of Anemometers, James Cooper. Trans. Instn. Min. Engrs., vol. 62, Part I, Nov. 1921, pp. 90-99, 9 figs. Discusses results of tests showing that anemometric measurements are unreliable, especially at the working-faces where exact knowledge is necessary. See also Min. Inst. of Scotland Trans., vol. 42, Part 2, 1921-1922, pp. 44-53, 9 figs.

APPRENTICES, TRAINING OF

Present Scope, U. S. The Training of Workers in manufacture, J. V. L. Morris. Am. Mach., vol. 56, no. 3, Jan. 19, 1922, pp. 85-86. Present scope of apprenticeship in United States. Number of apprentices in various industries. Importance of apprentices in metalworking field.

ASH HANDLING

Power Plants. Ash Handling in Large Generating Stations, L. R. Lee. Power, vol. 55, no. 3, Jan. 17, 1922, pp. 86-90, 6 figs. Deals with handling and disposition of furnace ash, describes several designs of ashpits and points out merits or demerits of each. Describes different methods of ash disposal and provisions that must be made in case there is a failure in operation of ash-disposal system employed.

AUTOGENOUS WELDING

Acetylene Pressure Apparatus. Acetylene Pressure Apparatus in Switzerland (Acetylendruckapparate in der Schweiz). Autogene Metallbearbeitung, vol. 14, no. 21, Nov. 1, 1921, pp. 303-306, 8 figs. Details and operating experiences with high-pressure acetylene plants constructed by Kneubühler & Co., Zürich. Plants installed by Escher-Wyss, Zürich, and other firms have given satisfactory service.

Pipe. Autogenous Pipe Welding, H. B. Iglehart. Welding Engr., vol. 6, no. 11, Nov. 1921, pp. 21-24, 16 figs. Describes tests on welded pipe construction and shows advantages of welded joints.

AUTOMOBILE ENGINES

Chemical Control. A Chemically Controlled Automobile, George Granger Brown. Jl. Indus. & Eng. Chem., vol. 14, no. 1, Jan. 1922, pp. 6-12, 20 figs. Concludes that the combustion or explosion of a gasoline-air mixture is essentially a complex chemical reaction and as such is susceptible to chemical control. The most important consideration is the velocity of reaction, which is determined by concentration, turbulence, and temperature. Paper read before Am. Chem. Soc.

Detonation, Measuring. Methods of Measuring Detonation in Engines, Thomas Midgley, Jr. and T. A. Boyd. Soc. Automotive Engrs. Jl., vol. 10, no. 1, Jan. 1922, pp. 7-11, 4 figs. Discusses various methods employed to measure detonation or fuel knock, such as the listening indicator, temperature and pouncing pin, and describes latter method.

Mitchell. Entirely New Design Embodied in Mitchell Engine. Automotive Industries, vol. 45, no. 24, Dec. 15, 1921, pp. 1158-1160, 6 figs. New features include balanced crankshaft, hot-spot manifold, unusually light cast-iron pistons, pressure-feed lubrication of main bearings, improved combustion-chamber form and thermostatic valve in cooling system.

Poppet-Valve. Italian Manufacturer Reverts to Poppet Valve Engine. Automotive Industries, vol. 45, no. 25, Dec. 22, 1921, pp. 1205-1208, 9 figs. Rotary valve abandoned in new 176-cu. in. four-cylinder engine which is said to develop 43 hp. at 2500 r.p.m. Large jacket space, aluminum pistons, tubular connecting rods, and four-speed gearset. Integral pressed-steel housing used for axle and propeller shaft.

Radiators. Radiator Vent Pipes. Autocar, vol. 47, no. 1365, Dec. 17, 1921, p. 1245, 3 figs. Shows how it is possible to prevent water from escaping out of radiator through vent pipe.

Rickenbacker. Original Engineering Features in New Six-Cylinder Car, J. Edward Schipper. Automotive Industries, vol. 45, no. 26, Dec. 29, 1921, pp. 1258-1261, 7 figs. Describes new Rickenbacker motor made by Rickenbacker Motor Co., Detroit. Extra flywheel at front of engine is said to minimize vibration and permit wide speed range on high gear. Cone clutch running in oil is employed.

AUTOMOBILE FUELS

Calorific Values. Royal Aircraft Establishments Reports, Nos. H. G. 410 and H. 861. Instn. Petroleum Technologists Jl., vol. 7, no. 28, Oct. 1921, pp. 339-351, 5 figs. Methods of determining calorific values of certain unsaturated hydrocarbons; and calorific values of petrols and of petrol fractions.

Sensible Fuels. Total Sensible Heats of Engine Fuels and Their Mixtures with Air, Robert E. Wilson and Daniel P. Barnard. Soc. Automotive Engrs. Jl., vol. 10, no. 1, Jan. 1922, pp. 65-68, 5 figs. Describes methods used by research laboratory of Mass. Inst. of Technology in determining total sensible heat content of Socony gasoline and kerosene and their mixtures with air at temperatures up to 500 deg. cent.

AUTOMOBILES

Front Axles, Machining. Front Axles and Steering Knuckles, Fred H. Colvin. Am. Mach., vol. 55, no. 25, Dec. 22, 1921, pp. 1011-1013, 10 figs. Machining operations of Peerless axle. Spring actuated drilling fixtures which are quickly handled. Holding long work for milling. Automatic lathe work on steering knuckles.

Gear Boxes. Notes on Motor Car Gear-Boxes., H. F. L. Orcutt. Engineering, vol. 112, nos. 2920, 2921 and 2922, Dec. 16, 23 and 30, 1921, pp. 830-831, 870-872 and 897-899, 8 figs. In writer's opinion, based on over 10 years' experiences, gear boxes, generally speaking, are not well designed and are badly made. Discusses defects in design, workmanship and material, and summarizes gear-tooth requirements. Paper read before Instn. Automobile Engrs. (British.)

Halley Chassis. The 35 Hp Halley Chassis. Automobile Engr., vol. 11, no. 156, Nov. 1921, pp. 370-377, 21 figs. Has six-cylinder engine of 1,200 r.p.m. Describes clutch, gearbox, transmission and rear axle, etc.

L. Paulet. The Six Cylinder L. Paulet (La Six Cylindres L. Paulet), H. Petit. La Vie Automobile, vol. 17, no. 743, Dec. 10, 1921, pp. 467-469, 4 figs. Describes engine, speed gear, transmissions, brakes and wheels, etc.

Painting and Varnishing. Manufacture and Application of Automobile Varnishes and Paints, L. Valentine Pulsifer. Soc. Automotive Engrs. Jl., vol. 10, no. 1, Jan. 1922, pp. 12-16. Specifies five basic materials necessary in automobile painting. Engineering systems of application and methods of application, including drying and surfacing. Care of finish.

Rolls-Royce Works. Rolls-Royce Methods. Eng. Production, vol. 3, nos. 63, 64 and 65, Dec. 15, 22 and 29, 1921, pp. 565-569, 589-596 and 613-618, 44 figs. Details of plant and production methods.

Service Methods. Automotive Service Methods and Equipment, Howard Campbell. Am. Mach., vol. 55, no. 26, Dec. 29, 1921, pp. 1026-1028, 10 figs., and vol. 56, no. 2, Jan. 12, 1922, pp. 59-61, 8 figs. Servicing the Rolls-Royce. Describes interesting grinding job. Kelly-Springfield truck service methods and tools. Servicing the Mack truck. Operation in a New York taxicab station.

AVIATION

Commercial. State of Commercial Aviation (Ou en est l'aviation commerciale), Roger Couturier. L'Aérophile, vol. 29, no. 21-22, Nov. 1-15, 1921, pp. 322-332, 7 figs. Discusses landing facilities, air posts, signals, French air regulations and air-lines in operation.

Development. The Trend of Aviation Development, J. G. Vincent. Soc. Automotive Engrs. Jl., vol. 10, no. 1, Jan. 1922, pp. 25-30. Discusses influences that are retarding development of aviation in an effort to point out the limitations that exist as differentiated from misconceived non-existent limitations and to indicate remedial measures to stimulate a vigorous growth of aviation.

B

BARRELS

Steel. The Making of Steel Pitch Barrels. Sheet Metal Worker, vol. 12, no. 25, Jan. 6, 1922, pp. 841-843, 15 figs. Describes equipment and operations for fabricating steel pitch barrels as modern shipping containers.

BEAMS

Broad-Flange. Production of Broad Flange Beams of the Grey Type at the Differdange Works [La fabrication des poutrelles a larges ailes du type Grey, aux Usines de Differdange (Luxembourg)], J. Audigé. Le Génie Civil, vol. 79, no. 21, Nov. 19, 1921, pp. 437-439, 9 figs. Discusses characteristics of Grey profiles; successive passes through different rolls for broad parallel flange beams.

Continuous. Calculation of Continuous Beams (Le calcul des portiques continus), L. Descans. Le Génie Civil, vol. 79, nos. 21 and 22, Nov. 19 and 26, 1921, pp. 439-443, and 461-464, 12 figs. Nov. 19: Discusses characteristics of continuous beams, calculation of loads, etc. Nov. 26: Analytical formulas.

Deflection. Deflections of Beams by the Conjugate-Beam Method, H. M. Westergaard. Jl. Western Soc. of Engrs., vol. 26, no. 11, Nov. 1921, pp. 369-396, 28 figs. Discusses standard methods, statically determinate beams, and statically indeterminate beams.

BEARINGS, ROLLER

Railway Cars. Ball and Roller Bearings for Railway Cars (Kugel- und Rollenlager für Schienenfahrzeuge), H. Behr. Zeit. des Vereines deutscher Ingenieure, vol. 65, no. 49, Dec. 3, 1921, pp. 1260-1264, 20 figs. Explains reasons for introducing roller bearings. Suggestions for selection of suitable bearings. Roller bearings are said to have better load conditions than ball bearings. Describes new German types of bearings and discusses foreign types and their defects.

BELTING

Leather. Problems In Connection with Leather Belting, J. Edgar Rhoads. Can. Machy., vol. 26, no. 25, Dec. 22, 1921, pp. 24-25. Use of roller and ball bearings; common causes of trouble; humidity and its effect.

Reclaimed Leather. Reclaimed Leather Belting. Machy. (N. Y.), vol. 28, no. 5, Jan. 1922, pp. 363-365, 6 figs. Use of salvaged leather belts reinforced with woven cotton fabric. Processes employed by Syracuse Belting Co. in manufacture of reclaimed belting.

BENDING MACHINES

Cup-Leather Sleeve Friction. Friction of Cup-Leather Sleeves, Eugen Irlon. Mech. Eng., vol. 44, no. 1, Jan. 1922, pp. 59-60, 2 figs. Presents data of tests of friction carried out in a 75-ton hydraulic bending machine water-driven by a three-piston electric pump. Translated from Zeit. des Vereines deutscher Ingenieure, vol. 65, no. 39, Sept. 24, 1921, pp. 1016-1017.

BLIND

Employment. Employment of War-Blinded in German Industries, Hubert Hermanns. Am. Mach., vol. 55, no. 26, Dec. 29, 1921, pp. 1023-1025, 6 figs. Methods used to enable blind ex-soldiers to live inde-

pendent of charity. Machine operation in manufacturing plants.

BOILER FEEDWATER

Distilled. Distilled Water for Boiler Feed at River Rouge Plant. Power, vol. 54, no. 26, Dec. 27, 1921, pp. 998–1003, 10 figs. Elaborate two-effect high-heat-level evaporator system furnishes distilled makeup to an amount up to 25 per cent of boiler feed.

Softening. Softening and De-oxygenation of Boiler Feed Water. Chem. Age (Lond.), vol. 5, no. 130, Dec. 10, 1921, pp. 726–728. Discusses comparative merits of water-softening systems, importance of effecting oxygen removal, and chemical and physical methods for performing de-oxygenation.

BOILER OPERATION

Efficient. Better Boiler Room Operation, C. W. De-Forest. Combustion, vol. 5, no. 6, Dec. 1921, pp. 246–248 and 260. Discusses investment cost; cost of fuel; and organization, personnel, supplies and maintenance costs. Paper read before Stoker Manufacturers Assn.

BOILER PLANTS

Battle Creek Sanitarium. New Boiler Plant for Battle Creek Sanitarium. Power, vol 55, no. 2, Jan. 10, 1922, pp. 46–49, 6 figs. Installation of modern boiler house saved 10 tons of coal a day and eliminated services of 9 men from operating force. Includes full complement of instruments giving all essential operating data.

Electricity in. Electricity in Steam-Boiler Plants (Elektrizität in Dampfkesselanlagen), W. Philippi. Siemens-Zeit., vol. 1, nos. 9 and 10, Sept. and Oct. 1921, pp. 312–321 and 373–380, 21 figs. Sept.: Deals with pneumatic ash-removal installations. Oct.: Electrolytic protection of boilers against scale and corrosion. Describes method, success of which is said to have surpassed all expectations. Consists of externally generated direct current, applied through electrodes into boiler.

Management. Boiler House Management, David Brownlie. Proc. South Wales Inst. Engrs., vol. 37, no. 5, Nov. 10, 1921, pp. 405–438. Types of boilers and their relative advantages and disadvantages; mechanical stoking; economizers and feedwater heaters; superheaters; forced and induced draft; auxiliary machinery.

BOILER ROOMS

Air Supply. The Air Supply to Boiler Rooms, Richard W. Allen. Eng. & Indus. Management, (Cassier's Marine No.), Dec. 1921, pp. 35–42, 9 figs. One of most important points is that there should be equal distribution of preheated air to furnaces, so that no currents are set up and each furnace receives equal supply of air. Author deals with this problem. Results of trials taken under same conditions on one class of ship over period of four years show gains effected in each year as experience is accumulated.

BOILERS

Design. Boiler Design and Other Fuel Efficiency Factors, F. G. Lister. Ry. Rev., vol. 70, no. 1, Jan. 7, 1922, pp. 5–8, 4 figs. Discusses fuel efficiency of locomotives by attention to mechanical details. Longer combustion chambers; flexible staybolts; tight front ends; floating bushings; automatic stokers; etc.

BOMBS

Bombing and Bomb Sights. Bombing and Bombing Sights, E. J. Loring. Sci. Am., vol. 126, no. 1, Jan. 1922, pp. 49–51, 6 figs. How aiming from unstable platform of airplane is made possible.

BORING MACHINES

Standardization. Standardization and Assimilation—II, H. Varley. Eng. & Indus. Management, vol. 6, no. 23, Dec. 8, 1921, pp. 650–652, 1 fig. A scheme of standardized boring practice.

BRASS

Corrosion. The Problem of Selective Corrosion and Dezincing of Brass (La problème des corrosions sélectives et de la dézincification des laitons), F de. Wurstemberger. Révue de Metallurgie, vol. 18, no. 11, Nov. 1921, pp. 689–712, 26 figs. Discusses in detail dezincing process and concludes that it consists of two factors, anodic dissolving of the metal and cathodic deposition of copper. Gives results of tests and indicates protective means.

BRONZE CASTINGS

Manganese. Investigation of Methods of Making Manganese Bronze Castings to Meet Air Service Specification No. 11021. Air Service Information Circular, vol. 3, no. 275, Oct. 15, 1921, 28 pp., 9 figs. For purpose of developing satisfactory method for making manganese bronze in small foundry; standardizing method of separately casting test specimens as a check on melts of small castings of this metal; and determining best physical properties obtainable in manganese bronze as determined by this standard test bar, and comparing these with results obtained on test bars cut from actual castings.

BRONZES

Manganese. Manganese Bronze, Frank A. Livermore. Metal Industry (Lond.), vol. 19, no. 23, Dec. 2, 1921, pp. 445–446. Shows that manganese bronze may be manufactured from scrap metal without resorting to use of high grade virgin metal.

C

CAR LIGHTING

Methods. Railway Car Lighting (L'éclairage des voitures de chemins de fer), M. Bougrier. L'Électricien, vol. 52, nos. 1287 and 1288, Nov. 1, and 15, 1921, pp. 481–488 and 505–513, 11 figs. Nov. 1: Describes the various methods in use in different countries, including lighting by candle, oil, gas, acetylene, and electricity, and gives cost data. Nov. 15: Describes the Brown-Boveri individual electric equipment, its operation and upkeep.

CAR WHEELS

Foundry. A Unique Foundry for Production of Car Wheels. Can. Foundryman, vol. 12, no. 11, Nov. 1921, pp. 17–20, 6 figs. Molds are placed on semi-automatic moving platform and taken to place of pouring; shaking out and annealing with very little effort.

Tires, Sorbitic Steel. Sorbitic Steel for Tires. Engineer, vol. 132, no. 3442, Dec. 16, 1921, p. 636, 4 figs. on p. 657. Includes tables showing results of tests made with three railway and three tramway tires, one of each set being treated by the Sandberg Sorbitic steel process. Results show that process is successful in obtaining improved ultimate tensile strength and hardness of tires.

CARS

Connectors. The Development of the Robinson Connector. Ry. Age, vol. 71, no. 26, Dec. 24, 1921, pp. 1259–1263, 9 figs. Detailed description of new design incorporating a number of improvements.

CARS, COAL

Electric Tippers. Electrically Equipped Railway Truck Tippers, E. H. Rousham. Electrician, vol. 87, no. 2276, Dec. 30, 1921, pp. 822–825, 10 figs. Describes the Babcock & Wilcox tipping ram, and the tipper manufactured by Ed. Bennis & Co., Ltd.; also overhead winch type, hydraulic tipping rams, electric rotary tipplers, clamping methods, automatic clamping gear, etc.

CARS, FREIGHT

Wood Construction. The Use of Wood in Freight Car Construction, H. S. Sackett. Ry. Mech. Engr., vol. 96, no. 1, Jan. 1922, pp. 27–32, 6 figs. Advantages of composite design as against all-steel construction; relative advantages of double and single sheathed box car; composite gondola car; refrigerator car.

CARS, PASSENGER

Electric Railway. New Stock For Tynemouth Electrified Branches, North Eastern Railway. Ry. Gaz., vol. 35, no. 24, Dec. 9, 1921, pp. 877–884, 12 figs. Passenger vehicles of improved design built for this important electrified passenger service.

Sleeping. New Sleeping Cars for the Canadian Pacific. Ry. Age, vol. 71, no. 27, Dec. 31, 1921, pp. 1301–1394, 7 figs. Composite cars of 12-section and compartment types have special facilities for comfort of passengers.

CASE-HARDENING

Iron and Steel. Case Carburizing of Iron and Steel (Härtung von Eisen und Stahl), Willy Hacker. Metall-Technik, vol. 47, no. 14, Sept. 15, 1921, pp. 85–87. Review of development and processes during last few years.

CASTING

Metal Molds. Casting in Metal Moulds, S. A. E. Wells. Metal Industry (Lond.), vol. 19, no. 25, Dec. 16, 1921, pp. 501–502. Discusses the three classes, viz., (1) that in which metal flows into mold under force of its own weight, (2) die castings, and (3) part chills in ordinary sand molds. From paper read before joint meeting of Inst. of Metals and Instn. British Foundrymen.

Permanent Molds. Permanent Moulds, Edward D. Gleason. Metal Industry (Lond.), vol. 19, no. 20, Nov. 11, 1921, pp. 377–379. Description of methods of making plaster molds for finished castings to eliminate machining operations.

CELLULOID

Manufacture. Manufacture of Pyroxylin Plastics, J. R. DuPont. Chem. & Met. Eng., vol. 26, no. 2, Jan. 11, 1922, pp. 65–70, 6 figs. Properties of celluloid; methods of mixing cellulose nitrate with camphor and alcohol; stabilizing; filtering; rolling; baking; sheeting; polishing; etc.

CHROME STEEL

Ball-Bearing. The Manufacture of Chromium Ball-Bearing Steel in the Heroult Furnace, F. T. Sisco, Chem. & Met. Eng., vol. 26, no. 2, Jan. 11, pp. 71–76, 2 figs. Description of melting and processing of electric ball-bearing steel, with a view of the most serious defects in this class of material. Recommended pratice for elimination and control of these defects.

Chrome-Molybdenum. Chrome-Molybdenum-Steel Applications from the Consumer's Viewpoint, C. N. Dawe. Soc. Automotive Engrs. Jl., vol. 10, no. 1, Jan. 1922, pp. 47–50 and 62, 2 figs. Gives results of physical tests, comparing medium-carbon, chrome-molybdenum, chrome-vanadium, chrome-nickel and chrome steels. Discusses case-hardening grades of Steel.

COAL HANDLING

Equipment. Springdale Mine Furnishes Fuel to West Penn Power Co. Plant, Cleaning Every Car of Coal Before Weighing, D. J. Baker. Coal Age, vol. 20, no. 25, Dec. 22, 1921, pp. 993–999, 6 figs. Power plant situated next to headframe. For weighing, coal is screened to lump, nut and slack before picking; nut and slack are united and reassembled; lump is then crushed and with nut and slack goes to boilers.

Plants. Up-to-Date Coal and Ash Handling Plant at the Cordite Factory, Poole. Eng. & Indus. Management, vol. 6, no. 24, Dec. 15, 1921, pp. 701–704, 8 figs. Railway sidings on which coal arrives and on which ashes leave, run alooside of and parallel with boiler house; full trucks arrive on inner track and pass an unusually large track hopper into which coal is dumped by truck tippler.

COAL STORAGE

Concrete Bins and Pits. Economy of Concrete Bins and Pits for Coal Storage, A. C. Irwin. Elec. Rev. (Chicago), vol. 79, no. 22, Nov. 26, 1921, pp. 811–816, 16 figs. Storage requirements and methods, including submerged pits; effect of storage on properties of coal; spontaneous combustion.

COMBUSTION

Gas Mixed with Air. Perfect Combustion of Gas by Mixing With Air (Réalisation de la combustion par faite du gaz par son mélange préalable, incomplet avec de l'air), A. Grebel. Chaleur et Industrie, vol. 2, no. 20, Dec. 1921, pp. 794–802, 14 figs. Recent progress in construction and operation of gas apparatus and gas burners, application in welding, annealing, etc.

COMPRESSED AIR

Handling Material by. Handling Material by Compressed Air, F. A. McLean. Can. Machy., vol. 26, no. 25, Dec. 22, 1921, pp. 19–23, 10 figs. Time is saved and economy effected. Notes on single acting air hoists, capacities of straight lift hoists, and operating costs.

Intercooling. Value of Intercooling Compressed Air, C. K. Bennett. Nat. Engr., vol. 25, no. 12, Dec. 1921, pp. 613–616, 6 figs. Advantages of intercooling. How saving in power is effected and safety maintained.

CONVEYORS

Machinery for Elevators and. Conveying and Elevating Machinery, Gardiner Mitchell. Engineering, vol. 112, no. 2921, Dec. 23, 1921, pp. 866–870, 17 figs. Deals with the various types of conveyors and elevators, and includes tables giving standard details and particulars, and standard elevator chains.

Steel-Band. The Use of Steel Bands for Power Transmitting and Conveying Purposes, Bernard Kruger. Jl. Western Soc. of Engrs., vol. 26, no. 12, Dec. 1921, pp. 428–432. Discusses increased use of steel bands, avoiding breaks in band, composition and tensile strength of bands, and compares leather, rope, chain and steel band systems.

COPPER

Working and Annealing. Experiments in the Working and Annealing of Copper, F. Johnson. Engineering, vol. 112, no. 2922, Dec. 30, 1921, pp. 899–901, 7 figs. Results of rolling and hardness tests and specific gravity tests. Notes on annealing of rolled strips, and influence of impurities on effective annealing temperature of cold-drawn copper. (Abstract.) Paper read before Inst. Metals (British).

CORK

Artificial. Artificial Cork, Ismar Ginsberg. Sci. Am., vol. 126, no. 2, Feb. 1922, p. 91, 5 figs. Waste materials used in its manufacture and applications found for it.

CORROSION

Investigations. Corrosion Investigations, D. M. Strickland. Sci. Am., vol. 126, no. 2, Feb. 1922, p. 104, 2 figs. Some of controlling factors, and how account is best taken of them.

COST ACCOUNTING

Idleness Expense Charts. The Cost of Mismanagement, E. A. Lucey. Management Eng., vol. 2, no. 1, Jan. 1922, pp. 25–28, 4 figs. How it can be measured through idleness. Shows examples of Gantt idleness charts.

COSTS

Construction. Calculation of Costs in Engineering Construction (Die Kostenberechnung im Ingenieurbau), Hugo Ritter. Schweizerische Bauzeitung, vol. 78, nos. 10 and 11, Sept. 3 and 10, 1921, pp. 116–119 and 131–133. Suggestions as to how the separate expense items which go to make up total cost of a work can best be determined. Deals with cost of labor and material, mechanical equipment, transportation, general expenses, etc.

Foundry. Foundry Costs and Establishment Charges, Daniel Adamson. Engineering, vol. 112, no. 2922, Dec. 30, 1921, pp. 891–895. Author endeavors to arrive at a reliable method of estimating cost of many varieties of castings in green sand, dry sand or loam, that are produced in foundry attached to a general engineering business. Notes introducing discussion before Manchester Assn. Engrs.

CRANES

Hooks for, Strength of. The Strength of a Hook or "Clivvy," Charles D. Mottram. Quarry & Surveyors' & Contractors' Jl., vol. 26, no. 297, Nov. 1921, pp. 447–449, 4 figs. Discusses safety load and factor of safety; gives curves and formulas.

Overhead Drives. Overhead Crane Drives, A. W. Knight. Machinery (Lond.), vol 19, no. 482, Dec. 22, 1921, pp. 352–354, 4 figs. Describes some typical cranes and works out amount of movement of one side of crane in advance to the other, when the crab and its suspended load is at opposite end to drive on cross shaft.

Shifting Gear on Gantry. Use Shifting Gear on German Cranes. Iron Trade Rev., vol. 70, no. 2, Jan. 12, 1922, pp. 140–142, 5 figs. Describes gantry cranes equipped with swivel trucks and lifting jacks by means of which whole crane may be quickly and readily transferred from one runway to another. Built by Fried. Krupp Corp., Magdeburg-Buckau.

CRANKSHAFTS

Manufacture. The Manufacture of Crankshafts. Engineering, vol 112, nos 2919 and 2920, Dec. 9 and 16, 1921, pp 777-778, 9 figs partly on supp plate, and pp. 811-813, 14 figs Describes works and manufacturing methods of Clarke's Crank & Forge Co., Ltd., Lincoln, England

CUTTING TOOLS

Diamond. Manufacture and Use of Diamond Cutting Tools, Ellsworth Sheldon Am Mach., vol 56, no 2, Jan 12, 1922, pp 53-56, 8 figs Study of structure necessary to secure keen cutting edges Cleaving the diamond.

D

DIE CASTING

Plant Organization. Modern Production of Die-Molded Castings (Neuzeitliche Pressgussherstellung), Harry Bachme Elektrotechnische-Rundschau, vol. 38, no. 18, Sept 21, 1921, pp 105-107, 1 fig Describes organization of modern plant for making die-molded castings and reviews metals now commercially used in die-casting practice.

DIES

Continuous Rolling. Continuous Die Rolling, G. R Norton Soc Automotive Engrs Jl., vol. 10, no. 1, Jan. 1922, pp 43-46, 11 figs Describes process of continuous die rolling, improvements made, physical characteristics of steels, cost of operation, equipment used, etc. See also Iron Age, vol. 109, no 3 Jan 19, 1922, pp 207-209, 11 figs

DIESEL ENGINES

Air Compressors. See AIR COMPRESSORS, Marine Diesel Engines.

Generator Drive. Oil-Engine-Driven Ship Generators in the Germany Navy (Der ölmotorische Antrieb von Borddynamos in der deutschen Kriegsmarine), W. Landah Schiffbau, vol. 22, no 34, May 25, 1921, pp 813-819 and vol 23, no 12, Dec 21, 1921, pp 329-339, 10 figs Notes, including official data, on development of high-speed Diesel engines for dynamo drive May 25 Fundamental principles of construction Dec. 21 Results of tests with different types; engines of 300-kw. output. The opposed-piston-type engines built by Weser Corp., Bremen, for the liner, Markgraf. (To be continued.)

Investigations. Investigations of Diesel Engines (Untersuchungen an der Dieselmaschine), Kurt Neumann Forschungsarbeiten auf dem Gebiete des Ingenieurwesens, no 245, 1921, 42 pp., 18 figs. Based on tests, results of which are presented in tables and diagrams, progress of combustion and interchange of heat between gas and cylinder wall are determined. Progress of combustion is determined by means of indicated diagrams and from composition of gas specimens taken from working cylinder of engine Thermodynamical calculations are based strictly on measurements and are entirely free from arbitrary assumptions. Analysis of injection and combustion process. Calculation of loss of work due to conduction through walls of cylinders.

DRILLING MACHINES

Heavy-Duty. Economy of Heavy-duty Drilling, Fred R. Daniels Machy. (N. Y.), vol. 28, no. 5, Jan. 1922, pp. 349-355, 16 figs. Examples of work for which heavy-duty drilling machine is adapted.

DROP FORGINGS

Heat Treatment. Heat-treatment of Drop-forgings. Machy (N Y), vol 28, no. 5, Jan. 1922, pp 384-388, 6 figs Furnace design and fuels suitable for treating drop forgings.

DUST

Collectors. Mechanical Methods of Allaying Dust, P H Warren Australasian Inst. Min & Metallurgy Proc., no 42, June 30, 1921, pp. 31-47 and (discussion) 47-100, 10 figs. Describes tests carried out at Broken Hill South mine with the Clifton dust, collector

E

EDUCATION, ENGINEERING

Industrial Needs. Engineering Education. Mech. Eng., vol 44, no 1, Jan 1922, pp 1-7 and 42. Group of papers in which are presented particular needs of industries and problems that confront engineering faculties Professional Engineering Education for the Industries, Francis C. Pratt. A National Policy on Engineering Education, A. G. Christie Engineering Education as Viewed by the Industrialist, J E Otterson.

EDUCATION, INDUSTRIAL

Germany. The Training Schools of the German Mechanical Industry (Die Werkschulen der deutschen mechanischen Industrie). Betrieb, vol. 3, nos. 23, 25 and 26, Aug. 27, Sept. 15 and 25, 1921, pp. 53-56, 57-64 and 65-76, and vol. 4, no. 2, Oct. 22, 1921, pp. 1-9. Notes on training schools of most important German industrial works.

ELECTRIC DRIVE

Sugar Mills. Electric Drive for Sugar Mills, Charles Griffith. Sugar, vol. 24, no 1, Jan. 1922, pp. 33-34. This type of power development has advantage of flexibility and many economies are effected by unit drive.

Wool Cards. Group vs. Individual Drives on Wool Cards, Alonzo B. Reed. Textile World, vol. 61, no. 1, Jan 7, 1922, pp. 63-65 and 81, 2 figs General comparison of first cost, power consumption, maintenance, cleanliness and flexibility of operation with different systems of driving. Tests made under actual mill conditions before and after cards were equipped with individual motors.

ELECTRIC FURNACES

Arc, Operation of. The Operation of Basic Electric Furnaces M W Caruthers. Iron Age, vol 109, no. 1, Jan 5, 1922, pp. 17-19 How to avoid delays in each of the eight major operations of making steel in furnaces having movable electrodes.

Basic. Basic Electric Furnace for Cast Iron Can. Foundryman, vol 12, no 11, Nov. 1921, pp. 32-34. Important characteristics of refining in the basic-hearth electric furnace are: (1) it is strongly reducing, (2) it is degasifying to an appreciable extent, (3) it is cleansing of entrained slags and oxides, and (4) it is intensely desulphurizing.

Electrodes. Electric Furnace Electrode Has Undergone Marked Development, A. T. Hinckley. Elec. World, vol 78, no 26, Dec. 24, 1921, pp. 1263-1265. Reviews uses of carbon electrodes from 1800 to present day applications in electric furnace.

Forging. Builds Electric Forging Furnace, G. M. Little. Iron Trade Rev., vol. 69, no. 26, Dec. 29, 1921, pp. 1689-1692, 3 figs. Discusses difficulties encountered in construction of carbon resister-type furnace for heat treating and forging work Gas or oil used to prevent resister oxidation. Insulation problem solved.

Gray-Iron. Practical Aspects of Electric Gray Iron, C H Vom Baur Iron Age, vol. 109, no. 1, Jan. 5, 1922, pp. 51-52. Advantages over the cupola. Actual results from heats made recently. Effect of nickel and chromium. Comparative costs.

Induction. Melting Steel in an Induction Furnace, H A Winne. Iron Trade Rev., vol. 70, no. 2, Jan. 12, 1922, pp 138-139, 2 figs. Describes induction furnace of 4000-lb. hearth capacity in successful operation at Pittsfield works of Gen. Elec. Co for more than a year. It is a single-phase, single-ring (horizontal) type; lining consists of two essential parts, an outer layer of insulating and refractory brick, and inner rammed lining, or hearth proper.

Railway Shops. The Electric Furnace on Railroad Work, Larry J. Barton. Western Machy. World, vol. 12, no. 11, Nov. 1921, pp. 444-446, 4 figs. Describes installation of Southern Pacific Co. at their Sacramento shops; 6-ton Heroult furnace.

Reactance Requirements. Furnace Reactance Requirements Need Consideration, P. B. Short. Elec. World, vol 79, no. 2, Jan 14, 1922, pp. 81-83, 4 figs. Discusses growing tendency to use higher operating voltages and the importance which public utilities are attaching to power factor.

Steel. Electric Furnace Best for Conditions on the Pacific Coast, L. J. Barton. Jl. Electricity & Western Industry, vol. 47, no. 12, Dec. 15, 1921, pp. 463-464, 1 fig. In iron and steel manufacture efficiency of electric furnace and high quality of product offset absence of coking coal necessary for blast furnace methods.

ELECTRIC LOCOMOTIVES

Paulista Railway D. C. 3000 Volt Direct-Current Locomotives for the Paulista Railways, John A. Clarke, Jr. Elec. Jl., vol. 19, no. 1, Jan. 1922, pp. 17-23, 11 figs. Discusses electrification of Jundiahy-Campinas section of the Sao Paulo state railway, and gives data on passenger and freight locomotives and auxiliaries.

Storage-Battery. Data on Operation of Storage Battery Locomotive, Jerome C. White. Coal Industry, vol. 4, no. 12, Dec. 1921, pp. 581-583, 2 figs. Costs and operating data obtained from a storage-battery locomotive used as a main haulage machine. Paper read before Coal Min. Inst. of Am.

Explosion Proof Electric Mine Locomotives, L. C. Illsley. Coal Industry, vol. 4, no. 12, Dec. 1921, pp. 588-591, 9 figs. Description of work being carried on by Bur. of Mines in connection with investigations of storage-battery locomotives; requirements for approved equipment; rules for inspection.

Haulage Work with Storage-Battery Locomotives Without Driver (Förderbetrieb mit fuhrerlosen Akkumulator-Lokomotiven), H. Trautvetter. Fördertechnik u Frachtverkehr, vol. 14, no 23, Nov. 11, 1921, pp. 287-289, 4 figs. Maximum speed of locomotive is 1 m. per sec.; efficiency, 80 to 100 km. per 8 hr.; under these conditions capacity of batteries is sufficient for 8000 to 10,000 m. Enumerates advantages of driverless locomotives.

ELECTRIC PLANTS

Automatic. Automatic Plant Permits Development of Small Power Site, C. M. Gilt. Elec. World, vol 78, no. 25, Dec. 17, 1921, pp. 1213-1214, 3 figs. Generator started simply by energizing line connecting automatic plant to main station.

Commonwealth Edison Co., Chicago. Calumet Station of the Commonwealth Edison Co., A. D. Bailey. J. Western Soc. of Engrs., vol. 26, no. 12, Dec. 1921, pp. 420-427, 9 figs. Discusses station now under construction, with ultimate capacity of 180,000 kw.; present installation consists of one 30,000-kw. Westinghouse Tandem compound unit and one 30,000-kw. General Electric unit Boiler station to consist of seven 1,500 hp. Babcock & Wilcox boilers fired with forced-draft chain-grate stokers and augmented with superheaters and steel-tube economizers.

Hartford Electric Light Co. Station Electrical Layout for Supplying Local and Regional Service. Elec. World, vol. 78, no. 26, Dec. 24, 1921, pp. 1269-1273, 9 figs. Flexibility and simplicity of design effectively combined in South Meadow station of Hartford Elec Light Co Symmetrical development by sections to meet dual service.

Possible Economies. Possible Economies in Large Electric Generating Stations, Emile Rauber Engineer, vol 132, no 3444, Dec. 30, 1921, pp 669-670. States that considerable progress may still be made in economizing fuel by (1) using higher steam pressures; (2) employing higher degree of superheat; (3) heating feedwater by "bleeding" turbines; and (4) preventing all losses of heat. (Abstract.) Report of Commission appointed by French Minister of Pub. Works, printed in Journal Officiel.

ELECTRIC POWER

Industrial Load, Pennsylvania. The Industrial Load in Pennsylvania. Elec. World, vol. 78, no. 27, Dec. 31, 1921, pp. 1313-1317, 3 figs. Electrical energy consumed by all industrial plants of Pennsylvania during 1920 is estimated at 4,666,928,000 kw-hr., 50.3 per cent of which is purchased from central generating and distributing systems.

ELECTRIC WELDING, ARC

Boiler Repairs. Electric Arc Welding for Boiler Repairs. Ry. Elec. Engr., vol. 12, no. 11, Nov. 1921, pp. 415-420, 19 figs. Special committee of Master Boiler Makers' Assn. reports best methods of reconditioning boilers.

Cyc-Arc Process. The "Cyc-Arc" Process of Automatic Electric Welding, L. J. Steele and H. Martin. Electrician, vol. 87, no. 2273, Dec. 9, 1921, pp. 734-735. Discusses development; and the three essential variables, viz., (a) amount of current through the arc, (b) length of arc upon striking, and (c) length of time it had to be maintained before making the weld. Results of welding experiments and tests with the cyc-arc apparatus.

ELECTRIC WELDING, RESISTANCE

Methods and Apparatus. Electric Resistance Welding (La soudure électrique par résistance), R. Verdier. La Nature, no. 2480, Oct. 15, 1921, pp. 246-251, 7 figs. Describes the three methods and apparatus used.

Railway Shops. Experiences with Machines for Electric Resistance Welding in Railway Shops (Erfahrungen mit Maschinen zum Schweissen durch elektrischen Widerstand in Eisenbahnwerkstätten), W. Bastänier. Organ für die Fortschritte des Eisenbahnwesens, vol 76, no. 17, Sept. 1, 1921, pp. 177-179, 5 figs. Describes machines by Moll Works Corp., Chemnitz, Germany, for butt-welding and spot welding, and experiences therewith in railway shop.

EMPLOYEES' REPRESENTATION

Advantages. Pulling Together Through Representation, John T. Broderick. Management Eng., vol. 1, no. 6, Dec. 1921, pp. 331-334 and vol. 2, no. 1, Jan. 1922, pp. 31-36. Dec. Points out that right understanding comes from joint conference of employer and employee. Jan. Manufacturer explains plan adopted in his plants. Describes how general committee is formed, how wage problem is solved, and production helped, attitude of organized workers, problem of unemployment, welfare work, etc.

EMPLOYMENT MANAGEMENT

Adaptability Tests. How to Develop Psychological Adaptability Tests (Wie entwickelt man phychologische Eignungsprüfungen), Hans Rupp. Betrieb, vol. 4, no. 4, Nov. 26, 1921, pp. 96-105, 15 figs. The most important practical fundamentals for development of reliable adaptability tests are set forth.

Psychotechnical Adaptability Testing of Prospective Female Workers for Mass Production in the Electrical Industry (Psychotechnische Eignungsprüfung von anzulernenden Arbeiterinnen der elektrotechnischen Massenherstellung), M. Waldau. Betrieb, vol. 4, no. 4, Nov. 26, 1921, pp. 110-117, 27 figs. Describes methods and testing apparatus and their evaluation.

ENAMELING

Cast Iron and Steel. Enameling Cast Iron and Steel Materials, F. L. Prentiss. Iron Age, vol. 109, no. 1, Jan. 5, 1922, pp. 13-16, 9 figs. Methods and apparatus used. Care needed in preparing surfaces for treatment. Burning on the enamel.

ENAMELS

White, for Copper. The Production of Some White Enamels For Copper, R. R. Danielson and H. P. Reinecker. Am. Ceramic Soc. Jl., vol. 4, no. 10, Oct. 1921, pp. 827-834. Describes investigations for developing white enamels for copper watch dials, thermometer scale plates, and signs. Preparation of enamels; application and firing of enamels.

ENGINEERING

Western Home for. Proposed Western Home for Engineering and Industry, Robert Sibley. Jl. Electricity & Western Industry, vol. 47, no. 11, Dec. 1, 1921, pp. 426-427, 1 fig. Discusses plans for financing and managing a large building in San Francisco to be used as center for all classes of engineering.

ENGINEERING SOCIETIES

Engineering Association Plans. The Engineering Association and Its Plans, C. S. Kimball. Elec. Ry. Jl., vol. 59, no. 1, Jan. 7, 1922, pp. 18-20, 1 fig. Discusses work of reorganization of Am. Elec. Ry. Assn.; outlines committee problems and activities; participation in national standardization; etc.

ENGINEERS

License Law, N. Y. State. The New York State License Law, S. G. George. Cornell Civil Engr., vol. 30, no. 4, Jan. 1922, pp. 53-54. Professional engineers and land surveyors required to obtain

licenses to practice in New York State from May 5, 1923.

ENGINEHOUSES

Enterior Turntable. Rectangular Enginehouse with Interior Turntable. Eng. News-Rec., vol. 87, no. 26, Dec. 29, 1921, pp. 1064–1066, 4 figs. Two Canadian railways adopt novel plan to reduce winter trouble at terminal by putting turntable under cover

EXHAUST STEAM

Utilization. Utilization of Exhaust Steam in Industries (Abdampfausnutzung in der Industrie), J. Gramberg. Gesundheits-Ingenieur, vol. 44, no. 51, Dec. 17, 1921, pp. 633–638 and (discussion) pp. 638–641, 8 figs. Discusses conditions essential for design and efficient operation of plant for utilizing exhaust steam. Address before Heating & Ventilating Congress at Munich.

F

FACTORIES

Layout. Factory Lay-out as an Aid in Reducing Costs. Machinery (Lond.), vol 19, no. 480, Dec. 8, 1921, pp. 293–296, 8 figs. Describes new plant of Colburn Machine Tool Co., Cleveland, Ohio, which has been laid out with a view to economy in manufacturing.

Laying Out a Factory for Production Work, Frank W. Curtis. Am. Mach., vol. 56, nos. 2 and 3, Jan. 12 and 19, 1922, pp. 56–58 and 97–99, 8 figs. How kind and amount of equipment are estimated. Arranging machines. Uses of operation sheets, equipment records, and conveyors.

Telephone. Methods in a Telephone Factory. Eng. Production, vol. 3, no. 64, Dec. 22, 1921, pp. 583–587, 14 figs Describes works and practice of British L. M. Ericsson Mfg. Co., Ltd., at Beeston, for manufacture of telephones, telephone exchange and private branch switchboards and allied apparatus cabinet work, etc.

FACTORY MANAGEMENT

See INDUSTRIAL MANAGEMENT.

FILING SYSTEMS

Z Charts. Filing the Z Chart, Arthur R. Burnet. Management Eng, vol. 2, no. 1, Jan. 1922, pp. 47–50, 2 figs. Describes system of filing which, it is claimed, follows principles best suited to classification and indexing of accounting records.

FLIGHT

McCook Field Altitude. Functioning of Supercharger in Altitude Flight. Aviation, vol. 12, no. 2, Jan. 9, 1922, p. 51. Excerpt of report of John A. MacReady on his record-breaking altitude flight at McCook Field, dealing with technical aspects of flight and giving summary of data obtained with respect to supercharger, engine and propeller.

Soaring. The Starting of Soaring Airplanes (Start von Segelflugzeugen), E. Offermann. Zeit. für Flugtechnik u. Motorluftschiffahrt, vol 12, no. 22, Nov. 30, 1921, pp. 327–331, 13 figs. Investigation of following problems is said to be necessary in order to diminish danger to life and material: Improvement in airplane construction that will render it possible to start and fly with as low a wind as possible; training of pilot especially for motorless or soaring flight; study of relationships between formation of land and nature of soil and air movements, and their dependence upon one another.

FLOW OF LIQUIDS

Resistance in Glass Tubes. The Resistance of Liquids Flowing in Short Tube Sections (Ueber den Widerstand strömender Flussigkeit in kurzen Rohrstucken), L Schiller and H. Kirsten. Physikalische Zeit., vol. 22, no. 19–20, Oct. 1–15, 1921, pp. 523–528, 7 figs. Discussion of experimental results obtained by W. Sorkau in investigation of friction of liquids in glass tubes.

FLOW OF WATER

Spiral Riveted Pipe. Flow of Water Through Spiral Riveted Steel Pipe, F. W. Crewe and R. R. Martin. Eng & Contracting, vol. 57, no. 2, Jan. 11, 1922, pp. 41–42, 2 figs. Data and results of investigation upon flow of water through 4, 6, 8 and 10-in. galvanized spiral riveted steel pipes, dealing primarily with relation of friction loss to velocity in straight runs, both when flow was directed with and against lap. (Abstract.) Bul. Eng. Experiment Station of Purdue University.

FORGING

Instruction Sheets. Instruction Sheets for Forging (Schmiedeakkorde), F. Lohage. Werkstattstechnik, vol. 15, nos. 10 and 11, May 15 and June 1, 1921, pp. 281–291 and 317–327, 48 figs. Instruction sheets for forging various machine parts, etc., with line allowance for each operation. Illustrations of forging tools and their application.

Mild Steel. Forging Experiments with Mild Steel, Paul J. Junkers. Forging & Heat Treating, vol. 7, nos. 10 and 11, Oct. and Nov. 1921, pp. 518–523 and 553–556, 22 figs. Oct.: Results of experiments to determine resistance of steel to deformations and influence of kneading and forging temperatures upon physical properties of a 0.13 and 0.50 C steel Nov.: Improvement in structure due to forging is greater in 0.50 than in 0.13 carbon steel; finishing temperatures important.

FOUNDRIES

Brass. Casting Small Parts in Production Foundry, Gerard Frazar. Iron Age, vol. 108, no. 26, Dec. 29, 1921, pp. 1653–1656, 7 figs. Describes new foundry of Gilbert & Barker Mfg. Co., Springfield, Mass., equipped for continuous pouring which when run at capacity will give employment to about 300.

Chilled Rolls. New Foundry for Casting Chilled Rolls, George F. Tegan. Iron Age, vol. 109, no. 1, Jan. 5, 1922, pp. 38–42, 7 figs. Raw material charged in air furnaces direct from stock pile at Garrison foundry, Pittsburgh.

Core Mixing. Core and Sand in the Foundry, G. Pouplin. Brass World, vol. 17, no. 12, Dec. 1921, pp. 345–350. The making and mixing of cores as practiced today in the best French foundries. Notes on core drying, glutrin and avebene, and action of tar-oil on sand. (Abstract.) From Fonderie Moderne.

Engineering Costs. Obtaining Engineering Costs in Foundry and Machine Shop, Howell B. May. Iron Trade Rev., vol. 69, nos. 19, 21, 23 and 25, Nov. 10, 24, Dec. 8 and 22, 1921, pp. 1218–1221, 1356–1358, 1456–1458, 1485–1489 and 1619–1622 and 1630, and vol. 70, no. 3, Jan. 19, 1922, pp. 206–210, 30 figs. Survey of needs and advantages of adequate costs with detailed application of cost system to plant having iron and brass foundries, machine shop and sheet-metal department. Nov. 10: General outline of plan. Nov. 24: Cost plan in detail. Dec. 8: Burden and expense account. Dec. 22: Consolidation of cost and general accounting. Jan. 19: Financial statements, graphics and control.

Railway Iron and Steel. Control in a Railway Iron and Steel Foundry, G. N. Shawcross. Engineering, vol. 112, no. 2920, Dec. 16, 1921, pp. 832–836, 6 figs. Outlines examples of control of men, methods and materials in well-known locomotive works of Lancashire & Yorkshire Ry. at Horwich, England, showing what output is produced and by what methods work is turned out. Address delivered before Cambridge University Eng. Soc.

Sand-Dressing Plants. Automatic Sand-Dressing Plant (Selbsttätige Sandaufbereitungsanlagen), H. Kalpers. Zeit. für die gesamte Giessereipraxis, vol. 42, no. 37, Sept. 10, 1921, pp. 481–484, 8 figs. Describes new plant by the Gustav Zimmermann Machine Works, Düsseldorf, which is said to produce a sand of always uniform and excellent quality which contributes greatly to production of good castings.

FRAMES

Rigid, Calculation of. A New Calculating Method for Rigid Frames (Ein neues Berechnungsverfahren für biegungsfeste Rahmen nach H. Bronneck), H. Marx. Dinglers polytechnisches Jl., vol. 336, no. 21, Oct. 22, 1921, pp. 301–302, 2 figs. Describes new method by Hugo Bronneck, with which, it is claimed, calculation of most complicated frame forms (for which few or no formulas exist) can be made without referring to formulas or making new derivations.

FREIGHT HANDLING

Electric Apparatus for. Electrically Operated Apparatus for Handling Railway "General Goods," George Bulkeley. Electrician, vol. 87, no. 2276, Dec. 30, 1921, pp 819–821, 3 figs. Discusses principle of loading general merchandise; limitations of overhead gantry crane; electric platform trucks; etc.

FUELS

America's Resources. America's Fuel Resources, Robert G. Skerrett. Sci. Am., vol. 126, no. 2, Feb. 1922, pp. 86–87, 3 figs. Data on deposits and consumption. Presents charts showing how consumption of petroleum and coal has increased since 1880.

Gaseous Products, Composition of. Formulas for the Control of Gas Composition in Combustion and Gasification Processes and for the Calculation of Air and Exhaust-Gas Volumes (Formeln für die Kontrolle der Gaszusammensetzung bei Verbrennungs- und Vergasungsvorgängen und für die Berechnung der Luft- und Abgasmengen), Gustav Neumann. Stahl u. Eisen, vol. 41, no. 50, Dec. 15, 1921, pp. 1811–1817. Relations between chemical composition of fuels and chemical composition of the gaseous products resulting from their combustion, carbonization or distillation, are numerically determined and expressed in closed formulas.

Ignition Temperatures. The Ignition Points of Fuels According to Recent Tests (Die Zündpunkte von Brennstoffen nach neueren Versuchen), E. Daiber. Zeit. des Vereines deutscher Ingenieure, vol. 65, no. 50, Dec. 10, 1921, pp. 1289–1290, 3 figs. Account of tests on ignition temperatures of liquid and solid fuels. Notes on apparatus used, influence of time on ignition point, values and other results obtained. Comparison of described processes of Moore and Hawkes.

FURNACES

Oxy-Acetylene. An Oxygen-Acetylene High-Temperature Furnace, Hewitt Wilson. Am Ceramic Soc. Jl., vol 4, no. 10, Oct. 1921, pp. 835–841, 2 figs. Detailed description to show use of oxy-acetylene gas in a small furnace for using refractory cones. Advantages of furnace.

FURNACES, BOILER

Solid and Liquid Fuels. The Pace Patent Furnace Door. Iron & Coal Trades Rev., vol. 103, no. 2808, Dec. 23, 1921, p. 917, 1 fig Describes furnace for burning alternatively solid or liquid fuels and gives comparison of cost.

FURNACES, HEATING

Ingot-Reheating. Ingot Reheating Furnace, H. E. Smythe. Iron Age, vol. 109, no. 2, Jan. 12, 1922, pp. 149–150, 1 fig. New design to avoid imperfect and unequal heating by proper control of incoming gases.

FURNACES, INDUSTRIAL

High-Pressure Gas System. High Pressure Gas and Its Application to Industrial Furnaces, F. J. Evans. Am. Soc. for Steel Treating Trans., vol. 2, no. 3, Dec. 1921, pp. 213–222, 7 figs. Discusses low-pressure air and gas system with two-valve control and manual proportioning, and with single-valve control and automatic proportioning, and high-pressure gas system with single-valve control and automatic proportioning.

G

GAS PRODUCERS

Corrosion of Cooling System. Corrosion of a Producer-Gas Cooling System, Lloyd E. Jackson. Chem. & Met. Eng., vol. 26, no. 2, Jan. 11, 1922, pp. 60–64, 5 figs. Cooling water of high acidity and containing much dissolved oxygen and suspended coke dust causes deterioration of cooling system at plant of Providence Gas Co., Providence, R. I. Remedial measures are suggested

Tests with Alberta Coals. Gas Producer Trials with Alberta Coals, John Blizard and E. S. Malloch. Canadian Dept. of Mines, Bul. no. 33, 1921, 40 pp., 23 figs. Tests were carried out in Westinghouse, double-zone, gas producer. Aim of trials was to ascertain suitability of the various fuels for giving a clean combustible gas when burned in the producer. Results show that all fuels except one are suitable but that less than one-half can be recommended for continuous operation in producer.

GAS TURBINES

Efficiency, Determination of The Thermodynamic Principles for Determination of the Expected Efficiency of Gas Turbines (Die thermodynamischen Grundlagen für die Bestimmung des von Gasturbinen zu erwartenden Wirkungsgrades), H. Schmolke. Zeit. für Dampfkessel u. Maschinenbetrieb, vol. 44, no. 44, Nov. 4, 1921, pp. 351–354, 4 figs. Review of works on this subject which have appeared in last ten years. Presents diagrams developed by W. Schüle showing process and efficiency of Holzwarth turbines.

Impulse Type. Prospects of the Gas Turbine in Competition with Other Prime Movers (Die Aussichten der Gasturbine im Wettbewerb mit unseren bisherigen Kraftmaschinen), Hans Kasparek. Oel- u. Gasmaschine, vol. 18, nos. 8, 9, 10 and 11, Aug., Sept., Oct. and Nov. 1921, pp. 121–123, 142–146, 161–164 and 177–179, 5 figs. Notes on impulse gas turbines with turbo-compressors, piston compressors, etc.

GASES

Pump and Mixer. The Roturbo Gas Pump and Mixer. Engineer, vol. 132, no. 3444, Dec. 30, 1921, p. 704, 1 fig. Describes Rees Roturbo gas pump and mixer for creating a very intimate mixture between gases and liquids and so effecting required solution or chemical action in smallest possible time and space. It is designed to draw large volumes of gas from comparatively low vacuum and to mix them with the entraining liquid.

GEAR CUTTING

Broaching Machine. Gear Cutting or Broaching Machine. Eng. Production, vol. 3, no. 65, Dec. 29, 1921, p. 621, 1 fig. Patented method of producing gears, circular cutters, saws, etc., particularly adapted for manufacture on extensive basis, chief feature being cutting of number of teeth simultaneously.

Spur-Gear Machine. Cutting Spur Gears on the Shaper. Eng. Production, vol. 3, no. 64, Dec. 22, 1921, p 587, 1 fig. Describes new gear-cutting attachment, for generation of spur gears having correct tooth form, no matter what the number of teeth.

GEARS

Involute. Design of Bevel, Helical and Worm Involute Gears, A. B. Cox. Am. Mach., vol. 56, no. 3, Jan. 19, 1922, pp. 104–107, 8 figs. Application of data of author's previous articles. Determination of helix and tooth angles. Relation between interference, number of teeth and sliding action.

The Evolution of the Involute Gear Tooth—X, A. Fisher. Machinery (Lond.), vol. 19, no. 483, Dec. 29, 1921, pp. 380–384, 6 figs Discusses relation between tooth depth and thickness; backlash; generating teeth of conjugate thickness.

Tooth Shape. Gear Tooth Shape and Its Relation to Standardization, E. W. Miller. Automotive Industries, vol. 45, no. 24, Dec. 15, 1921, pp. 1167–1173, 26 figs. Discusses properties of involute form of gear tooth. True involute teeth with a certain pressure angle and relation between addendum and diametral pitch will not interfere with pinions down to 12 teeth. Such a system would facilitate universal interchangeability. Condensed from paper read before Am. Gear Manufacturers' Assn.

Worm. Worm Gear Generator. Machy. (Lond.), vol. 19, no. 481, Dec. 15, 1921, pp. 325–327, 9 figs. Describes in detail machine built by Smith & Coventry, Ltd., Manchester.

GIRDERS

Bending Moments. Graphic Determination of Bending Moments in a Girder Supporting Traffic Loads by Means of Cross Bars (Détermination Graphique des moments fléchissants maxima dans une poutre supportant des charges mobiles par l'intermédiaire des traverses), Smoukovitch and Barbillion. Le Génie Civil, vol. 79, no. 25, Dec. 17, 1921, pp. 533–535, 5 figs.

GRAIN ELEVATORS

Explosions. The Northwestern Elevator Explosion, David J. Price. Jl. Western Soc. of Engrs., vol 26, no. 12, Dec 1921, pp. 401–417 and (discussion) 417–419, 7 figs. Discusses in detail damage done to elevator operated by Armour Grain Company, South Chicago, theories advanced as to cause of explosion, lessons to be learned from the explosion, recommendations.

Pneumatic. Pneumatic Grain Elevators, R. E. Knight. Engineering, vol 112, no 2921, Dec 23, 1921, pp. 864–866, 1 fig. Deals with pneumatic discharge of grain from ships, and more particularly with two modern examples of floating and quayside plants in which oil engines or motors, and high-speed rotary exhausters, have replaced vertical or horizontal compound steam engines and reciprocating exhausters, as main power plant of installation. Paper read before Instn. Mech. Engrs. (British). See also Engineer, vol 132 no 3443, Dec 23, 1921, pp. 655–657, 1 fig.

GRINDING

Differential Spider Arms. Grinding Differential Spider Arms, Charles Kotersall. Am. Mach., vol 55, no. 25, Dec 22, 1921, pp. 1009–1010, 3 figs. Method which eliminates use of centers and an inspection gage for insuring accuracy in alignment.

Surface. Why Work Curls Towards the Wheel While Being Surface Ground, E. A. Dixie. Am. Mach., vol 55, no 25, Dec 22, 1921, pp. 1006–1007, 4 figs. Plausible theory deduced from long experience. Work heated beyond critical point in numberless places takes permanent set when quenched by coolant.

GRINDING MACHINES

Railroad Shops. The Grinding Machine in the Railroad Shop, Frank A. Stanley. Am. Mach., vol. 56, no. 2, Jan. 12, 1922, pp. 64–65, 10 figs. Advantages of grinding for finishing parts to size. Grinding operations on locomotive parts. Increasing efficiency of motion mechanism.

H

HANDLING MATERIALS

German Mechanical Devices. Development of Mechanical Handling Devices in Germany during and since the War, George P. Zimmer. Eng. & Indus. Management, vol. 6, nos. 18, 22, 24 and 26, Nov. 3, Dec. 1, 15 and 29, 1921, pp. 514–515, 1 fig.; 645–646, 2 figs.; 706–707, 7 figs. and 760–761, 1 fig. Information resulting from author's visit to German industrial centers. Points out that band conveyor has been superseded by other devices owing to high cost of bands. Nov. 3: Improved automatic colliery tippler. Dec. 1: Mechanical removal of ashes from locomotives. Dec. 15: Latest developments in coal-face conveyors. Dec. 29: Pneumatic handling.

Textile Mills. Material Handling in the Textile Industry, R. M. Gates. Management Eng., vol. 2, no. 1, Jan. 1922, pp. 13–17, 8 figs. Shows types of electric trucks, belt conveyors, gravity conveyors, inclined elevators, etc., employed in textile mills. Points out importance of material handling.

HEAT

Recovery from Earth. Ground Heat as the Most Important Source of Energy (Die Erdwärme als wichtigste Energiequelle). Rauch u. Staub, vol. 12, no. 3, Dec. 1921, pp. 16–18. Review of developments in study of the recovery of heat from earth interior for technical purposes.

HEAT BALANCE

Electric Plants. Heat Balance of the Connors Creek Plant of the Detroit Edison Company, C. Harold Berry and F. E. Moreton. Mech. Eng., vol. 44, no. 1, Jan. 1922, pp. 22–25, 8 figs. Describes briefly apparatus in plant, followed by discussion of ideal operating conditions, and presents actual results. Includes table showing thermal balance sheet for April 1921.

HEAT INTERCHANGERS

Experiments With. Experiments with Heat Interchangers, F. Russell Bichowsky. Jl. Indus. & Eng. Chem., vol. 14, no. 1, Jan. 1922, pp. 62–64, 3 figs. Discusses the Linde, Hampton, and Nelson types of interchangers.

HEAT PUMPS

Evaporators With. Experiences on Evaporators with Heat Pumps, E. Wirth. Mech. Eng., vol. 44, no. 1, Jan. 1922, pp. 49–51, 5 figs. Points out that whereas until now investigations have been made only with regard to liquids with low-boiling point, data are now available on heavier liquids. Account of author's experiences with heat pump operation. Translated from Zeit. des Vereines deutscher Ingenieure, vol. 65, no. 46, Nov. 12, 1921, pp. 1183–1186.

HEAT TRANSMISSION

Problems. Heat Transfer, W. H. McAdams and T. H. Frost. Jl. Indus. & Eng. Chem., vol. 14, no. 1, Jan. 1922, pp. 13–18, 2 figs. Problems arising in the field of heat transfer and rational method for studying them. Results of preliminary experiments to determine numerical value of coefficient of heat transfer between condensing vapors and a pipe.

HEAT TREATING

Plant Operation., The Complete Operation of a Modern Heat Treat Department, Thomas B. Fordham. Factory, vol. 28, no. 1, Jan. 1922, pp. 31–34, 6 figs. Method of control which has been successful in reducing scrap loss and bringing down manufacturing cost.

HEATING, ELECTRIC

Hot-Water. Comparative Investigations of Domestic Heating and Cooking Arrangements (Vergleichende Untersuchungen an häuslichen Heiz- und Kocheinrichtungen), J. Rutishauser and P. Schläpfer. Schweiz. Elektrotechnischer Verein Bul., vol 12, nos 10, and 12, Oct. and Dec. 1921, pp. 259–270 and 376–406, 27 figs. Oct.: Comparative tests on hot-water installations with coke and electric heating. Dec.: Comparative tests on different cooking devices, and comparative cooking tests with a coal oven and electrically heated tipping boilers in the Claradel Sanatorium, Zürich, Switzerland.

HEATING, FACTORY

Bleeder Steam. Using Bleeder Steam in Factory Heating, J. A. McGillivray. Power House, vol. 14, no 22, Nov 21, 1921, pp. 21–27, 11 figs. Bleeder type is especially furnished where low pressure steam is required for heating, in combination with electric motive power. Bleeder types are designed for a variety of conditions of operation, both in condensing and non-condensing units, or any combination of the two.

HEATING, STEAM

Central-Station. Present State of Central Heating Station Practice (La technique actuelle des centrales à vapeur). Le Génie Civil, vol. 79, no 21, Nov. 19, 1921, pp. 433–437. Discusses report of Commission for Utilization of Fuels, types of boilers, economizers, superheating, pre-heating, feedwater, etc. From Journal Officiel.

Equipment. Features of Central Steam Heat Plant Equipment, W. A. Scott. Elec. Rev., (Chicago), vol 79, no 21, Nov. 19, 1921, pp. 759–760, 1 fig. Underfeed stokers provide for boiler operation at 250 per cent of rated capacity; modern coal and ash handling apparatus reduces operating labor; water softener used to treat well water.

Exhaust. House Heating with Exhaust Steam (Raumheizung durch Abdampf), W. Pauer. Archiv für Wärmewirtschaft, vol. 2, no. 10, Oct. 1921, pp. 128–130, 2 figs. Gives fundamental principles for economic arrangement of heating installations, and discusses useful scope of the three types, namely, back-pressure, discharge and condensation.

Heat Utilization. Economic Utilization of Heat in Steam-Heating Plants (Wirtschaftliche Wärmeausnutzung bei Zentralheizungen), H. Pradel. Zeit. für Dampfkessel u. Maschinenbetrieb, vol. 44, nos. 40, 42–43 and 44, Oct. 7, 28 and Nov. 4, 1921, pp. 324–327, 342–344 and 355–357, 24 figs. Review of latest developments in steam-heating plants. Reconstruction of steam heaters in dwelling houses.

HOISTS

Electric. Choice of Anuglar Velocity of a Winding Engine Driven by a Three-Phase Asynchronous Motor (Du choix de la vitesse angulaire d'une machine d'extraction commandée par moteur asynchrone triphasé), Georges Hacault. Révue Générale de l'Électricité, vol. 10, no. 22, Dec. 3, 1921, pp. 813–816, 2 figs. Discusses angular velocity from the point of view of slowing down without loss of energy or mechanical braking.

Mine. Scraping and Loading in Mines With Small Compressed-Air Hoists, Ward Royce. Eng. & Min. Jl., vol. 112, nos. 24, 25 and 26, Dec. 10, 17 and 24, 1921, pp. 925–931, 973–977 and 1014–1019, 50 figs. Use of slushers in underground loading applicable to various mining methods. Types of scrapers in successful use in Joplin, and Lake Superior iron and copper districts, and their application.

HYDRAULIC TURBINES

Bavarian Installations. The Turbines of the Walchensee Plant, Bavaria (Die Turbinen des Walchenseewerks), Georg v. Troeltsch. Elektrotechnische Zeit., vol. 42, no. 47, Nov. 24, 1921, pp. 1351–1354, 5 figs. Preliminary report of hydraulic equipment of unfinished plant in Bavaria. Turbines of total output of 168,000 hp. are being installed, two different types being used in same station, namely, four 24,000-hp. 500-r.p.m. Francis spiral turbines and four 18,000-hp. 250-r.p.m. Pelton wheels, both types operating under head of about 195 m. Comparison of described turbines with others of Francis and Pelton types.

Castings, Making. Making Water Turbine Castings, H. E. Diller. Foundry, vol. 49, nos. 22 and 23, Nov. 15 and Dec. 1, 1921, pp. 873–878 and 920–925, 19 figs. Nov. 15: Describes molding the large scroll-case castings; skeleton patterns keep down expense of equipment. Dec. 1: Method of molding small runners with vanes of curved steel plate and larger sizes with cast-iron vanes.

Efficiency, Determination of. Calorimetric Determination of Efficiency of Hydraulic Turbines (Sur la détermination de rendement des turbines hydrauliques par voie calorimétrique), L. Barbillion and A. Poirson. La Houille Blanche, vol. 20, no. 57–58, Sept.-Oct. 1921, pp. 161–166, 2 figs. Discusses the Rappel method of determining efficiency, based on the transformation into heat of all power losses.

Impulse Type. Caribou Power Plant Has World's Largest Impulse Wheel, W. M. White. Jl. Electricity & Western Industry, vol. 47, no. 12, Dec. 15, 1921, pp. 465–466, 4 figs. Describes machinery installed in Caribou plant of Great Western Power Co., having normal capacity of 30,000 hp. each under 1008-ft. head, at 171 r.p.m.

Reaction. Hydraulic Reaction Turbines, D. J. McCormack. Elec. Jl., vol. 19, no. 1, Jan. 1922, pp. 11–16, 13 figs. Discusses runners, casing, bearings, shaft, gate mechanism, etc.

Recent Developments. High Speed Hydraulic Turbines (Om snabblöpande vattenturbiner). Teknisk Tidskrift (Mekanik), vol. 51, no. 12, Dec. 14, 1921, pp. 155–160, 18 figs. Discusses recent developments in design, especially profile, to increase degree of efficiency.

HYDRAULICS

Eddy Curves. New Method for the Determination of Eddy Curves (Nouvelle méthode pour la détermination des croubes de remous), E. Batiele. Le Génie Civil, vol. 79, nos. 23 and 24, Dec. 3 and 10, 1921, pp. 488–492 and 515–516, 7 figs. Reviews methods in use and develops formulas for an improved method which tests made show to be satisfactory.

Laboratory. The Hydraulic Laboratory, S. G. Roberts. Sci. Am., vol. 126, no. 1, Jan. 1922, pp. 10–11, 5 figs. Describes equipment and experimental work done at hydraulic laboratory at Petty's Island, Pa.

HYDROELECTRIC PLANTS

England. Nidd Valley Hydro-Electric Installation. Engineering, vol. 112, no. 2920, Dec. 16, 1921, pp. 817–818, 18 figs. partly on supp. plate and p. 824. Small hydroelectric plant built for purpose of supplying power for cranes, wire ropeways crushing plant, etc., to be employed in construction of new Scar House dam. See also Elec. Rev. (Lond), vol. 89, no. 2299, Dec. 16, 1921, pp. 810–812, 5 figs.; and Elec. Times, vol. 60, no. 1574, Dec. 15, 1921, pp. 531–533, 4 figs.; also Engineer, vol. 132, no. 3442, Dec. 16, 1921, pp. 639–641, 10 figs. partly on p. 650.

Silt-Removal Plants. Silt-Removal Plants for Hydroelectric Stations (Entsandungsanlagen nach Patent H. Dufour). Schweizerische Bauzeitung, vol. 78, nos. 25, 26 and 27, Dec. 17, 24 and 31, 1921, pp. 295–299, 310–312 and 323–325, 13 figs. Describes automatic and continuous silt-removal system patented by H. Dufour. Experience with sedimentation tanks, reconstructed according to described system, of hydroelectric plant supplying light and power to Santiago de Chile. Its employment in Swiss plants. Its effect on efficiency and economy of hydroelectric plants.

Storage Reservoirs. Hydroelectric Plants and Storage Reservoirs (Impianti idroelettrici e serbatoi), Aristide Zenari. Giornale dell'Associazione Nazionale degli Ingegneri Italiani, vol. 2, no. 14, Sept. 1, 1921, pp. 210–213, 1 fig. Discusses variation in water level and makes calculations.

I

ILLUMINATION

Calculation of Intensities. Illumination Calculations for Various Planes, J. H. Kurlander. Elec. Rev. (Chicago), vol. 79, no. 24, Dec. 10, 1921, pp. 885–887, 3 figs. Derivation of equation showing simple relations between illumination intensities, source candlepower, and dimensions that can be easily determined in the field or from room plans.

Factory. Factory Illumination. Eng. Production, vol. 3, no. 63, Dec. 15, 1921, pp. 570–571. Notes on installation of lighting systems. Discusses varieties of glass used for windows of industrial works, and different systems of artificial lighting, consisting of direct, semi-direct and indirect lighting.

INDICATORS

Steam-Engine. The Detection of Errors in the Steam-Engine Indicator. Power, vol. 55, no. 3, Jan. 17, 1922, pp. 103–105, 5 figs. Deals with most probable errors.

INDUSTRIAL MANAGEMENT

Factories. Technical Service at the Factory (Les Services d'études dans les usines), Emm. La Langlois. La Vie Technique et Industrielle, vol. 3, no. 26, Nov. 1921, pp. 132–133. Preparation of new installations; improvements in material, tools and processes; study of upkeep and repairs; filing of information and documents on all matters.

Gantt Charts. How a Manager Uses Gantt Charts, Frank W. Trabold. Management Eng., vol. 2, no. 1, Jan. 1922, pp. 28–30. Discusses use of the Gantt load, idleness-expense, and man-record charts, some things they disclosed, and their value to executive.

Inspection System. The Delco Inspection System—II and III. Machinery (Lond.), vol. 19, nos. 473 and 475, Oct. 20 and Nov. 3, 1921, pp. 71–75, 14 figs. and pp. 122–125, 12 figs. Typical examples of gaging fixtures used by Dayton Engineering Laboratories Co. in manufacture and inspection of company's product.

Planning. Departmental Collaboration, James Edgar. Eng. & Indus. Management, vol. 6, no. 24, Dec. 15, 1921, pp. 690–692. Explains scientific planning of output, which has become essential with introduction of quantity-producing methods, consequent upon development of automatic machine.

Process Charts. Process Charts and Their Place in Management, Frank B. and L. M. Gilbreth. Mech. Eng., vol. 44, no. 1, Jan. 1922, pp. 38–41 and 70, 4 figs. Device for visualizing process as means of improving it. Authors point out place of process chart in management and present established working data used successfully in numerous working installations for many years; also its simplicity, field of application, its relation to standardization, etc.

Production Order Quantity. Determining the Production Order Quantity, W. E. Camp. Management Eng., vol. 2, no. 1, Jan. 1922, pp. 17–18, 2 figs. Writer derives formula for determining production order quantity such that total cost per unit for

setting up plus interest on stores investment will be minimum.

Routing. A Term-Delivery System (Ein Terminabgabesystem), H. Hempel. Werkstattstechnik, vol. 15, no. 20, Oct. 15, 1921, pp. 600–605, 10 figs. Describes practical tried-out system for term delivery. Routing of work is carried out from a central office in close touch with all employees.

Service Department. Service Work As a Phase of Production, S. Harold Greene. Management Eng., vol. 2, no. 1, Jan. 1922, pp. 7–11. Outlines system of service work which, it is claimed, should be recognized as a necessary and integral part of production.

Stores Control. Some Notes on Stores Control. Eng. & Indus. Management, vol. 6, no. 24, Dec. 15, 1921, pp. 682–684, 2 figs. Notes on systematic recording and disposal of defective parts.

Small Factories. Management Problems of the Small Factory, Ernest Cordeal. Indus. Management, vol. 63, no. 1, Jan. 1922, pp. 43–49, 2 figs. Machines, tools and appliances.

Organization and Management of the Small Shop, E. W. Leach. Am. Mach., vol. 55, nos. 17, 19 and 22, Oct. 27, Nov. 10 and Dec. 1, 1921, pp. 671–673, 754–756 and 883–885. Oct. 27: Small shop office work; why bookkeeping is essential; classifications of entries; value of credit. Nov. 10: Going after business; cause and effect of readjustment; function of advertising. Dec. 1: Qualifications of successful executive; coöperation between producers and management; modern business ethics.

Tool-Engineering Department. How Tool Engineering Cuts Costs, Joseph Lannen. Indus. Management, vol. 63, no. 1, Jan. 1922, pp. 12–20, 9 figs. System of supervising jigs, fixtures, gages and other equipment. Describes methods that have given satisfactory results in process of ascertaining costs in tool-engineering department.

Workshops. Workshop Management (Le controle à l'atelier), C. B. Thompson. L'Outillage, vol. 234, no. 46, Nov. 17, 1921, pp. 1232–1233. Discusses scientific management and its various applications.

[See also TAYLOR SYSTEM; TIME STUDY.]

INDUSTRIAL ORGANIZATION

British Works. An Efficient Works System. Eng. Production, vol. 3, nos. 60, 61, 62, Nov. 24, Dec. 1, 8 and 15, 1921, pp. 493–498, 517–522, 539–544 and 557–562, 59 figs. Detailed description of successful organization and system in works of Barr & Stroud, Ltd., Glasgow, manufacturers of high-grade precision instruments.

Knitting Mill. The Organization of Knitting Mills, Carle M. Bigelow. Management Eng., vol. 2, no. 1, Jan. 1922, pp. 37–42, 5 figs. Solving problem of labor control.

INDUSTRIAL RELATIONS

Human Factor. The Human Factor in Industry—IV, Clarence H. Northcott. Indus. Management, vol. 63, no. 1, Jan. 1922, pp. 36–41. What industry owes workers as members of the community. Notes on wage principles; rate fixing; organization to guarantee fair wages; security against unemployment; work preparatory school; care for working conditions; vocational selection; etc.

Improvement of. Various Plans to Improve Industrial Relations, Ray Vance. Can. Foundryman, vol. 12, no. 8, Aug. 1921, pp. 32–35. Discusses human elements, stock selling plans, bonus plans, industrial democracy, shop committee plans, etc.

Workmen's Control. The Workman in Control (Le Contrôle ouvrier). La Métallurgie, vol. 53, no. 46, Nov. 17, 1921, pp. 2141–2142. Discusses attitude of workers, industrial democracy, consent of labor, etc.

INDUSTRIAL TRUCKS

Electric. The Electromobile. Motor Transport, vol. 33, no. 879, Jan. 2, 1922, p. 13, 3 figs. Describes a battery-propelled vehicle of the 1 and 2-ton and the 4 and 5-ton types, the latter having a four-wheel drive.

INTERNAL-COMBUSTION ENGINES

Compound. Compounding the Combustion Engine, Elmer A. Sperry. Mech. Eng., vol. 44, no. 1, Jan. 1922, pp. 27–32 and 74, 14 figs. Presents results of research by author extending over series of years, during which it is claimed that not only has high-pressure principle been thoroughly established, but all important requirements have been worked out, and an engine embodying practically all advantages has been subjected to long continuous runs.

Development. Internal Combustion Engine, Charles E. Lucke. Nat. Engr., vol. 25, no. 12, Dec. 1921, pp. 604–607. Rising importance of oil-injection type. Review of development.

Working Process. The Working Process of Internal-Combustion Engines (Die Darstellung des Arbeitsvorganges der Brennkraftmaschinen), P. Meyer. Zeit. des Vereines deutscher Ingenieure, vol. 65, no. 48, Nov. 26, 1921, pp. 1234–1238, 7 figs. Writer points to defects of temperature-entropy diagram for representation of heat movement in internal-combustion engines, and describes a method for making the same determinations without employment of the terms entropy and kilogram-molecule, by sole use of well-known technical measurement units, and of presenting them in uniform dependence on volumetric value.

[See also AIRPLANE ENGINES; AUTOMOBILE ENGINES; DIESEL ENGINES; OIL ENGINES; SEMI-DIESEL ENGINES.]

IRON

Electrolytic. Electrolytic Iron a Commercial Product, Bradley Stoughton. Iron Age, vol. 109, no. 1, Jan. 5, 1922, pp. 32–36, 5 figs. Eustis process compared with others. An ore instead of scrap as anode. Tests and properties, fields of usefulness.

IRON ALLOYS

Iron-Carbon. Study of Iron-Carbon Alloys (Zur Kenntnis der Eisen-Kohlenstofflegierungen), Rudolf Ruer. Zeit. für anorganische u. allgemeine Chemie, vol. 117, no. 4, July 27, 1921, pp. 249–261, 4 figs. Notes on solubility of cementite in molten iron; complete equilibrium between austenite, ferrite and graphite corresponding to equilibria of pearlite.

IRON AND STEEL

Production Cost, China. Cost of Iron and Steel Production in China. Colliery Guardian, vol. 122, nos. 3167 and 3168, Sept. 9 and 16, 1921, p. 714 and p. 818. Sept. 9: Gives tables of monthly figures of Hanyang and Penghsihu works and discussses them. Sept. 16: Gives cost of steel manufacture, and cost and labor. Concludes that cost of iron and steel production in China cannot be lowered unless there are better and cheaper means of transportation. From Peking Daily News.

L

LABOR

Eight-Hour Laws. The Eight-Hour Day (Autour de la journée de huit heures), Georges Lafond. L'Outillage, vol. 232, no. 44, Nov. 3, 1921, pp. 1165–1167. Discusses conditions in France and other countries, showing that it cannot be maintained.

Rules for Railway Shop Crafts. New Rules for Shop Crafts Issued by Labor Board. Ry. Mech. Engr., vol. 96, no. 1, Jan. 1922, pp. 9–16. Gives complete text of new rules, including special rules for each craft. Provisions made more elastic; rights of minorities recognized; many old rules retained.

LABORATORIES

Research. Finding the Better Way—III, Charles E. Ruby. Indus. Management, vol. 63, no. 1, Jan. 1922, pp. 26–29, 3 figs. How research laboratories assist business. Users of industrial laboratories.

LATHES

Capstan. A 5$^1/_2$-Inch Capstan Lathe. Engineer, vol. 132, no. 3443, Dec. 23, 1921, pp. 684–685, 4 figs. Describes new design of lathe by Pollock & Macnab, Ltd., Bredbury, England, which is said to be much more powerful than lathes of this size usually are.

Turret. Turret Lathe Tooling, I. F. Yeoman. Machy. (N. Y.), vol. 28, no. 5, Jan. 1922, pp. 356–358, 4 figs. Equipment for machining differential gear housings on foster turret lathes.

LEAD ALLOYS

Frary Metal. The Electrolytically Produced Calcium-Barium-Lead Alloys Comprising Frary Metal, William A. Cowan, L. D. Simpkins and G. O. Hiers. Chem. & Met. Eng., vol. 25, no. 26, Dec. 28, 1921, pp. 1181–1185, 13 figs. Equilibrium diagram and microstructure of barium-lead and calcium-lead alloys. Ternary alloy hardens and strengthens on aging; is hard at moderate temperature; can be melted without change in analysis, and is a very fine bearing metal. Paper, slightly condensed, read before Am. Electrochem. Soc.

LIFTING MAGNETS

Use in Workshops. Lifting Magnets and Their Use in Workshops (Die Lasthebemagnete und ihre Anwendung im Werkstättenbetriebe), Richard Hänchen. Betrieb, vol. 4, no. 5, Dec. 10, 1921, pp. 157–162, 13 figs. Discusses their useful field, operation and efficiency, and describes newest types.

LIQUIDS

Corrosive, Handling. Anti-Corrosive Chemical Engineering Plant. Canadian Chemistry and Metallurgy, vol. 5, no. 12, Dec. 1921, pp. 341–342, 2 figs. Some English chemical equipment designed for special service in handling acids and corroding liquids.

LOCOMOTIVES

Design. Modern Locomotive Engine Design and Construction—LXXVI. Ry. Engr., vol. 42, no. 503, Dec. 1921, pp. 458–463, 7 figs. Practical considerations affecting production of an economical form of coupling rod.

Electric. See ELECTRIC LOCOMOTIVES.

Missouri and Northern Pacific. Operating Capacity Increased With Modern Motive Power. Ry. Rev., vol. 69, no. 25, Dec. 17, 1921, pp. 817–821, 8 figs. Describes Mikado, Mountain, and Pacific types, constructed by Am. Locomotive Co. for Missouri and Northern Pacific roads.

Mountain Roads. Shay Geared Locomotives for Mountain Roads. Ry. Age, vol. 71, no. 25, Dec. 17, 1921, pp. 1198–1210, 4 figs. 150-ton Shay for Greenbriar, Cheat & Elk R. R. High sustained tractive effort compared with Mikados.

Rebuilding. Rebuilding Old Locomotives, Carl B. Smith. New England Railroad Club, Dec. 13, 1921, pp. 207–214 and (discussion) 215–228. Discusses replacing of boilers, superheater equipment, cylinders, valve gears, frames, automatic fire doors, and other parts.

Superheater. Locomotives of the Pacific Type of the Midi Company, France (Note sur les locomotives Pacific à deux cylindres à simple expansion et surchauffe de la Compagnie des Chemins de Fer du Midi), M. Leboucher. Révue Générale des Chemins de Fer et des Tramways, vol. 40, no. 11, Nov. 1921, pp. 291–303, 7 figs., partly on supp. plate. Superheater, two cylinder twin-action type. Complete specifications and data.

LUBRICANTS

Reclamation and Distribution. Supplying Oil to 2,000 Automatic Screw Machines, E. C. Henn. Am. Mach., vol. 56, no. 1, Jan. 5, 1922, pp. 4–7, 10 figs. Oil pumped from tank cars to storage tanks; centrifugal machines separate used oil from chips; elaborate system of reclamation and distribution.

Viscosity and Friction. Viscosity and Friction, Winslow H. Herschel. Soc. Automotive Engrs. Jl., vol. 10, no. 1, Jan. 1922, pp. 31–41, 2 figs. Discusses viscosity effect in complete-film-lubrication régime; viscosity estimation at one temperature from observed viscosity at another temperature; friction testing of bearing metals; oiliness of lubricants; oil-friction testing machines; etc.

LUBRICATING OILS

Steam-Turbine. Essential Qualities of Oil for Steam Turbine Lubrication, J. Y. Dahlstrand. Elec. Rev. (Chicago), vol. 79, no. 21, Nov. 19, 1921, pp. 770–772, 3 figs. Definition of viscosity of oil; tests required to determine quality of oil; auxiliary oil pump and its operation and use.

The Viscosity of Steam-Turbine Oils, V. M. Hatch. Power, vol. 54, no. 26, Dec. 27, 1921, pp. 1011–1012. Factors controlling friction in bearings. Viscosity at operating temperature is said to be most important consideration.

M

MACHINE GUNS

Browning .50-Caliber. The Super-Machine Gun, Herbert O'Leary. Army Ordnance, vol. 2, no. 9, Nov.-Dec. 1921, pp. 129–132, 7 figs. Describes the Browning .50-caliber machine gun and its successful development.

MACHINE SHOPS

British. Famous British Works. Eng. Production, vol. 3, nos. 64 and 65, Dec. 22 and 29, 1921, pp. 578–580, 6 figs. and 602–604, 4 figs. Dec. 22: Describes Siemens Works, Stafford, of the English Elec. Co., Ltd., for manufacture of medium sizes of electrical equipment, particularly rotary converters for industrial purposes and electric traction, and switchgear of all kinds. Dec. 29: The Hoffmann Mfg. Co., Ltd., Chelmsford, for manufacture of ball and roller bearings.

MACHINE TOOLS

Drives. The Driving of Machine Tools, Hubert Bentley. Eng. & Indus. Management, vol. 6, no. 24, Dec. 15, 1921, pp. 688–689. Practical advice on efficient driving of modern machine tools. Deals with increased employment of chain and direct-gear drive in transmitting power, and advent of direct drive from lineshaft to single-pulley all-gear-driven machine.

Feeds and Speeds. Feeds and Speeds as Production Factors, Albert A. Dowd and Frank W. Curtis. Machy. (N. Y.), vol. 28, no. 5, Jan. 1922, pp. 381–383, 5 figs. Importance of recording; installing a system of and setting speeds and feeds; savings made possible by increasing rate of feed on a lathe; savings effected by change of tools.

MACHINERY

Special and Automatic. When Is It Economical to Install Special and Automatic Machinery? A. L. DeLeeuw. Management Eng., vol. 2, no. 1, Jan. 1922, pp. 19–24, 1 fig. Includes chart showing various conditions met in grouping special machinery. Notes on determining costs under part-time operation; figuring value of machinery; single-purpose machines; operating automatic machinery in cycles; etc.

MALLEABLE CASTINGS

Foundry Problems. Pertinent Facts Concerning Malleable-Iron Castings, Enrique Touceda. Soc. Automotive Engrs. Jl., vol. 10, no. 1, Jan. 1922, pp. 53–61, 12 figs. Discusses foundry difficulties; casting defects; shrinkage and machinability; improvements in annealing-oven construction and operation.

MANGANESE STEEL

Electric. Manganese Steel Made in Electric Furnace, Larry J. Barton. Iron Age, vol. 109, no. 1, Jan. 5, 1922, pp. 4–8 and 109, 11 figs. Discusses melting practice for castings. Use of manganese steel scrap. Deoxidizing with manganese ore Heat treatment.

Welding. Welding Manganese Steel, H. R. Pennington. Welding Engr., vol. 12, Dec. 1921, pp. 21–23 and (discussion) 23–24, 2 figs. Frogs and crossing layouts put in service at a fraction of cost of new installation. Gives table showing effect of varying quantities of manganese and carbon on physical quality of steel. Discusses arc welding methods. Paper read before Am. Welding Soc.

MARINE STEAM TURBINES

Blading Failures. Low Pressure Turbine Blading Failures in Destroyers, D. F. Ducey. Jl. Am. Soc. Naval Engrs., vol. 33, no. 3, Aug. 1921, pp. 512–540, 39 figs. The turbines are of the impulsive type having five rows of moving blades. The first and second are of monel metal, the third, fourth and fifth of chrome-vanadium and chrome-nickel steel Describes failures in detail and gives illustrations.

MATERIALS

Thermal Conductivity of Wearing. Thermal Conductivity of Some Wearing Materials, Emily S. Rood. Physical Rev., vol. 18, no. 5, Nov. 1921,

pp. 356-361. Results of measurements made with samples of woolen, cotton, and silk materials

METALS

Colloidal State. Colloidal State in Metals and Alloys—I, Jerome Alexander Chem & Met Eng., vol. 26, no. 2, Jan 11, 1922, pp 54-58 Molten metal. Shows that many of important phenomena of metals and alloys are due to colloidal state of subdivision, and that portion of the metal or alloy tends to remain in the colloidal state and exert a powerful influence upon physical properties of final solid magma.

Electro-deposition. The Electro-Deposition of Metals—VIII, W E Hughes Beama, vol. 9, no 6, Dec 1921, pp. 555-562 Discusses electrodeposition of lead Applications, properties, lead-plating solutions, and macrostructure

Fatigue. Fatigue of Metals Under Repeated Stress, Moore and Kommers Chem. & Met Eng., vol. 25, no. 25, Dec 21, 1921, pp 1141-1144, 6 figs. Results of experiments. Carbon steels will not fail by "fatigue" if stressed below a definite amount, quickly determined by measuring heat generated in specimen during test.

Grain Structure. Grain Structure in Metals (Ueber Faserstruktur bei Metallen), Margarete Ettisch, M. Polanyi and K Weissenberg Zeit fur Physik, vol. 7, no 3, Nov 3, 1921, pp. 181-184, 4 figs. Investigation of hard-drawn copper and tungsten wires, results of which show crystallographic directions in which wires are grained.

Metallographic Testing. Metallographic Testing. U S. Bur of Standards Circular, no 42, Aug 29, 1921, 11 pp., 4 figs. Study of fundamental conditions, structure, constitution, and treatment of metals and alloys. Discusses different lines of metallographic testing carried out by Bur of Standards.

Structure. Structure and Related Properties of Metals, U. S. Bur. Standards Circular, no. 113, Sept. 7, 1921, 104 pp., 71 figs. Discusses general nature of structure of metals, methods for revealing it, and dependence of properties of metal as a whole upon its structural features. Describes methods in use for revealing chemical unhomogeneity, crystalline heterogeneity, physical unsoundness, and mechanical nonuniformity. Discusses principles underlying action of etching reagents; conditions affecting structure, chemical composition, application of heat, and mechanical working of metal; and dependence of mechanical properties and chemical behavior upon structure condition of material.

Surface Flaws. Influence of Surface Flaws on Strength of Metals, Horace C. Knerr. Automotive Industries, vol. 45, no. 25, Dec. 22, 1921, pp. 1216-1217, 6 figs. Shows that surface flaws have a pronounced effect upon metals subjected to fatigue through repeated stresses, but that such flaws do not always decrease strength under constant load conditions.

Testing. Testing Metal by Repeated Stress, H. F. Moore and J. B. Kommers. Iron Trade Rev., vol. 69, no. 25, Dec. 22, 1921, pp. 1623-1630, 7 figs.; also Eng. News-Rec., vol. 88, no. 2, Jan. 12, 1922, pp. 76-78, 3 figs. Fatigue investigation is broadened to include variety of steels and several heat treatments. Results show definite relation between Brinell hardness and endurance limit. Rise of temperature test used to predict limit. (Abstract.) Bul. no. 124. Engineering Experiment Station, University of Illinois.

METRIC SYSTEM

English System vs. A Digest of "The Metric versus the English System of Weights and Measures." Nat. Indus. Conference Board, Special Report No. 20, Dec. 1921, 11 pp. Presents facts and arguments on whether metric system should be substituted for English system of weights and measures in the United States.

MILLING CUTTERS

Backed-Off. Backed-Off Milling Cutters (Ueber hinterdrehte Fräser), Paul Zietung. Werkstattstechnik, vol. 15, no. 20, Oct. 15, 1921, pp. 593-595, 32 figs. Notes on production of backed-off profile cutters with a forming tool and different separate tools in various relief stages: control of backed-off milling cutters. Discusses copying with backed-off milling cutters.

Sharpening. How to Sharpen Milling Cutters, Fred B. Jacobs. Abrasive Industry, vol 2, no. 12, Dec. 1921, pp. 395-401, 19 figs. Cutter grinding operations are expedited by using a machine designed for the purpose; form cutters require careful attention.

MILLING MACHINES

Manufacturing Operations. Manufacturing Operations on Milling Machines, Robert Mawson. Am. Mach., vol. 55, no. 25, Dec. 22, 1921, pp. 996-997, 10 figs. Special toolholders for facing four-step cones. Fixtures and tools for machining milling machine heads. A unique angle-facing fixture.

MOLDING MACHINES

Modern Types. The Present Status of Molding Machine Construction—I (Der heutige Stand des Formmaschinenbaues), U. Lohse, Zeit. des Vereines deutscher Ingenieure, vol. 65, no. 48, Nov. 26, 1921, pp. 1220-1223, 17 figs. Deals with hand-molding machines, including machines with lifting carriages, stripping-plate machines, and turnover-type machines.

Rollover. Rollover Jarring Machines (Der Gutmannsche Umrollrüttler), U. Lohse. Giesserei-Zeitung, vol. 18, no. 32, Nov. 15, 1921, pp. 423-424, 1 fig. Machine constructed by A. Guttmann Machine Constr. Corp., Hamburg, is said to differ from American types in that all the movements (jarring, rolling over and taking out) are effected by a single pneumatic cylinder by means of a single regulating cock.

MOLDING METHODS

Flour-Mill Rolls. Molding and Casting Chilled Flour-Mill Rolls, G. O. Vair. Can Foundryman, vol 12, no. 8, Aug 1921, pp 20-21 and 25, 5 figs Designs for molds; casting; machining.

MOLYBDENUM STEEL

Annealing. Constituents Observed in Tungsten and Molybdenum Steels (Constituants observés dans les aciers au tungstène et les aciers au molybdène) Albert Portevin. Révue de Métallurgie, vol 18, no 11, Nov. 1921, pp. 713-716, 6 figs. Effects of annealing and subsequent very slow cooling on structure. Paper read before Iron & Steel Inst., Paris.

MOTOR TRUCKS

Manufacturing Methods. Manufacturing Parts of Northway Trucks, Robert Mawson. Am. Mach., vol 56, no 3, Jan 19, 1922, pp 101-103, 10 figs. Work on pistons and connecting rods; turning and inspecting camshafts; crankshaft balancing; fixture for assembling chassis; pressing on rubber tires.

MOTORCYCLES

Single-Cylinder Solo. The Development of the Single-Cylinder Solo Motor Cycle, H. D. Teage. Automobile Engr., vol. 11, no. 156, Nov. 1921, pp. 382-386, 12 figs. Distinguishes between the luxurious go-anywhere touring mount, the purely sporting machine, and the machine for the multitude. Discusses weight, valve gear, two-cycle engines, cooling, lubrication, ignition, transmission, etc Paper read before Instn. Automobile Engrs.

N

NOZZLES

Measuring Pulsating Flow. The Use of Nozzles in Measuring Pulsating Flow. Chem. & Met. Eng., vol. 26, no 1, Jan. 4, 1922, pp. 32-34, 3 figs. Discusses errors resulting from use of nozzles for measuring differential pressure unless the flow curve is known as a function of time.

O

OIL ENGINES

High-Compression. The Recent Development of High-Compression Oil Engines Without Air Pumps, Especially As Small Oil Engines (Die neuere Entwicklung der Hochdruckölmaschine ohne Luftpump, insbesondere als Kleinölmaschine), F. Modersohn. Oel- u. Gasmaschine, vol. 18, nos. 9, and 11, Sept. and Nov. 1921, pp. 140-142, and 169-173, 2 figs. Deals only with such engines whose practicability has been demonstrated, which are divided into three groups, namely, those operating with pure pressure injection; with combustion-chamber action; and with eddy production.

Manufacturing Methods. Cutting Costs in a Crude-oil Engine Manufactory. Machy. (Lond.), vol. 19, no. 481, Dec. 15, 1921, pp. 315, 11 figs. Reviews methods employed by Vickers-Petters, Ltd., Ipswich, including machining component parts, operations on cylinder casing and cylinder liners, elimination of non-productive machine time, etc.

OIL FUEL

Burning. The Burning of Oil Fuel and the Arrangement of Machinery Necessary, together with Observations and Comments Drawn from Actual Conditions, A. Keens. Trans. Inst. Mar. Engrs., vol 33, Oct. 1921, pp. 337-363 and (discussion) 363-375, 12 figs. Discusses advantages of fuel oil; storage spaces; oil fuel pumps; piping, holders and burners; furnaces and combustion chambers; pumping arrangement; etc.

Glass Industry. The Application of Oil Fuel in the Glass Industry. Jl. Soc. Glass Technology, vol 5, no. 19, Oct. 1921, pp. 286-300 and (discussion) 300-307. Symposium. Comparison with gas firing.

Injection and Combustion. Injection and Combustion of Fuel-Oil—VI and VII, C. J. Hawkes. Motorship, vols. 6 and 7, nos. 10 and 2, Oct. 1921 and Jan. 1922, p. 820, 4 figs. and p. 34, 6 figs. Experiments with solid-injection and air-blast in marine Diesel engines.

Mexican. The Production and Combustion of Mexican Fuel Oil—VIII, J. M. Pettinbell and J. R. Carlson. Combustion, vol. 5, no. 6, Dec. 1921, pp. 254-257, 6 figs. Discusses economy in oil burning operation.

Steam Generation. Liquid Fuel and Its Application for Steam Generation, J. H. Anderson. Inst. of Mar. Engrs. Trans., vol. 33, Dec. 1921, pp. 521-563 and (discussion) 563-568, 27 figs. Discusses fractional and continuous distillation, and use of fuel oil. Describes a number of oil fuel heaters and systems of fuel-oil burning.

Sulphur in. Effects of Sulphur in Fuel Oil, Allen F. Brewer. Power, vol. 55, no. 2, Jan. 10, 1922, pp. 50-51. States that presence of sulphur is detrimental, but its deteriorating effect can be largely avoided by adopting proper precautions.

OILS

Vegetable, Machines for Producing. Machinery for Vegetable Oil Prodiction. Eng. Rev., vol. 35, no. 6, Dec. 1921, pp. 182-187, 8 figs. Reviews development of these machines and compares the various designs.

OPEN-HEARTH FURNACES

Fuels Used. Fuels Used in Open Hearth Practice, Edwin F. Cone Iron Age, vol 108, no. 25, Dec. 22, 1921, pp 1589-1591 Analysis of 1920 ingot and castings production. Producer gas chiefly employed for ingots and oil for castings. Results of answer to questionnaire sent to producers of open-hearth steel ingots and steel castings.

OXY-ACETYLENE WELDING

Bronze Condenser Sheets. Bronze Condenser Sheets, H. I. Walsh. Welding Engr., no 12, Dec. 1921, pp 27-28 and 40, 7 figs. Gas welding gives practical solution of problem arising from increase in size of ships. Paper read at Internat Acetylene Assn Convention

P

PIPE, STEEL

Hammer-Welded. Hammer-Welded Steel Pipe—How It Is Made and Wherein It Excels. Raw Material, vol. 4, no 11, Nov. 1921, pp. 384-391, 11 figs. Discusses advantages over butt-weld and lap-weld methods, and methods used by Nat. Tube Co.

PIPE, WROUGHT-IRON

Chart for. Wrought Pipe Data Sanitary & Heat. Eng., vol. 96, no. 14, Dec. 30, 1921, p. 395. Chart containing valuable information for the sanitary and heating engineer.

PISTONS

Machining Castings and Rings. How a British Foundry Specializes, H. Cole Estep. Foundry, vol 49, no. 22, Nov. 15, 1921, pp. 879-887, 22 figs. Describes English methods of making piston castings and pots for piston rings.

PLANERS

Testing. Planing Machine Studies. Engineering, vol. 112, no. 2922, Dec. 30, 1921, p. 886. Results of experimental work carried out in Germany by G. Schlesinger on a horizontal planing machine, driven by electric motor running at 1460 r.p.m. with toothed gear and belting. Various improvements were tested and it was possible to greatly reduce power absorbed and almost completely overcome power fluctuations. Translated from pamphlet by G. Schlessinger and M. Kurrein.

POWER

Costs. How to Follow Up Power Costs—III, N. A. Craigue. Indus. Management, vol. 63, no. 1, Jan. 1922, pp. 55-59, 1 fig. Various methods of distribution. Meters may be used to actually measure power as consumed; cost rate applied, and final cost obtained is charge against product.

POWER PLANTS

Design. Developments in Power Station Design. Engineer, vol. 132, nos. 3441, 3443 and 3444, Dec. 9, 23 and 30, 1921, pp. 613-614, 5 figs., partly on supp. plate.; 668-669, 3 figs.; 702-704, 10 figs. Dec. 9: Describes extensions being made to boilerhouse of the Neasden power station of Metropolitan Ry. by John Thompson Water-Tube Boilers, Ltd., Wolverhampton. Dec. 23: 12,000-kw. turbo-generator installed at Neasden power station, and other important additions. Dec. 30: Application of air heaters to central-station boilers.

Modern European Tendencies in Power-Plant Design, A. W. H. Griepe. Power, vol. 55, no. 2, Jan. 10, 1922, pp. 54-56. European tendency is now to supply large cities at high voltage from large generating stations near mines, and gradually to shut down small, inefficient local plants. Notes on modifications in boiler proportions, types of boilers in use, boiler tubes and superheaters, economizers, stokers, cinder and soot disposal, preheating of air, use of low-grade fuels, etc. The Bone-Schnabel surface-combustion process in Germany. Only horizontal types of turbines used.

Maxim Silencers, Use of. The Maxim Silencer in the Power Plant. Power, vol. 55, no. 3, Jan. 17, 1922, p. 91, 3 figs. Describes use of such silencers, patents for which are now pending, as power-plant apparatus, for application to exhausts of oil and gas engines, oil- and gas- engine suctions, compressed-air unloaders, unaflow-engine exhausts, steam safety valves, air hoists, steam and air discharges from special apparatus.

Progress in 1921. The Year's Progress in the Power Plant Field. Power, vol. 55, no. 1, Jan. 3, 1922, pp. 2-14, 11 figs. Boiler efficiencies of 90 per cent when burning pulverized coal, seven notable steam plants put into operation, unusual interest in hydroelectric development, 220,000-volt electric power equipment, are some of outstanding features of 1921.

PRESSES

Hydraulic and Hand-Forcing. Hydraulic and Hand Forcing Presses in a Locomotive Shop, J. V. Hunter. Am. Mach., vol. 56, no. 3, Jan. 19, 1922, pp. 108-109, 5 figs. Horizontal press for forcing brasses in boxes. Method of using air pumps for boosting pressures. Self-contained portable press.

Fixtures. Some Examples of Fixtures Used on Profiling Machines, J. M. Henry. Am. Mach., vol. 55, no. 26, Dec. 29, 1921, pp. 1040-1043, 11 figs. Points out that with suitable fixtures, machines may be used for many different operations; and two or more operations may be preformed at one setting.

PULVERIZED COAL

Air Furnaces. Apply Powdered Coal to Air Furnace, Pat Dwyer Foundry, vol. 49, no. 24, Dec. 15, 1921, pp. 955-962, 15 figs. Malleable-iron melting furnaces and annealing ovens have been converted

from hand-firing to use of powdered coal without involving radical changes in design.

Application to Boilers. Application of Pulverized Coal to Boilers, J. W. Fuller. Trans. Am Inst. Min & Metallurgical Engrs., no. 1106–C, 1921, 4 pp Gives a few instances of many successful installations burning pulverized coal that were made under various types of boilers and using many fuels. Abstract of paper in Min. & Metallurgy, no 180, Dec. 1921, pp 35 36.

Metallurgical Furnaces. Powdered Fuel, J. S. Atkinson. Iron & Coal Trades Rev., vol 103, no. 2805, Dec. 2, 1921, p. 802. Recent developments in connection with firing of metallurgical furnaces. Relative costs of gas firing and powdered fuel firing, cost of powdering, etc. (Abstract.) From Fuel Economy Rev.

Preparation and Combustion. The Preparation, Transportation, and Combustion of Powdered Coal, John Blizard. Canada Dept. of Mines, no. 564, 1921, 131 pp., 42 figs. Discusses distribution; feeder, mixers and burners; advantages and disadvantages; use for steam raising, costs of preparing and delivering to furnace; operating and repair costs; etc.

Small-Plant System. Pulverized-Coal System for Small Plants. Power, vol. 54, no. 26, Dec. 27, 1921, pp. 1016–1017, 2 figs. System consisting of self-contained crusher and blower allows pulverized coal to be used in small plants.

Turbo Pulverizer. The Turbo Pulveriser. Iron & Coal Trades Rev., vol. 103, no. 2807, Dec. 16, 1921, p. 877, 1 fig. Describes apparatus built by The Powdered Fuel Plant Co., Ltd., Lond., which is a pulverizing mill and fan combined.

PUMPING PLANTS

Hydroelectric Reservoirs. Pumping Plants for Water-Power Reservoirs (Les installations d'accumulation hydraulique par pompage), Jacques Godin. Révue Générale de l'Électricité, vol. 10, no. 24, Dec. 17, 1921, pp. 881–887, 7 figs. Discusses pumping plants for supplying additional water power to hydroelectric plants which desire to increase beyond their capacity, and gives successful examples in France and Italy.

PUMPS

Mammoth. Mammoth Pumps Eng. Progress, vol. 2, no. 12, Dec. 1921, pp. 277–278, 3 figs. Describes construction and operation of the pump and its application to raising water, chemical liquids, and solid substances that can be moved in currents of fluids.

PUMPS, CENTRIFUGAL

High-Pressure. The Operation of High-Pressure Centrifugal Pumps (Die Betriebsweise der Hochdruck-Zentrifugalpumpen). Wärme- u. Kälte-Technik, vol. 23, no. 22, Nov. 15, 1921, pp. 253–257, 8 figs. Includes table giving results of tests with a 3-stage high-pressure centrifugal pump for raising 2000 liters of water per minute to height of 112 m., directly coupled with a 75-hp. asynchronous motor with 1480 r.p.m. at 50 periods. Points out advantages and useful field of centrifugal pumps.

Parallel Operation. Operating Pumps or Fans in Parallel, J. C. Hobbs. Power, vol. 55, no. 2, Jan. 10, 1922, pp. 58–60, 6 figs. Discusses problems encountered in parallel operation of centrifugal pumps and explains why pumps must have correct characteristics.

PYROMETERS

Radiation. A New Radiation Pyrometer for the Measurement of High Temperatures (Ein neues Strahlungspyrometer zur Messung hoher Temperaturen), Georg Keinath. Elektrotechnische Zeit., vol. 42, no 48, Dec 1, 1921, pp. 1384–1387, 10 figs. With temperatures exceeding 1200 deg. cent. the wear of thermocouple armors is said to be considerable, so that it appears advisable to carry out measurements with radiation pyrometers. A new construction type and its properties are described.

PYROMETRY

Liquid-Fuel-Fired Boilers. Pyrometry of Boilers Fired with Liquid Fuel, E. C. Reed Eng. & Indus. Management, vol. 6, no. 26, Dec. 29, 1921, pp. 743–746, 4 figs. Describes the Foster fixed focus pyrometer and its application. Writer claims that expense of installation of pyrometer system may be saved many times over in year.

R

RAILS

Reclaiming Worn-Out. Worn-Out Rails –Their Resurrection from Uselessness to Usefulness. Raw Material, vol 4, no. 11, Nov. 1921, pp. 392–395, 11 figs. Describes operations at Sweet's Steel Co.'s rail reclamation plant, Williamsport, Pa.

Sink-head Ingot Rolling. Sound Steel in Rail Manufacture, Cecil J. Allen. Ry. Engr., vol. 42, no. 503, Dec 1921, pp 468–470, 3 figs. Comparison of results obtained by Pennsylvania Railroad with rails rolled from sink-head and ordinary ingots, respectively.

Sorbitic Steel. Wear of Railroad and Street Car Rails (L'Usure des rails de chemins de fer et de tramways), J. Gouttier Révue Universelle des Mines, vol. 11, no. 5, Dec. 1. 1921, pp. 524–513, 12 figs. Describes Sandberg process of producing sorbitic steel and its successful application to rails.

The Latest in Steel Rails, Frederic C. Carl. Sci Am., vol 126, no 1, Jan. 1922, p. 44. Notes on sorbitic steel rail manufactured according to Sandberg process, which is said to double life of rail while increasing cost only by 20 per cent.

Wear. Causes of Premature Wear of Rails (Les causes de l'usure prématurée des rails). Le Génie Civil, vol. 79, no. 21, Nov. 19, 1921, pp. 429–433, 26 figs. Discusses cracks, fissures, segregation, etc., in rails; effect of tempering, and of natural wear.

RAILWAY CONSTRUCTION

Canada. Development of Canadian Railway Construction, H. K. Wicksteed. Can. Engr., vol. 42, no. 1, Jan. 3, 1922, pp. 104–108. Describes early trade routes and economic conditions which resulted in construction of railways in Canada. Problems solved by engineers when locating trans-continental road. Paper before Am. Assn. for Advancement of Sci.

Grade Reduction. Justifying Expenditures for Grade Reductions, George J. Ray. Ry. Age, vol. 71, no. 26, Dec. 24, 1921, pp. 1243–1250, 5 figs. Shows that the construction of the Clarks Summit-Hallstead line is fully warranted by operating results. (Abstract.) Paper read before Western Soc. Engrs.

RAILWAY ELECTRIFICATION

Advantages. Railway Electrification, Vincent L. Raven. North-East Coast Instn. Engrs. & Shipbuilders, advance paper, no. 3195-P for meeting, Dec. 16, 1921, 24 pp., 9 figs., partly on supp. plate. Deals with advantages which may result from substitution of electric for steam locomotive operation. See also Engineer, vol. 132, nos. 3443 and 3444, Dec. 23 and 30, 1921, pp. 673–674 and 711, 713, 5 figs., partly on supp. plate.

Steel Plant. Electrification of Steel Plant Railroad, R. B. Gerhardt. Iron Age, vol. 108, no. 26, Dec. 29, 1921, pp. 1663–1666. Difficulties are said to include protection of third rail from hot metal spills. Saving in cost 50 per cent. Investment offset by low operating cost. Paper presented before Assn. Iron & Steel Elec. Engrs.

Superpower Plan. Electric Traction Proposed for 11 Railroads. Ry. Elec. Engr., vol. 12, no. 11, Nov., 1921, pp. 409–414, 9 figs. Discusses Superpower Survey report transmitted to the president containing plan providing for the interconnection of a large number of existing plants. By consolidating power supply, electric operation could be made to show saving of 14 per cent.

RAILWAY OPERATION

North Eastern Railway. Surveys, Diagrams and Other Records Prepared by the Engineer's Department of the North Eastern Railway, Conrad Gribble. Ry. Gaz., vol. 35, no. 23, Dec. 2, 1921, pp. 841–848, 7 figs., partly on supp. plate. Line and siding diagrams as substitutes for surveys. Coördination of field work in measuring distances for statistical, operating and commercial purposes. Systematic recording of strength of bridges. Percentage system for recording equivalent weights of locomotives.

Train Dispatching. Management of Single Track Lines in Great Britain (Note sur l'exploitation des lignes a voie unique dans le Royaume-Uni). Review Génerale des Chemins de Fer et des Tramways, vol. 40, no. 11, Nov. 1921, pp. 304–318, 14 figs. Discusses ticket, tablet, and token systems of train dispatching, and the various apparatus for exchanging used in connection with them.

RAILWAY SHOPS

Montreal, Can. A Railroad Shop Organized for Efficiency. Machy. (N. Y.), vol. 28, nos. 4 and 5, Dec. 1921, and Jan. 1922, pp. 291–293 and 389–392, 8 figs. Description of Angus shops of Can. Pac. Ry. Co., Montreal, Canada, and equipment and methods employed.

RAILWAY SIGNALING

Interlocking. New Interlockings at Jacksonville Terminal, C. J. Kelloway, Ry. Signal Engr., vol. 14, no. 12, Dec. 1921, pp. 462–468, 18 figs. Developments in the construction of a large electro-pneumatic and two electro-mechanical plants with inter-connecting circuits.

RAILWAY SWITCHES

Electric. Electrically Operated Equipment for Car Handling, R. M. Kintzing. Elec. Rev. (Chicago), vol. 79, no. 21, Nov. 19, 1921, pp. 773–775, 6 figs. Interlocking and limit control switches employed to assure proper sequence in cycle of movements; great saving in labor and increase in plant capacity secured by electrical operation.

RAILWAYS

China. The Peking-Suiyuan Railway of China. Sci. Am., vol. 126, no. 2, Feb. 1922, pp. 116–117, 8 figs. Description of road surveyed, constructed and operated entirely by Chinese.

Development 1921. General Railroad Developments During the Year. Ry. Age, vol. 72, no. 1, Jan. 7, 1922, pp. 9–154, 89 figs. Articles on regulation of securities, labor situation, federal valuation, railroad accounts with the government, profit of railroads from lower material costs, recent tendencies in locomotive development, special types of cars introduced in 1921, maintenance of way, cutting freight loss and damage claims, accounting, equipment conditions, electrical developments, repair-shop and enginehouse development, chronological review of year's activities. Also contains articles on railway statistics, including locomotive, freight-car and passenger-car market.

Monorail Suspended Line. Monorail Suspended Railroad Tracks and Canal-Boat Haulage (Système de voies suspendues monorails et systeme de halage des bateaux), M. Mahl. Bul. de la Société Française des Électriciens, vol. 1, no. 7, July 1921, pp. 337–368, 13 figs. Discusses a projected monorail line from Paris to Nice according to the Barmen-Elberfeld system, but with maximum speed of 300 km. per hr., also power transmission and boat haulage as side issues.

REFRACTORIES

Resistance. Resistance Tests on Refractory Products under Load at Different Temperatures, V. Bodin. Quarry & Surveyors' & Contractors' Jl., vol. 26, no. 297, Nov. 1921, pp. 438–440, 3 figs. Results of tests, and table of crushing loads in kg.-cm. (Abstract.) Paper read before Ceramic Soc.

REFRIGERATING MACHINES

Carbon-Dioxide. Carbon-Dioxide Refrigerating Machine, H. J. Macintire. Power, vol. 55, no. 1, Jan. 3, 1922, pp. 24–26, 3 figs. Relative advantages of carbon dioxide *vs.* ammonia as refrigerating medium, in which pressure range, cooling-water limitations, horsepower per ton, relative size and construction are considered.

Tests on a Carbonic-Acid Refrigerating Machine with Additional Compression under High Condenser Pressures (Versuche an einer Kohlensäurekältemaschine mit Zusatzkompression bei hohen Kondensatordrücken), R. Plank. Zeit. für die gesamte Kälte-Industrie, vol. 28, no. 11, Nov. 1921, pp. 157–162, 3 figs. Writer refers to process described by him in previous issue of this journal (p. 189, 1913), by use of which, it was claimed, considerable increase of refrigeration output and economy in cold carriers with low critical temperature (CO_2, N_2O), could be effected under poor cooling-water conditions and correspondingly high condenser pressure. Present article gives brief description of process and results of practical test recently carried out demonstrating its practicability.

REFRIGERATING PLANTS

Temperatures and Pressures. Working Temperatures and Pressures in the Refrigeration Plant, W. H. Motz. Power, vol. 54, no. 26, Dec. 27, 1921, pp. 1005–1007, 3 figs. Notes on suction pressures and temperatures; discharge temperatures and pressures; uses of thermometers.

RESEARCH

Fan Industry. Relation of Research to the Fan Industry. Am. Soc. Heat. & Vent. Engrs. Jl., vol. 27, no. 9, Dec. 1921, pp. 873–881. Research in the Heating and Ventilating Field, by J. I. Lyle; and Research as a Business Proposition, by F. R. Still.

ROLLING MILLS

Adjustable-Speed Motors. Adjustable Speed With Motor Driven Mills, K. A. Pauly. Iron Age, vol. 108, no. 25, Dec. 22, 1921, pp. 1595–1598 and (discussion) pp. 1598–1600, 11 figs. Describes two satisfactory systems, with comments on their relative characteristics and particular work for which each is most adaptable. (Abstract.) Paper read before Engrs., Soc. West. Pa.

Continuous. Continuous Rolling-Mills, John W. Sheperdson. Engrs. Soc. of Western Pa. Proc., vol. 37, no. 4, May 1921, pp. 221–252 and (discussion) 253–257, 15 figs. Discusses advantages of continuous rolling process, and describes the various types of continuous mills, viz., billet mills, sheet-bar mills, wire-rod mills, mills for rolling flat finished products, merchant mills, etc.

Friction. Friction in Rolling Mills, William F. Parish. Iron Age, vol. 108, no. 26, Dec. 29, 1921, p. 1661. Effects of proper lubrication shown in reduced power losses. (Abstract.) Paper read before Am. Soc. Lubrication Engrs.

Mannesmann Inclined Rolls. Formation of Holes with the Inclined Roll (Mannesmann) Process (Ueber die Lochbildung beim Schrägwalzverfahren), J. Gassen. Stahl u. Eisen, vol. 41, no. 49, Dec. 8, 1921, pp. 1767–1771, 13 figs. Writer's experiences with formation of cracks with hollow ingot rolling. It is shown that most favorable but also most difficult position for axis of rolling material is exactly in center of both rolls at point of crossing.

Production and Yield. Production and Yield of Rolling Mills, Joseph F. Shadgen. Iron Age, vol. 109, nos. 1 and 2, Jan. 5 and 12, 1922, pp. 43–46 and 151–152, 1 fig. Jan. 5: Their present state of development. Useful operating data. Losses which should be lessened. European practice leads in yield. Jan. 12: Dependence of material yield on oxidation and on bloom and billet cropping. Temperature limitations are said to govern reheating.

Semi-Continuous Bar. Semi-Continuous Bar Mill for Alloy Steel, F. L. Prentiss. Iron Age, vol. 109, no. 2, Jan. 12, 1922, pp. 141–144, 5 figs. Cooling equipment embodies inclined escapement and horizontal notched bed features. Flat spring steel is self-annealed in packs.

Tandem Rolling. Tandem Rolling of Cold-Rolled Steel. Iron Age, vol. 109, no. 3, Jan. 19, 1922, pp. 211–213, 7 figs. Special equipment developed for this purpose, including rolls and their housings, wire straighteners, edge rolls, Turk's head and cross slides.

RUBBER

Stress-Elongation Curve. The Stress-Elongation Curve of Vulcanized India-Rubber, Emil Hatschek. Jl. Soc. Chem. Industry, vol. 40, no. 21, Nov. 15, 1921, pp. 251T–253T, 3 figs. Compares curves for samples of a definite rubber-sulphur mixture cured for definite lengths of time, and deduces formulas.

Testing. The Testing of Rubber Goods. U. S. Bur. of Standards Circular, no. 38, Sept. 28, 1921, 127 pp., 47 figs. Gives methods used at Bureau in testing of rubber goods. Describes various physical tests commonly applied and machines used for this purpose, many of which were designed in Bureau.

ZELCO
RING
100% 1 PIECE PISTON RING
Coated

The goal of every automotive engineer—of every first class mechanic—has been a quick seating piston ring.

In the ZELCO we have it—we have scientifically applied a well-known mechanical principle (patents pending) and ZELCOS mark a new era in piston ring development.

ZELCOS are made of a special grade of tough, white cast iron, peened by a special process so that the ring when installed is a *perfect circle*, thus insuring an absolute fit on the cylinder walls.

The ring is coated on its face with 2/1000ths of an inch of zinc, deposited by a special method by which a uniform surface of this soft metal is obtained. The entire ring is then coated with 1/30th of 1/1000th of zinc. In use this surface wears to a perfect fit in from 30 minutes to an hour, simultaneously filling up any small scores or porosities in the cylinder wells.

ZELCOS do not shopwear—they do not rust.

ZELCO IS THE FINAL ANSWER TO THE
ONE PIECE PISTON RING PROBLEM

Walter A. Zelnicker Supply Co.

1600 Kingsland Ave.
Wellston District
St. Louis, Mo.

Data are given showing effect of various factors on tensile properties of rubber. Effect of temperature on physical tests. Brief outline of methods of collecting crude rubber and processes used in manufacture of various rubber articles.

S

SCIENTIFIC MANAGEMENT

See INDUSTRIAL MANAGEMENT.

SCREWS

Efficiency. Efficiency of Screws, C. D. Albert. Sibley Jl. of Eng., vol. 36, no. 1, Jan. 1922, pp. 2–3, 1 fig. Comparison of correct and approximate expressions.

SEMI-DIESEL ENGINES

Hydroelectric Plant. A Combined Hydro and Semi-Diesel Plant at Minnedosa, Manitoba. Power, vol. 55, no. 3, Jan. 17, 1922, pp. 92–93, 2 figs. Semi-Diesel engines installed in hydroelectric plant to carry load during periods of low water.

SEWAGE DISPOSAL

The Economy of the OMS Sewage Purification Process. (Wirtschaftlichkeit und Frischwasserklärung bei dem OMS-Verfahren in Gegensatz zu uebengelagerten Schlammfaulräumen), H. Schnickel and O. Mohr. Gesundheits-Ingenieur, vol. 44, no. 43, Oct. 22, 1921, pp. 545–547. Schinckel disputes the practicability of the OMS process, because the fresh-water settling tank is in constant connection with the putrefying chamber. In his reply, Mohr points out that neither is purely fresh sludge recovered from the Kremer purification process, according to which the putrefying chamber is located parallel to settling tank.

SHAFTS

Oscillations. Calculation of Torsional Oscillations of Shafts (Zur Berechnung der Verdrehungsschwingungen von Wellenleitungen), J. Geiger. Zeit. des Vereines deutscher Ingenieure, vol. 65, no. 48, Nov. 26, 1921, pp. 1241–1242, 6 figs. Describes new and very simple method of determining coefficient of torsional oscillation and the true angle of deviation; and method of calculating reduced length of crank.

SHEET-METAL WORK

Elbows. New Machine Making Two Elbows a Minute. Sheet Metal Worker, vol. 12, no. 25, Jan. 6, 1922, pp. 854 and 855, 2 figs. Describes Lyon-Conklin elbow machine which turns blank sheets into elbows.

SHIPS, CONCRETE

Resistance. The Resistance of Reinforced-Concrete Ships (Das Eisenbetonschiff und sein Widerstand), L. Kostanjevic. Beton u. Eisen, vol. 20, no. 17–18, Nov. 4, 1921, pp. 199–200. Writer presents a few practical examples supplementary to article by F. Gebers in previous issue of same journal.

SILICA BRICK

Manufacture. The Manufacture of Silica Brick, A. W. McMaster. Iron & Steel of Can., vol. 4, no. 10, Nov. 1921, pp. 267–268. Describes inauguration of the manufacture at Cape Breton from local materials. Operating costs; comparative analyses of quartzites; burning.

SLIDE RULES

Decimal Point Determination. Decimal Point Determination in Slide Rule Operation, James Theron Rood. Wisconsin Engr., vol. 26, no. 2, Nov. 1921, pp. 19–22, 3 figs. Gives examples to show how to secure greater accuracy.

SLOTTING MACHINES

Horizontal. Investigation of a Horizontal Slotting Machine with Electric Separate Drive and Belt Coupling Devices (Untersuchung einer Wagerechtstoszmaschine mit elektrischem Einzelantrieb und Riemenzwischengliedern), G. Schlesinger. Werkstattstechnik, vol. 15, no. 22, Nov. 15, 1921, pp. 645–647, 7 figs. Abstract of comprehensive work giving results of many years of research and experimental work carried out by author in coöperation with Dr Kurrein. Results are shown in diagrams on performance of machine and on manner of power distribution during forward and return stroke.

SMOKE PREVENTION

Devices. The Black Smoke Problem, David Brownlie. Iron & Coal Trades Rev., vol. 103, no. 2807, Dec. 16, 1921, pp. 872–873. Causes and preventive devices; low-temperature carbonization.

SPRINGS

Railway-Car. The Springs of Railway Cars (Om Jernbanevognes Fjedre), Rich. Holm. Ingeniören, vol. 30, no. 67, Aug. 20, 1921, pp. 497–501, 14 figs. Form of plate ends is claimed to be of great influence. Shape of ends should be parabolic and the trapeze shape is inexpedient. A spring with parabolic ends can absorb double the work of one with ends cut off at right angles.

STANDARDIZATION

Place of Laboratory in. The Place of the Laboratory in Standardization, W. P. Dobson. Eng. Inst. Can. Jl., vol. 5, no. 1, Jan. 1922, pp. 11–15, 6 figs. Types of engineering standards; measurement, constants, quality, performance; practice; work of laboratory in determining standards, methods employed by laboratories of Hydroelectric Power Commission of Ontario.

STANDARDS

German N.D.I. Report. Report of the German Industry Committee on Standards (Mitteilungen des Normenausschusses der Deutschen Industrie). Betrieb, vol. 3, no. 25, Sept. 15, 1921, pp. 367–379, 18 figs. Accepted standards for blank cylinder, round-head, and countersunk-head screws. Proposals of Board of Directors for drawings for recording dimensions; straight wooden stairs for small dwellings; window and door hinges. Proposed standards for screw joints.

Report of the German Industry Committee on Standards (Mitteilungen des Normenausschusses der Deutschen Industrie). Betrieb, vol. 3, no. 26, Sept. 25, 1921, pp. 393–406, 21 figs. and supp. table. Proposals of Board of Directors for ball bearings. Proposed new standards for round-head rivets for boiler and structural steel work; countersunk-head rivets and countersunk oval heads.

STEAM

Generation and Utilization. Fuel Economy by the Adoption of Scientific Management in Steam Generation and Utilisation, David Brownlie. Eng. & Indus. Management, vol. 6, nos. 23, 24 and 25, Dec. 8, 15 and 22, 1921, pp. 653–656, 7 figs.; 685–687, 4 figs.; and 719–722, 5 figs. Dec. 8: Feedwater heaters. Dec. 15 and 22: Superheaters, and boiler and pipe covering.

STEAM-ELECTRIC PLANTS

Equipment. Rauber's Report to the Commission for Utilization of Fuels (Rapport de M. Rauber a la Commission d'utilisation des combustibles). Chaleur et Industrie, vol. 2, no. 19, Nov. 1921, pp. 727–735. Discusses steam-electric central stations, their equipment, type of boilers, superheat, economizers, feedwater heaters, etc.

STEAM ENGINES

Unaflow. Unaflow-Engine Guarantees and Tests, L. A. Quayle. Power, vol. 55, no. 3, Jan. 17, 1922, pp. 98–99, 1 fig. Universal unaflow engine exceeds guarantees on acceptance tests made after four years of continuous operation.

STEAM METERS

Kent Marine. The Metering of Steam for Marine Purposes, also of Oil and Air, C. R. Sams. Trans. Inst. Mar. Engrs., vol. 33, Oct. 1921, pp. 375–388 and (discussion) 388–393, 10 figs. Describes the Kent steam meter which consists of an orifice carrier, cooling chambers and pressure piping, and a diagram recorder.

STEAM TURBINES

Design and Operation. Major Turbine Troubles Diminished. Elec. World, vol. 79, no. 2, Jan. 14, 1922, pp. 77–80, 2 figs. Discusses blading, lubrication, and vibration; growth in turbine ratings; improvements in design.

STEEL

Chrome. See CHROME STEEL.

Crucible. Comparison of American and English Methods of Producing High Grade Crucible Steel, T. Holland Nelson. Raw Material, vol. 4, no. 12, Dec. 1921, pp. 424–433, 24 figs. Discusses the merits and shortcomings of American and English practice. Presented before Am. Soc. for Steel Treating.

Deoxidation and Desulphurization. Deoxidation and Desulphurization in the Heroult Furnace, F. T. Sisco. Chem. & Met. Eng., vol. 26, no. 1, Jan. 4, 1922, pp. 17–22. Describes three methods of working up a heat of steel. Discusses composition and characteristics of slags. Believes that good steel from poor scrap is a question of knowledge and skill.

Electric vs. Crucible. Crucible and Electric Tool Steel, W. J. and S. Stuart Green. Iron Age, vol. 109, no. 3, Jan. 19, 1922, pp. 201–205. Some aspects and choice in their manufacture. Points out that electric furnace bids fair to supplant crucible to greater degree than heretofore, though it is possible never completely.

Etched, Strain Figures in. Strain Figures in Etched Steel, A. Fry. Engineering, vol. 112, no. 2920, Dec. 16, 1921, pp. 809–811, 11 figs. Examples of peculiar strain figures observed by author on specimens of mild steel etched according to a modified new method. Author points to parallel between his observations and what is known as "blue brittleness."

Hardening by Overstrain. The Hardening of Steel by Overstrain, R. W. Chapman. Commonwealth Engr., vol. 9, no. 3, Oct. 1, 1921, pp. 74–75, 2 figs. Describes test showing that when steel is overstrained in tension so that its elastic limit in tension is raised, its elastic limit in compression is correspondingly lowered, and vice versa.

Manganese. See MANGANESE STEEL.

Melting. Leaves from a Steel Melter's Notebook, Henry D. Hibbard. Iron Age, vol. 108, nos 17 and 21, Oct. 27 and Nov. 24, 1921, pp. 1065–1067 and 1337 and 1379–1380. Oct. 27: Experience in making hollow ingots for seamless pipe; effervescing and "killed" steel in an acid furnace. Nov. 24: Design of structure to resist shock or overstrain; car-coupler test illustrating necessity of proper distribution of metal.

Molybdenum. See MOLYBDENUM STEEL.

Ordnance. Effect of Sulfur and Oxides in Ordnance Steel, William J. Priestley. Trans. Am. Inst. Min. & Metallurgical Engrs., no. 1109-S, 1921, 15 pp., 3 figs. Describes method by which desired physical properties of steel may be procured—by elimination of certain impurities that inherently exist in steel made by open-hearth process, and without use of expensive alloys. Abstract of paper in Min. & Metallurgy, no. 180, Dec. 1921, pp. 34–35. See also Iron Age, vol. 108, no. 26, Dec. 29, 1921, pp 1658–1661, 3 figs.

Tungaten, Metallography. A Metallographic Study of Tungsten Steel (En metallografisk studie av volframstål), Axel Hultgren. Jerkontorets Annaler, vol. 105, no. 12, 1921, pp. 499–525, 22 figs. Discusses investigations as to transformations, critical points, free carbide, equilibrium diagrams and their signifiance, etc. Bibliography.

STEEL CASTINGS

Railway Rolling Stock. Large Steel Castings for Railway Rolling-Stock, Ry. Engr., vol. 42, no. 503, Dec. 1921, p. 445, 3 figs. Describes production in the form of single castings, of locomotive tender underframes, platform and end members for passenger rolling-stock and trailer trucks for locomotives by Commonwealth Steel Co., St. Louis.

STEEL, HEAT TREATMENT OF

Characteristic Curves. Characteristic Curves for Heat Treatment of Steels (Les "Courbes caracteristiques" des traitments thermiques des aciers), Albert Portevin and Pierre Chevenard. Révue de Metallurgie, vol. 18, no. 11, Nov. 1921, pp. 717–726 and (discussion) 727–728, 11 figs. Discusses the interdependence of temperature of heating and rapidity of cooling, the final state being a function of these two variables. Paper read before Iron & Steel Inst., Paris.

Elements. Elements of the Heat-Treatment of Steel, H. J. French. Am. Mach., vol. 55, nos. 23, and 24, Dec. 8 and 15, 1921, pp. 907–908 and 960–964, 15 figs. Dec. 8: Operations in heat treatment; changes in structure while heating; changes produced by tempering and hardening; seasoning; effect of carburization. Dec. 15: Quenching operations; tempering.

Tool Steel. Volume Changes in Tool Steel on Heat Treating, L. A. Lanning. Forging & Heat Treating, vol. 7, no. 12, Dec. 1921, pp. 610–611, 2 figs. Effect of rates of heating, temperatures and quenching medium upon dimensions of cylindrical pieces of tool steels. Critical rate of heating important in hardening.

STEEL, HIGH-SPEED

Hardness. Hardness of High-Speed Steel, A. H. d'Arcambal. Chem. & Met. Eng., vol. 25, no. 26, Dec. 28, 1921, pp. 1168–1173, 8 figs. Hardness at various temperatures, hardness in the cold after various heat treatments, and cutting efficiency determined in an effort to predetermine usefulness of a modern machine tool.

Various Methods for Hardening High-Speed Steel, A. H. d'Arcambal. Chem. & Met. Eng., vol. 25, no. 25, Dec. 21, 1921, pp. 1150–1151. Discusses salt bath hardening, pack hardening, lead bath hardening, and semi-muffle furnace hardening.

Metallography. The Metallography of High Speed Steel, J. P. Gill and L. D. Bowman. Am. Soc. for Steel Treating Trans., vol. 2, no. 3, Dec. 1921, pp. 184–205, 56 figs. Discusses critical points and constitution of high-speed steels; secondary hardness; etching reagents; nomenclature; etc.

STEEL MANUFACTURE

Basset Process. The Basset Process (Le Procédé "Basset"). L'Outillage, vols. 235 and 236, nos 47 and 48, Nov. 24 and Dec. 1, 1921, pp. 1259–1260 and 1287–1288, 1 fig. Gives copy of Basset's French patent published April 2, 1920, "Rotary furnace system for direct production of iron or steel or of pig iron," and discusses it and its prospects.

STEEL WORKS

Cold-Drawing Plant. LaSalle Co. Completes Cold Drawing Plant, Gilbert L. Lacher. Iron Age, vol. 109, no. 1, Jan. 5, 1922, pp. 27–31, 6 figs. Designed for handling products in maximum lengths. Raw materials protected from elements.

Furnaces and Gas Producers. Steel Works Furnaces and Gas Producers, J. S. Atkinson. Jl. West of Scotland Iron & Steel Inst., vol. 29, Part 1, Oct., Session 1921–1922, pp. 4–11 and (discussion) 11–14, 10 figs. on supp. plates. Discusses the principle of gas firing, mechanical producers, regeneration or recuperation, open-hearth furnaces, soaking pits, etc.

Krupp. Recent Developments in the Krupp Works at Essen. Engineer, vol. 132, no. 3441, Dec. 9, 1921, pp. 611–613, 8 figs. partly on p. 632. Account of its development and details as to its work during war, and peace-time activities.

Power Generation. Power Generation in Steel Plants, D. M. Petty. Engrs. Club of Philadelphia Jl., vol. 38-12, no. 204, Dec. 1921, pp. 302–397, 2 figs. Conclusions drawn from actual operating conditions of steel plant: Cost of power can be effectively reduced by increasing load factor; load factor in steel mills may be increased by careful arrangement of load and by supplying to central stations all surplus power not required during light load periods; etc.

STOKERS

Mechanical vs. Hand. Hand *versus* Mechanical Handling of Coal and Ashes in Municipal Power Plants—II, W. F. Schaphorst. Am. City, vol. 25, no. 5, Nov. 1921, pp. 415–421, 2 figs. Notes on underfeed and hand stokers, and points to be considered in selection of ash-handling system.

Wood-Refuse-Burning. Burning Wood Refuse in Mechanical Stokers, R. L. Beers. Power House, vol. 15, no. 1, Jan. 5, 1922, pp. 30–33, 8 figs. Describes various types of boilers fitted with underfeed stokers for wood and other factory refuse.

Cadman BEARITE

Mechanically Correct

Cadman Bearing Metals can be guaranteed to double the life of the great majority of bearings largely because they are mechanically correct.

A jealously guarded reputation for 60 years of consistent bearing service to the principal industries of America rests upon the fulfillment of this guarantee.

The microphotograph to the left above is that of a high-grade lead-base babbitt. Antimony, the essential hardening material, instead of being uniformly distributed, is partly scattered through the comparatively soft base in the form of hard brittle crystals.

The microphotograph to the right is Cadman BEARITE. The analysis of the two metals is identical, but the hardening in the Bearite is uniformly distributed through the metal and the objectionable crystals are eliminated.

We ask you, as an engineer, which metal is structurally correct and which will give the better service?

MECHANICAL ENGINEERING

Volume 44 April, 1922 Number 4

The Strength of Mechanically Welded Pressure Containers

By R. J. ROARK,[1] MADISON, WIS.

This paper describes pressure tests made on electrically welded, gas-welded, and riveted pressure containers, and tension and shear tests made on specimens cut from such containers and on specially prepared specimens of welded metal. The tests were made for the Vilter Manufacturing Company of Milwaukee, Wis., and had for their purpose the demonstrating of the strength and uniformity of construction in which the electric weld is employed

The results of the tests indicate that in containers of the type studied, electrically welded head joints are sufficiently strong to develop the full strength of the shell and heads; that it is practicable to make electrically welded joints which are uniform in respect to tensile strength, shearing strength and structure of fused metal; that for the particular combination of metals tested, the tensile strength of such welded joints is about 28,500 lb. per sq. in. and the shearing strength about 25,500 lb. per sq. in.; that for the combination tested, the metal in the weld is less strong and less ductile than either the base metal or the filling metal before fusion; that the electrically welded joints tested were stronger in shear but weaker in eccentric tension than the riveted joints tested.

THE investigation which forms the subject of this paper was made by the writer for the Vilter Manufacturing Company of Milwaukee, who furnished all test specimens. The tests on the containers were carried out at the works of the company. The tests on the specimens cut from the containers and on the specially prepared specimens were made in the Materials Testing Laboratory of the University of Wisconsin.

The writer wishes to acknowledge the helpful coöperation of the officers of the Vilter Manufacturing Company, their readiness to submit their product to any test suggested and their promptness in furnishing the necessary specimens and appliances. Thanks are due for helpful suggestions to Prof. G. L. Larson, Professor of Steam and Gas Engineering at the University of Wisconsin, who witnessed the test on containers.

PURPOSE AND SCOPE OF THE INVESTIGATION

The primary purpose of this investigation was to demonstrate the strength and uniformity of a certain type of commercial pressure container with electrically welded head joints. These containers were made of lap-welded pipe and were provided with spherical flanged heads. Their dimensions are given in Fig. 1. The average physical and chemical properties of the steel used, as reported by the company furnishing it, were as follows: Yield point, 38,000; ultimate, 64,000; elongation, 27 per cent; carbon, 0.17 per cent; manganese, 0.44 per cent; phosphorus, 0.010 per cent; sulphur, 0.027 per cent. It was proposed to determine the absolute strength of such containers by pressure tests on representative samples and to establish a comparison with vessels of like form and dimensions, but with gas-welded and riveted heads, by similar tests on such containers. In order to secure a more positive check on the uniformity of the joints and more specific information as to their strength under various conditions of stress, it was planned to cut from the containers specimens of such form as to give, when subjected to laboratory tests, the desired information. Partly to determine the best form for such specimens and the best method of testing them, and partly to aid in the interpretation of results, strain measurements were made on certain of the specimens during the tests. From these measurements relations were established between the internal pressure in a vessel of the standard type and the resulting stresses on the head joint.

In order to gain still more detailed information concerning the physical properties of welded joints, various special specimens of welded metal were made up and tested as subsequently described.

It is thus seen that the investigation comprised three more or less distinct series of tests, namely, tests on containers, tests on specimens cut from containers and tests on special specimens of welded metal.

TESTS ON CONTAINERS

In all, nine containers were tested. In each case, the tests consisted of subjecting the specimen to an internal hydraulic pressure which was gradually increased until rupture resulted or such rapid leakage developed as to make further increase of pressure impracticable. Pressure was in most cases applied in predetermined increments by a hand pump, and was measured by an indicating gage which had been calibrated immediately before its use in these tests.

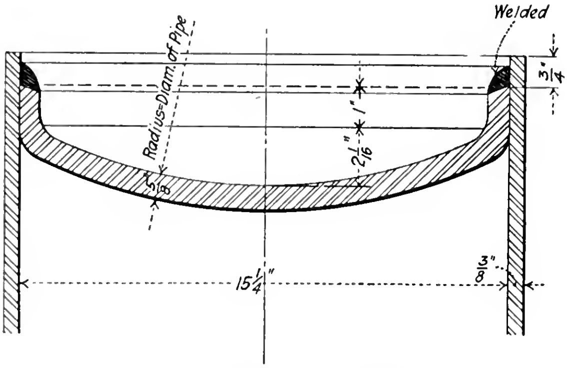

FIG. 1 SHAPE AND DIMENSIONS OF SPECIMEN CONTAINERS

Some of the specimens were of standard design. Some were so made as to secure failure of a particular sort, in order to provide information on some specific point. In order to compare the work of different operators, two similar gas-welded specimens were made up, the welds being made by different operators. On certain of the containers of standard design, strain measurements were made as mentioned above.

A few of the tests described separately below and a summary of the complete results obtained, is presented in Table 1. Accompanying photographs show the appearance of some specimens after testing, and indicate the manner of failure.

Specimen No. 1 was subjected to successive pressures of 200, 400, 800, 1200, 1600 and 1750 lb. per sq. in. Strain measurements were taken at each pressure which was then reduced to zero. The maximum pressure was then applied. At a pressure of 1750 lb. per sq. in. the coupling started to leak. The tank had visibly increased in diameter and the elastic limit had evidently been

exceeded. At a pressure of 1925 lb. per sq. in. leakage occurred at the weld of the nipple. A new nipple was welded on and the pressure increased to 2150 lb. per sq. in., when the specimen ruptured. Failure was due to circumferential tension in the shell. The heads did not reverse. (Fig. 2.)

Successive pressures of 500, 1000, 1500 and 1800 lb. per sq. in. were applied to specimen No. 2. Strain measurements were made at each pressure up to and including 1500 lb. The pressure was not reduced to zero after each application but was maintained and increased to the maximum without release. No leakage developed, but at a pressure of 2150 lb. per sq. in. one head reversed. At a pressure of 2200 lb. per sq. in. the specimen ruptured and the reversed head was violently forced off. Failure was due to combined longitudinal tension and bending, a crack in the outside face of the welded metal, indicating a local failure due to bending. (Fig. 3.)

Fig. 2 Specimen No. 1 (Electrically Welded), Showing Fracture After Testing

In testing specimen No. 3, successive pressures of 200, 400, 800, 1200, 1600, and 1800 lb. per sq. in. were applied. Strain measurements were made at each pressure before being reduced to zero. The maximum pressure was applied by power on the second day of the test. At a pressure between 1200 and 1600 lb. per sq. in. leakage was observed at both ends next the rivets and in the weld at the nipple. The nipple was replaced and the test continued. When 1800 lb. per sq. in. was reached the leakage became so bad that it was impossible to increase the pressure further by hand. By means of a power pump a pressure of 2100 lb. per sq. in. was attained but leakage prevented further increase. The container did not rupture nor did the heads reverse.

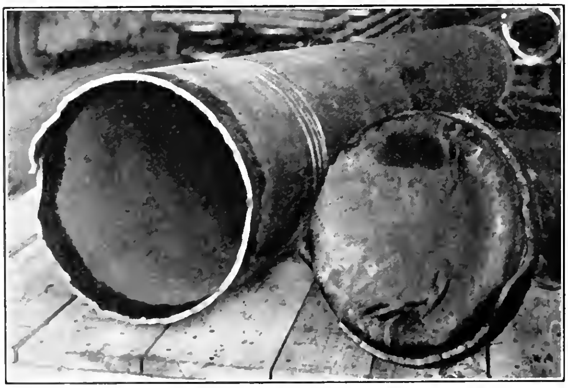

Fig. 3 Specimen No. 2 (Gas Welded) Showing Fracture and Inner Side of Reversed Head

The testing of specimens Nos. 4 and 5 offers an opportunity to compare the work of different gas-welding operators as the two containers were similar in design and dimensions but welded in different shops.

Stress on Head Joints

During the tests on specimens Nos. 1 and 2, strain measurements were made at sections distant 1 in., 2 in., 3 in., and 5 in. from the end. The measurement at the end was made on a diameter by means of a wire-wound dial reading to one ten-thousandth of an inch. The other measurements were made in one case by means of a Berry strain gage, on a 2 in. gage line, and in the other case by means of wires which encircled the container and which were provided at both ends with lugs, between which measurements could be made to one-thousandth of an inch by means of an ordinary micrometer. Owing to the danger of explosive failure, readings were taken only up to about three-fourths the computed bursting pressure.

From the measurement thus made the stress at each section was computed, employing as the value of the modulus of elasticity, 29,000,000 lb. per sq. in. The stress at each section was then expressed as a percentage of the stress which would exist in a similar cylinder having the same internal pressure and not subject to end restraints. By plotting for each section a diagram of stress against pressure up to the maximum pressure at which readings were taken, the probable stress at bursting pressure (taken for this purpose as 2000 lb. per sq. in.) was determined by extrapolation. A diagram was then plotted in which these stresses (expressed as percentages of the normal stress) were used as ordinates and distances from the end of the specimen to where these stresses occurred were used as abscissae. The resulting diagram is shown in Fig. 5. In this diagram a portion of the shell is shown with the radial forces which act upon it. The inward forces (shown acting down) consist of the radial components of the circumferential stresses, determined as explained above. The outward forces (shown acting up) consist of the uniform internal pressure, which of course extends only to the beginning of the weld. The portion of the shell shown is in equilibrium under these forces and the stresses acting, and by applying the appropriate conditions of equilibrium the stresses on each of the important sections A-A, B-B, and C-C, were determined. They are represented in Fig. 6, 7 and 8. In the determination of these stresses the bending moment and shear at the section where the circumferential stress becomes equal to the stress which would exist if there were no end restraint, are assumed to be zero. This is not strictly correct, but it is not believed that the assumption introduces a considerable error.

The stress on section C-C depends upon the tension in the band of welded metal (shown in dotted line), and as the section area of this band is non-uniform and difficult to determine, it is probable that the stresses as computed for this section are more in error than the others. All of the results given are, to be regarded as approximations. They represent the nature of the stresses existing and the order of their magnitude, rather than their precise values. A rough check upon the correctness of these computed stresses is afforded by the manner in which the standard gas-welded container (specimen No. 2) failed and the pressure which caused rupture. This specimen failed on section B-B, and the form of fracture showed very clearly that the failure was principally due to flexure. The corrected pressure at rupture was 2090 lb. per sq. in. Using this as the value of P and computing the maxi-

Fig. 4 Specimen No. 7 (Reinforced Electric Weld) Showing Fracture After Testing

mum fiber stress from the tension and moment indicated by Fig. 7 and the known thickness of the plate, a value of 77,000 lb. per sq. in. is obtained, which agrees very well with the modulus of rupture of the metal as determined by other tests. It will be noted that so far as conditions at the ends are concerned, section B-B is the weak point in the standard containers, as would be expected from the thinness of the metal there and the large bending moment, accompanied by direct tension. Section C-C appears to be the next weakest point. Local failure occurred on this section in specimen No. 2 and in the case of the reinforced specimen No. 7, (Fig. 4) about half the fracture was on section B-B and half on C-C. Apparently the surface of contact between the weld and the shell (section A-A) is stronger than either of the other two sections and in no case did failure take place on this section.

The values given for maximum shearing stress and maximum tensile stress in Table 1 were computed for section A-A. It is to be noted that they do not represent the strength of the material in shear and tension, but simply the approximate shear and tensile stress produced in the welded joint by a pressure which caused failure at some other point.

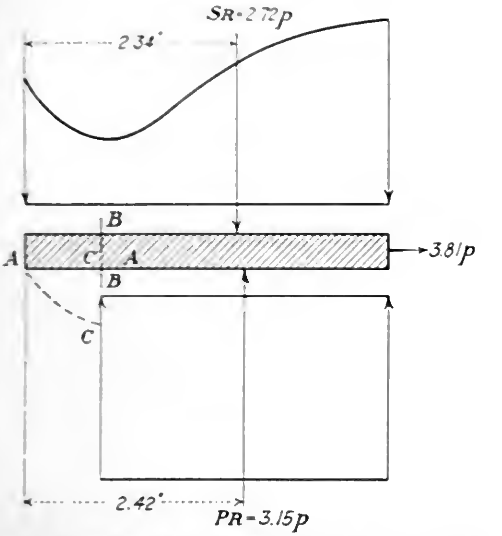

Fig. 5 Stress, Shear and Moment Diagrams of Container

In order to compare the stiffness and elasticity of the welded and riveted types of containers, measurements were made to determine the protrusion and permanent set induced in the heads of certain of the specimens by the pressures applied. These measurements, which were made on containers Nos. 1 and 3, were taken to the nearest one thousandth of an inch by means of Ames dials, readings being taken during the application of each pressure and after its release. The values given for protrusion and set represent respectively the total and the permanent displacement of the center of the head with respect to the end of the cylindrical shell. The data obtained from these measurements were used in plotting the curves of Fig. 9.

Tests on Specimens Cut from Containers

It is apparent from the stresses represented in Figs. 6, 7 and 8 that the important stresses on the head joint are shear and tension, the latter being largely due to flexure. It appeared advisable therefore to cut from the containers specimens of such form as to make it possible to subject portions of the joint included therein to shear and flexure. Two forms of specimens were decided upon. Their form and part of the container from which they were cut are represented in Figs. 10, 11 and 12.

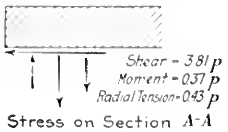

Fig. 6

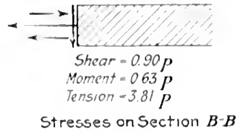

Fig. 7

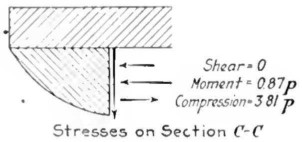

Fig. 8

Figs. 6, 7 and 8 Stress, Shear and Moment Diagrams of Container Sections

Specimens of Type A were tested in tension, the ends being held in wedge grips. The breaking load, eccentricity at rupture and manner of failure were noted. From the data thus obtained, the computed ultimate tensile stresses on the weld was determined. The results of these tests are tabulated in the complete paper while the appearance of the specimens before and after testing are shown in Figs. 13 and 17.

TABLE 1 RESULTS OF PRESSURE TEST ON CONTAINERS

Specimen Number	Description of Specimen	Pressure in Lb. per Sq. in. at			Method of Failure	Stresses on Head Joint at Maximum Pressure					Remarks
		First observed Leakage	Disking of Heads	Maximum		Longitudinal shear lb. per linear inch of joint	Radial tension lb. per linear inch of joint	Bending moment inch-lb. per linear inch of joint	Max. resultant shearing stress lb. per sq. in.	Max. resultant tension stress lb. per sq. in.	
1	Standard commercial container with electrically welded heads, size 16 in. × 10 ft.	1925 (1820)		2150 (2040)	Longitudinal crack, started at nipple	7770	870	1780	9800	15000	
2	Standard type container with gas welded heads, size 16 in. × 10 ft.		2150 (2040)	2200 (2090)	Head forced off	7960	900	1820	10500	16000	Fracture on section B–B
3	Standard type container with riveted heads, size 16 in. × 10 ft.	1200 (1120)		2100 (2000)	Excessive Leakage						
4	Container with gas welded heads and gas welded longitudinal butt joints, size 16 in. × 10 ft. (weld by Le Quelle)			1600 (1540)	Split along long. butt weld						
5	Container with gas welded heads and gas welded longitudinal butt joints, size 16 in. × 10 ft. (weld by Vilter)			1300 (1240)	Split along long. butt weld						
6	Container with electrically welded heads and electrically welded longitudinal butt joints, size 16 in. × 10 ft.			1400 (1340)	Split along long. butt weld						
7	Reinforced container with electrically welded heads (3 concentric shells, concrete filled), size 10 in., 12 in., 14 in. × 3 ft. 2 in.		4500 4800	4800 (4680)	Head forced off	11860			18000		Fracture on sections B–B and C–C
8	Reinforced container with gas welded heads (3 concentric shells, concrete filled), size 10 in., 12 in., 14 in., × 3 ft. 2 in.	4350 (4230)	4100 (3980)	4350 (4230)	Excessive leakage at weld joints	10720					
9	Special container with one electrically welded; one head riveted, size 16 in. × 2 ft.	1750 (1670)		2500 (2390)	Split along lap weld	9100			11600	17600	

Specimens of Type B were tested in shear. The method of testing is shown by the photograph (Fig. 14) of the shear tool with specimen in place. This shear tool was designed to hold the specimen in such a position that the line of action of the applied load passed through the neutral axis of the section being tested. This necessitated inclining the plane of the section slightly and so introduced a small compression, but it eliminated the bending moment which would otherwise have existed. In general, the specimen failed to shear, as was intended, but in some cases it was found impossible to secure a shear failure, the adjacent metal crushing, tearing or bending before the weld gave way. A tabulation of the results secured from these tests is presented in the complete paper. The appearance of the specimens tested is shown in Fig. 15.

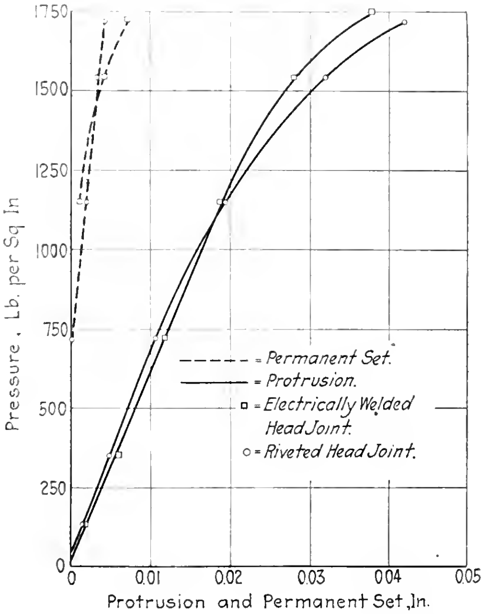

Fig. 9 Protrusion and Permanent Set of Container Heads at Different Pressures

Tests on Specially Prepared Specimens of Welded Metal

Two types of special specimens were tested. One was made by welding together a number of narrow strips of $^3/_8$-in. plate edge to edge and then cutting from the composite plate so formed a number of strips perpendicular to the welded joints. As eight strips were welded together each specimen had seven transverse welds in it. These specimens were tested in tension and the ultimate strength and per cent elongation noted. Eight specimens were thus made and tested, four having gas-welded joints and four having electrically welded joints. The results are presented in a table in the complete paper and the appearance of the specimens is shown by Fig. 16.

The other type of special specimen was made by welding together two $^3/_8$-in. plates edge to edge and cutting two pieces from the composite plate so formed, one along the center line of the weld and one from one of the plates, parallel to, but some distance away from the weld. Two sets of such specimens were prepared from plates electrically welded together and two sets from plates gas-welded together. One set of each kind was tested in tension, an extensometer being used and the proportional elastic limit, yield point, ultimate strength, modulus of elasticity, per cent elongation and per cent reduction of area determined. The results are tabulated in the complete paper while the stress strain diagrams are shown in Fig. 18.

TABLE 3 CHEMICAL CONSTITUTION OF SPECIAL SPECIMENS AND OF WELDING BARS

(Analyses by Robert W. Hunt Co.)

Specimen	Per cent Carbon	Per cent Manganese
Piece from center of electric weld	0.18	0.05
Piece from center of gas weld	0.06	0.08
Piece from plate remote from weld	0.12	0.51
Welding bar No. 1	0.07	0.12
Welding bar No. 2	0.07	0.05

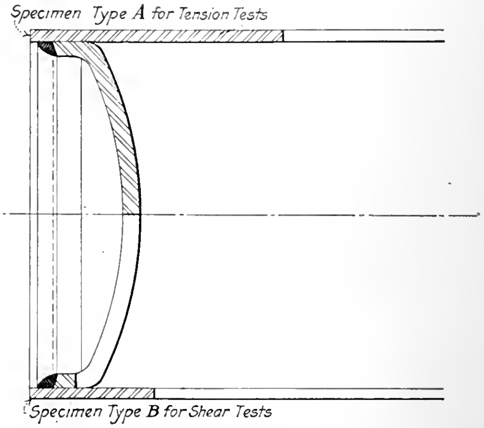

Fig. 10 Form of Specimens Subjected to Shear and Flexure

The remaining specimens were tested in shear. Two welding rods, similar to those used in making up the various containers and other welded specimens, were also tested in shear. The test consisted in subjecting the specimen to double shear while it was rigidly held in a special shear tool that prevented bending. The results of these tests are presented in Table 2.

Chemical analyses were made of each of the specimens of this type and of the two welding rods. The results are presented in Table 3.

Conclusions

Some of the more important points brought out by the tests are enumerated and severally discussed below.

1 *Weak points in the containers.* None of the welded containers of standard design failed primarily at the welded head joint. The nature of the fracture shows that the weak points in the containers were, first, the lap weld in the pipe forming the shell, where failure occurred due to circumferential tension, and, second, the body of the shell at its junction with the head flange, where failure occurred due to the combination of longitudinal tension and bending. It appears that leakage is likely to occur first where couplings and nipples are welded in. This is due to the fact that the metal of the shell stretches and pulls away from the nipple, which does not have a corresponding strain induced in it by internal pressure.

Fig. 14 Shear Tool Used in Testing Type B Specimens

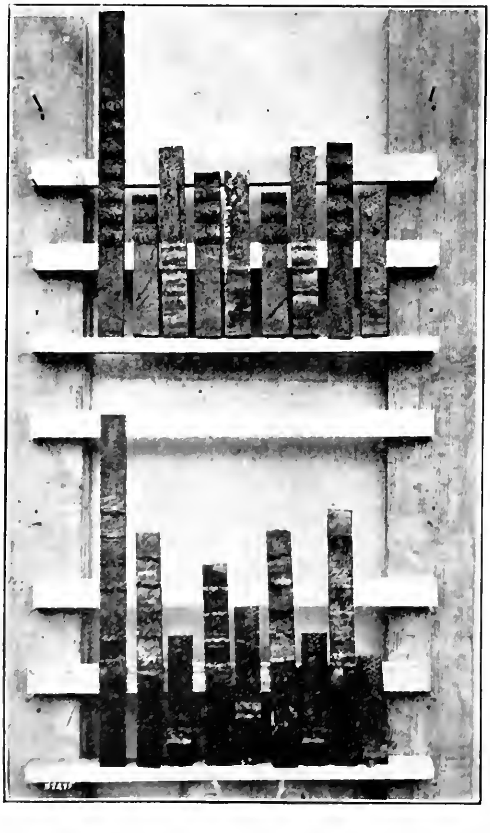

Fig. 16 Special Specimens Cut Transversely to Welded Joints, Tested in Tension

2 *Strength of electric welds.* From the tests on four specially prepared specimens, the average tensile strength of electrically welded joints was found to be 28,500 lb. per sq. in. From tests on five specimens cut from containers, the average shearing strength of electrically welded joints was found to be 25,500 lb. per sq. in. The mean variation from the average tensile strength per linear inch of weld was found to be 2 per cent, and the maximum variation 4.5 per cent. The mean variation from the average shearing strength per linear inch of joint was found to be 5.2 per cent and the maximum variation 7 8 per cent. The results of eccentric tension tests on specimens cut from containers showed that no one of the specimens was markedly weaker than the average for the lot. It is believed that the uniformity of strength thus indicated is of especial interest and importance.

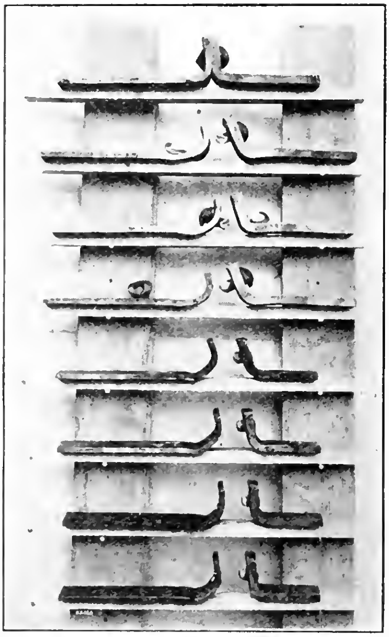

Fig. 17 Specimens of Type A, Riveted

In connection with the values given above for tensile strength, two points should be noted. First, at the section through the weld, where failure took place, the load was eccentric, because of the fact that the specimen is asymmetrically thickened at that point by the joint. This eccentricity undoubtedly made the average stress on the joint at failure less than it would otherwise have been, and so the values obtained were less than the actual tensile strength of the metal. The effective eccentricity was not as great as one half of the excess thickness of the joint, because the ends of the specimen were restrained. No attempt has been made to allow for the effect of this eccentric loading, because it represents a condition inherent in any so-called single-V weld which has an excess thickness.

Second, each of the four specimens had, within its tested length, several transverse welded joints. The strength of each specimen, therefore, represents the strength of the weakest of these seven joints, and so the value given, 28,500 lb. per sq. in., is less than the average strength for all the joints.

3 *Relative strength of electrically welded and riveted joints.* The tension tests on specimens of Type A indicated that the resistance to tension applied with a large eccentricity is greater for the riveted joint than for the welded joint. The shear test on specimens of Type B indicated that the resistance to shear per linear inch of joint is greater for the welded joint. Measurements to determine the elastic and permanent protrusion of the container heads showed that for the two specimens so tested the welded container withstood a somewhat greater pressure without permanent distortion. In the case of the riveted containers, leakage occurred at the head joints under moderate pressures. In the case of the electrically welded containers there was no leakage at the head joint under any pressure.

4 *Efficiency of electrically welded joints.* While it is customary to speak of the efficiency of a joint, whether welded or riveted, meaning the ratio of the strength of joint to strength of plates joined, the writer does not believe that this ratio is especially significant in the case of electrically welded joints nor that any value can be given it that can be regarded as generally applicable.

It is apparent that while the strength of the plates joined is dependent solely on the physical properties of the base metal, the strength of the weld is in great measure dependent on the properties of the filling metal. Furthermore, the per cent excess thickness of the weld, which influences its strength, varies with the thickness of the plates. Accordingly the efficiency of a weld depends on the properties of the base metal, the properties of the filling metal, and the thickness of the plates.

The writer believes that the correct method of computing the efficiency of an electrically welded joint is on the basis of a specified minimum strength of base metal, a specified minimum excess thickness of weld and an experimentally determined average strength (per sq. in.) of the metal, of which the finished weld is composed.

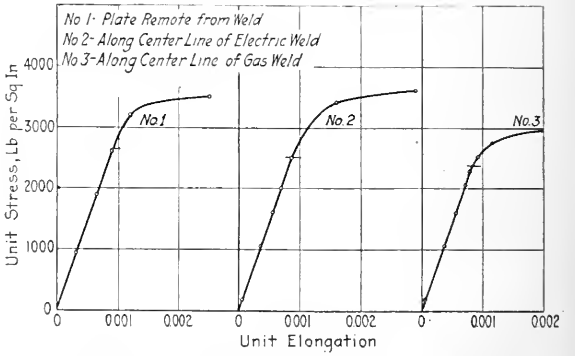

Fig. 18 Stress-Strain Diagram for Special Specimens Cut Parallel to Weld Joints

Liege Engineer Graduates to Hold International Congress

The Association of Graduate Engineers of the Liege School has scheduled an International Scientific Congress for June 11 to 16, on the occasion of the seventy-fifth anniversary of the Liege School. Graduate engineers of recognized schools and scientists of Belgium and the Allied Nations are invited to attend.

The Congress will include seven sections; mining, metallurgy, mechanical engineering, electricity, chemical industries, civil engineering and geology. A list of questions drafted to give an idea of some of the questions to be discussed has been published by the committee, and for the mechanical engineering section they cover turbines, reciprocating engines, jet apparatus, machine tools, transportation equipment, hoisting and handling machinery, special metallurgical apparatus, special mining machinery, applied hydraulics and thermo-dynamics, and combustion. Copies of these questions may be obtained by engineers expecting to be in Liege at that time, by application to the Editor of Mechanical Engineering.

The tentative program includes the unveiling of a War Memorial and the formal opening, a reception and banquet on Sunday, June 11, a reception by the University of Liege Monday morning, opening of the Assembly and meeting of Sections in the afternoon, a reception at the City Hall by the municipal authorities and a concert and ball at the Royal Conservatory of Music in the evening. Beside the meetings a reception at the Governor's Pallace is scheduled on Tuesday, formal closing of the Assembly on Wednesday and visits to the Exposition, to industrial works and points of interest until the closing of the Exposition on Saturday. Further information may be had by addressing O. Lepersonne, Secretaire-General de L'a. I. Lg., 16 Quai des Etats-Unis, Liege, Belgium.

Cotton-Ginning Machinery

BY SOLOMON E. GILLESPIE,[1] DALLAS, TEXAS

Of the two classes of cotton grown in the United States—sea island or long-staple, and upland or green-seed—the former does not adhere to the seed and the lint can be pulled off clean by running it through rollers set close together, leaving the seed behind. Upland cotton, on the other hand, adheres to the seed, and the present paper is devoted to a description of the apparatus developed since Eli Whitney's epoch-making invention in 1792 for mechanically handling the raw seed cotton, removing the lint therefrom, and forming it into shape suitable for delivery to the baling press.

The cotton-ginning process comprises (a) elevating the cotton from the wagons in which it is brought to the ginnery to (b) a cleaner where the dirt, sand, leaf trash and other foreign substances are extracted; (c) elevating the cleaned cotton to (d) feeders which deliver it uniformly to (e) the gins where the lint is removed from the seed by the teeth of circular saws mounted at close intervals on a rotating shaft, from which teeth it is (f) cleaned off pneumatically and (g) carried to a condenser, where it is formed into a "bat" and delivered to a press box for packing, wrapping and pressing. The latest developments of the various devices employed in these steps are described and illustrated in the paper, and the author has included much valuable information for designers in the way of dimensions, relative proportions, speeds of operation, etc.

LONG before the dawn of history the cotton plant was cultivated in various parts of the world, and the earliest records of spinning its fleecy bolls are of such antiquity that it is difficult to obtain satisfactory evidence of its beginning. The name "cotton" itself is of Oriental origin, being derived from the Arabic "koton" or "gootn."

Before taking up the ginning of cotton it is well to consider its principal characteristics. There are two general classes or distinctive kinds of cotton grown in the United States, "sea island" and "upland." Sea island cotton does not adhere to the seed, and the lint can easily be pulled off clean, leaving the seed perfectly smooth. The staple varies from $1^1/_2$ in. to $2^1/_4$ in. in length, and is of a light creamy silk color. While strong, it is finer than other kinds and being but about 0.00063 in. in diameter, has a more beautiful luster.

Upland cotton adheres to the seed, and appears to grow out of them more like wool from a sheep's back. The seed, after being divested of lint as well as possible, still have a woolly appearance, and in a great many varieties a greenish color, and hence upland cotton often referred to as "green-seed" cotton. The stable varies in length from $^5/_8$ in. to $1^1/_4$ in., and its color ranges from white to a creamy tint. The staple is inferior in strength to the sea island type and coarser, being 0.00076 in. in diameter. The fibers are soft, elastic, moist and pliable, but the natural twist is rather inferior in character to that of sea island cotton, being irregular.

Good commercial cotton must possess certain well-defined external and internal characteristics. The external qualities, which are apparent to the touch or visible to the naked eye, are:

a Length of fiber
b Fineness or smallness of diameter
c Evenness and smoothness
d Elasticity
e Tensile strength
f Color

The internal characteristics, which are discernable by a microscope, are:

a Hollowness, or tubular construction
b Natural twist, due to the collapsed tube
c Corrugated edges
d Moisture

These characteristics are necessary to constitute a good mature cotton fiber, are essential in effecting the close union of the filaments, and make cotton superior to any other fiber, vegetable or animal. And since the cotton fiber has such a delicate structure and great value, it is necessary that the machinery used in its ginning and cleaning be of such character that the least damage will be done to the staple in the process.

The first method to be employed in separating cotton lint from the seed was that of hand picking. The next method, originated in India about 300 B. C., made use of rollers, which when running close together would pull the lint through and leave the seed behind. The roller gin is now used principally for ginning sea island or long-staple cotton and has gone through a long process of development and improvement.

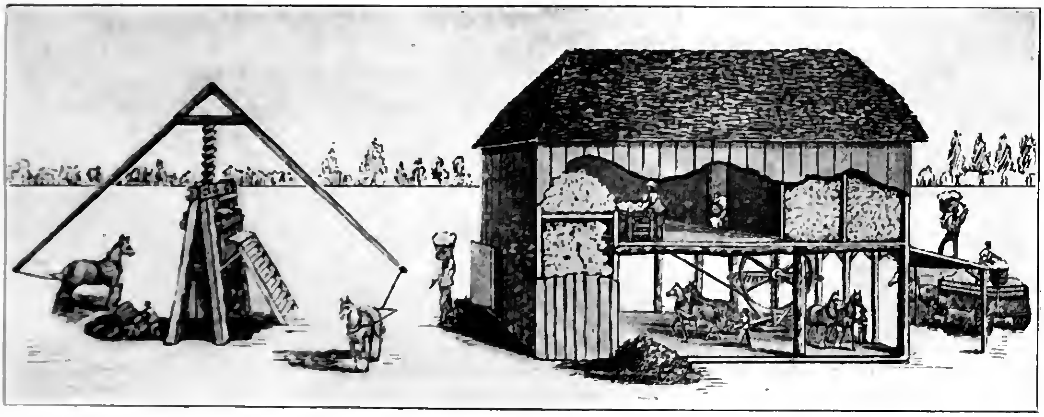

FIG. 1 EARLY TYPE OF GINNERY

In the United States the great problem that presented itself in the early days of the industry was that of removing the seed from the upland or green-seed cotton. The roller gin in its crudely developed state at that time would handle the sea island cotton to a certain extent, but was not adaptable to and suitable for the upland cotton.

In 1792 Eli Whitney, of Massachusetts, went by boat to Savannah, Georgia, and there developed the first cotton gin, for which a patent was granted him two years later. The original Whitney gin was a hand-power and hand-fed gin, consisting of a horizontal wooden cylinder about $7^1/_2$ in. in diameter and 2 ft. long, into which wire teeth were driven in rows spaced apart to admit the seed cotton but with the teeth in each row so close together as not to admit seed. The teeth were all inclined the same way, making an angle of 55 deg. to 60 deg. with a tangent at the point of entry. The

[1] Mechanical and Industrial Engineer. Mem. Am.Soc.M.E.

cylinder had suitable bearings at each end and a hand crank, and above and in front of the cylinder was a hopper to receive the seed cotton, while directly over it was a breastwork or stripping grate consisting of a timber lined with a metal strip having a series of slots through which the rows of teeth could pass, taking the lint cotton but obstructing the seed. The lint was removed from the teeth by means of a cleaner or brush consisting of four sticks with bristles and so constructed that it formed a tangential cylindrical co-acting surface of bristles rotating in an opposite direction to that of the teeth and much faster. It was driven by an endless belt and idler. The gin was not continuous in action as are the gins of today, but had to have its seed dumped from time to time as they accumulated.

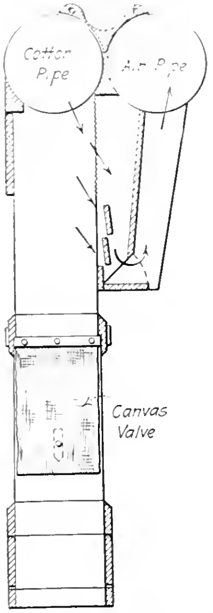

Fig. 2 Pneumatic Elevating System for Large Ginnery

Two years later—May 12, 1796—a patent was issued to H. Ogden Holmes of Augusta, Georgia, on a hand-fed and hand-operated gin similar to Whitney's, except that it was continuous in operation, being so constructed that the seed would shed out as fast as they were delinted. This was also the first gin to use metal disks or saws, which were mounted on a square shaft with the ends turned down for bearings and the saws separated by space blocks. The brush contained more than four bristle-filled sticks, and was driven in reverse direction to that of the saws and four or five times as fast. This gin would shed the seed continuously as fast as delinted, and the roll of cotton in the roll box would revolve just as it does in the saw gin of today.

A little later, larger power-driven gins were employed, Fig. 1, the transmission consisting usually of a large 8-ft. wooden bevel gear mounted on a vertical axis with an extended beam or arm to which a horse or mule was hitched, and a horizontal shaft with a wooden pinion worked in conjunction with the large bevel gear, on which shaft a 12-ft. band wheel was mounted and from which the gin was driven at from 200 to 300 r.p m. by means of a belt. In this system the gin was hand-fed from a platform above. The lint was discharged into a sack suspended beneath a hole in the floor back of the gin, sacking being the first system to be used in handling cotton in the market. Later, however, a lint room was built to receive the lint cotton, which was then carried out of doors, in baskets and put into a crude wooden press. This press was of very heavy mill construction, consisting of a single heavy box with discharge doors at the bottom and four large wooden corner struts or tension supports. An elevated platform was built of sufficient height to easily permit the placing of cotton in the press box from above, just below the overhead sills. The press screw was of wood and 15 in. in diameter with levers fixed to the top end and inclined downward to receive a rope to which a horse or mule was attached. Some presses had roofs over them, while others were left out in the open.

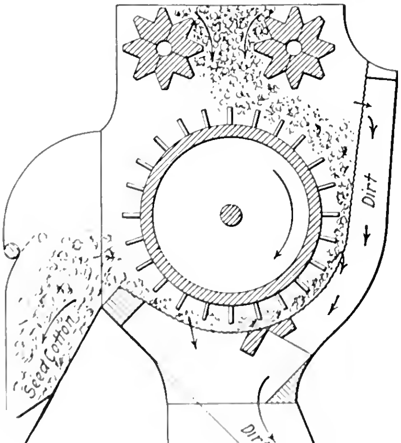

Fig. 3 Feeder for Ginning Roll Box

The ginning system was later improved by the addition of a mechanical feeder over the gin and a single lint condenser back of it, and also by the employment of the steam engine for motive power. As the demand for larger output grew the ginneries were increased to two and three stands and the presses made more modern by the use of a 5 in. steel screw. In some cases the presses were equipped with large steam cylinders 30 in. to 36 in. in diameter, which operated much more rapidly than the screw press. These small ginneries were commonly known as plantation gins and were a part of the equipment of each large plantation. As the cotton industry grew, however, and the large plantations were superseded by small ones, custom gins came into use, doing away with the plantation gin and compelling inventors to seek better methods of caring for larger capacities at the gins. At first belt carriers were installed back of each battery of gins, which received the lint from each of the single condensers and delivered it to the press box. This crude system however, was later replaced by a single lint flue receiving the lint cotton direct from the various gin stands—which were in batteries of from two to six stands—and delivering it to a single large lint condenser or bat former, which then delivered it to the press. The lint flues were first constructed of wood, but later sheet iron was used, the diameter being about 18 in. at the smaller end and increasing as gins were added.

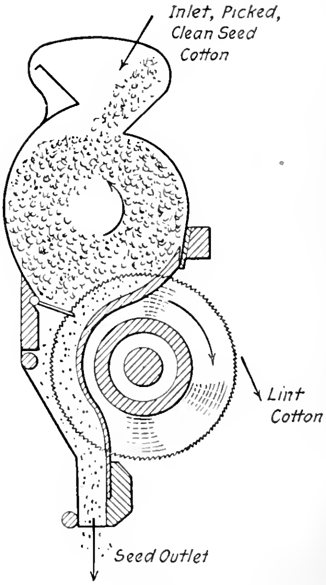

Fig. 4 Plain Gin

To care further for the large output of cotton at the custom ginneries, the revolving double-box press was developed. In this press one box acted as a receiving chamber from the condenser and was provided with a tramper or packer which packed 500 lb. of lint cotton in it, after which it was revolved around, bringing

the other (empty) box onto the receiving side while the one filled with cotton was pressed into a bale.

The standard cotton-bale boxes for presses are 27 in. by 54 in. by 10 ft.; the cotton is pressed from the latter dimension down to 36 in. and then six ties are put around it. Before being pressed, jute bagging is placed at the top and bottom of the cotton for wrappers. Upon releasing the pressure on the bale it usually expands from 40 to 42 in. making a finished bale 27 in. by 54 in. by 40 to 42 in. with a density of 12 lb. per cu. ft. A maximum pressure of 10,000 lb. is required in packing a bale of cotton in the receiving chamber and 70,000 lb. to press a standard bale.

Mechanical elevating systems were also developed for use in the large ginneries. The earlier designs were belt carriers, consisting of slats of wood nailed or riveted to two narrow belts, which would drag the seed cotton along from the point where it was fed on by hand to the point of delivery in the feeders. This process however, required too much human labor, and one comprising a suction fan with vacuum box and belt distributor was next devised.

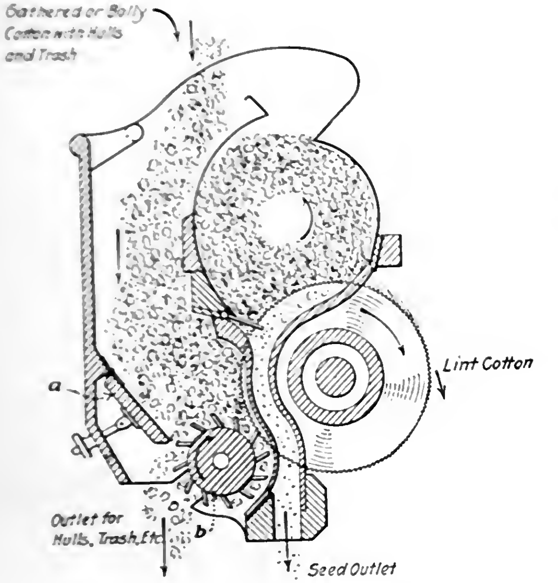

Fig. 5 Huller Gin

In this system the cotton was sucked from the wagon through a pipe to the vacuum box in which there was a wire screen to separate the cotton from the air, the cotton then falling on the spiked belt distributor below, by means of which it was delivered to each gin feeder. The screen area in these vacuum boxes was 1 sq. ft. of $^1/_4$-in. mesh screen wire to 14 to 20 saws. The pneumatic elevating system, Fig. 2, was also invented and consisted of a vacuum chamber or elevator chute over each feeder and gin. This chute consisted of a chamber 12 in. by 53 to 60 in. by 6 ft. high with an air and cotton pipe at the top, a screen box attached on the upper back side and a heavy 12 to 16-oz. canvas valve near the center. This valve was so constructed that when the suction was applied it would close and prevent leakage of air through the valve causing suction in the telescope pipe in the wagon. This would deliver cotton into the several elevator chutes and then periodically the air would be cut off by means of a valve trip, thus releasing the air suction, and the canvas valves would drop the cotton into the gin feeder. The screen in the pneumatic elevator to separate the cotton from the air is usually light No. 21 gage, $^1/_4$-in. mesh wire, and the screen area is about one square foot to 10 saws. The fans used in these two elevating systems are of the steel-plate centrifugal type, varying in size from a 30-in. fan for a two-gin installation to a 45 to 50-in. fan for six gins. The peripheral speed of the suction fan-blast wheels varies from 11,000 ft. per min. to 13,000 ft. per min., which maintains a vacuum of 14 to 16 in. of water.

Seed-Cotton Cleaners

There are many kinds of machines in use for cleaning seed cotton, but the general principle employed in them all consists of agitating the cotton on a wire screen of $^1/_4$ to $^1/_3$-in. mesh, permitting the dirt, sand, leaf trash and other foreign substances to escape.

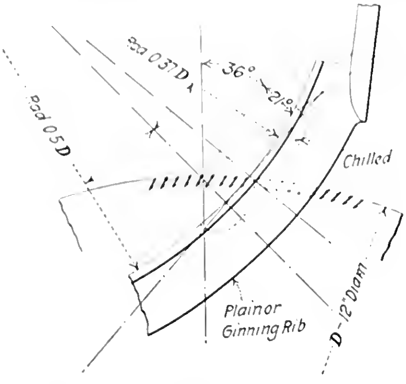

Fig. 6 Detail of Rib and Saw, Plain Gin

It is customary in some sections of the country, where climatic and other conditions interfere with the opening of the cotton boll, to provide a boll-breaking attachment to a cleaner. In some sections, where labor is scarce, the seed cotton is not carefully picked from the open bolls but is grabbed; that is, cotton, pod and all are pulled off in a mass. In such cases the cleaning is an important item, because if not carefully handled the cotton will be damaged in the process. Some cleaning machines therefore have a cylinder of saws to separate the seed cotton from the pod or broken bolls; but this process is best accomplished in the huller gin which will be considered later.

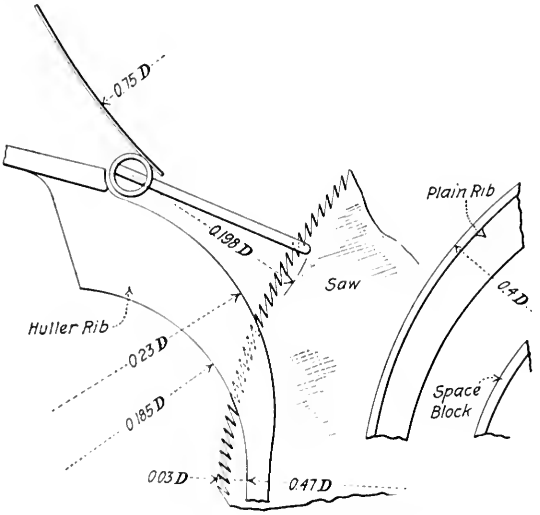

Fig. 7 Detail of Rib and Saw, Huller Gin

Feeders

The feeder receives the cotton from the pneumatic elevator or belt distributor above it, and delivers it in a uniform, even amount to the ginning roll box. There are two general types of feeders, The horizontal slatted-belt type that receives the cotton from the belt distributor or pneumatic elevator on a very slow-moving slatted belt and moves it horizontally up to a spiked drum or picker roller 9 in. to 11 in. in diameter, rotates 180 to 200 r.p.m. and is provided with a series of No. 8 spikes projecting 1 in. from the surface. These spikes lift the cotton over and throw it down

a chute into the ginning-roll box. Another general type, Fig. 3 receives the cotton from the elevator chutes or belt distributor on to two fluted rollers 5 in. to 6 in. in diameter rotating toward each other at $^1/_2$ to 1 r.p.m., slowly feeding the cotton down where it is taken off by a picker roller similar to the one previously described, and is then whipped around a $^1/_3$-in. mesh No. 16 gage wire screen that partly surrounds the picker roller at a distance of about $^1/_2$ in. therefrom, threshing the light leaf trash and sand out of it before delivering it to the ginning roll box for the next process. The latest improved feeders are effective cleaning machines.

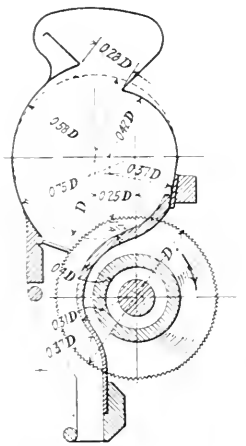

Fig. 8 Proportions of Plain Gin Roll Box

The Seed-Cotton Gin

The gin stand is the principal machine in the system as it performs the main work of separating the seed from the lint. There are two general types of saw gins, (*a*) the plain gin, Fig. 4, that gins only clean seed cotton that is substantially free from bolls and trash and is the original type used; and (*b*) the huller gin, Fig. 5, that separates the seed cotton from the bolls, burrs, leaf trash, dirt and other foreign substances in the front lower roll box, and then carries the seed cotton into the upper roll box where it separates the lint from the seed, thus performing a double ginning operation. The main working parts in both types of gins are the saws cylinder, roll box and a means of removing the lint from the saw teeth after it is separated from the seed.

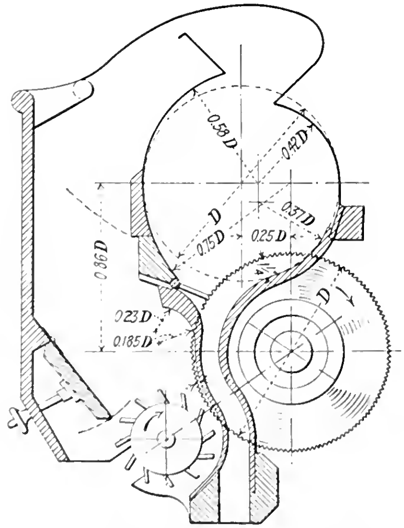

Fig. 9 Proportions of Huller Gin Roll Box

The Plain Gin

The standard saw cylinder is made up of a series of 70 to 80 steel circular saws 10 to 12 in. in diameter and 0.035 in. thick, mounted on a 2$^3/_{16}$ in. to 2$^7/_{16}$ in. mandrel and separated by wood or iron space blocks 0.6835 in. to 0.7396 in. thick and 4$^3/_4$ in. for 10 in. and 6 in. in diameter for 12-in. saws. The 12-in. diameter saw is considered best practice. The saw teeth all incline in the direction of rotation. There are seven teeth per inch, which are punched out and then filed smooth. This punching, however, crystalizes the saw steel to a certain extent and often results in defective teeth, with rough edges which are not noticeable to the naked eye but are very distinctly seen with a microscope. Some means should be devised for milling or grinding the teeth instead of punching to insure a perfect smooth tooth free from fracture and crystallization. The usual practice in the design of the tooth is to make both the front and back edges straight lines. In some cases, however, the front edges have been made straight and the back edges convex, resulting in what is known as "hog-back" teeth. The inclination of the teeth edges, Figs. 6 and 7, with a radial line through the point are 36 deg. for the front edge and 57 deg. for the back edge, the two edges making an angle of 21 deg. with each other at the point; this, however, may vary to suit certain working conditions later referred to. The saws rotate with a tooth travel of 1000 to 1250 ft. per min. for brush gins and 1400 to 1900 ft. per min. for air-blast or pneumatic gins.

The roll box, Fig. 8, consists of a series of ribs between the saws with a half-rib at each end, a back hollow above the ribs, an inlet opening or feed inlet at the top, a cover on the front side with a seed grate attached, and a shield or cover for the exposed portion of the saws below the roll box. In the development of the gin it was found by experiment that the process of ginning worked best by placing the roll box above the saws, thus permitting the roll of cotton to rest upon them, Fig. 4; the saw teeth in taking hold of the cotton fibers would cause the whole mass of cotton to revolve in reverse direction, and usually at about a fifth of their velocity, depending upon the quantity of cotton in the roll box and the hardness of the roll.

The cotton roll is theoretically round, Fig. 8, and the same diameter as that of the saws; but due to the following necessary working conditions its perfect roundness is distorted.

a The saws are caused to project up into the roll box from 1$^1/_{16}$ in. to 1$^5/_{16}$ in., 1$^3/_{16}$ in., being considered the best practice. The cotton roll merely rests upon the saws, and the saw teeth, Fig. 4 only project into it. The cotton roll itself when rotating, is hollow, due to centrifugal force, and the cavity in the center is from 25 to 50 per cent of its diameter. It is best practice for the roll of cotton in the roll box to be as soft as possible, that is, with as large a cavity as possible, because this prevents the cotton fibers from wedging into the throats of the saw teeth, cutting and knapping the fibers, and also permits the fibers caught by the saw teeth to disentangle from the mass of the roll without breaking off; this precaution is especially necessary when the saw teeth are traveling at a high velocity.

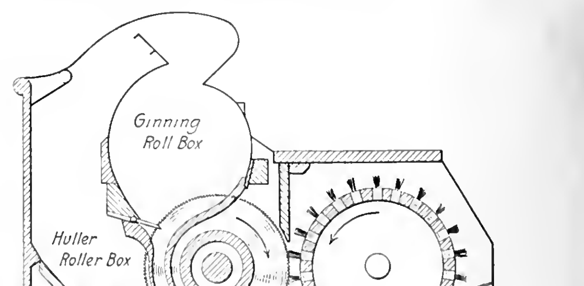

Fig. 10 Brush for Removal of Lint from Saw Teeth of Huller Gin

b The rib is tangent to the theoretical roll at its lower side; but the curve of the rib cuts up into the theoretical roll with a radius of 37 per cent of the saw diameter *D*, and at the upper edge of the

rib, from $1^1/_2$ to 2 in. above the point where the saw teeth pass through, there is an offset dropping the working line back tangent to the theoretical roll, to permit the cotton fibers that were pulled between the ribs and not carried away by the saw teeth, Fig. 4, to free themselves from the ribs. The ribs are usually made of cast iron and at the points where the saw teeth pass between them they are chilled, for an inch or so each way, Fig. 6, thus making a hard working surface that exhibits very little wear. The space between the ribs at the point where the teeth pass through is 0.125 in. wide and increases in width in each direction therefrom. The wearing surface of the rib as well as the edges are ground smooth and polished. The lower end of the rib is extended downward beyond the circle of the saw and attached to a rail or bar and the upper end extended just above the offset to attach likewise to a bar or rail, while the inner surface is ground to the curvature of the theoretical roll.

c The back hollow begins at the upper end of the rib, tangent to the theoretical roll, and curves inward and upward with a radius of 42 per cent of the saw diameter *D* to give the roll a proper density at the ginning point below and also pack it just before reaching the inlet opening at the top. This opening is 28 per cent of the saw diameter *D*, and is for the purpose of admitting cotton into the roll box at the top when operating as a plain gin.

d The front roll curves are the reverse of those of the rib and back hollow. The front is tangent to the theoretical roll at the intersection of the horizontal center line with it, and curves outward therefrom toward the top, to allow freedom for the admission of cotton, with a radius of 58 per cent of the saw diameter *D*. It also curves out from the center line toward the bottom with a radius of 75 per cent of the saw diameter *D*, to allow the roll to loosen so the ginned and cleaned seed will drop out. Near the bottom of this curve of the front there is a seed grate consisting of a pivoted rod with No. 8 fingers projecting out between the saws and extending $^1/_4$ in. inside of the saw-tooth curve. By raising the fingers or grates they press up against the bottom of the cotton roll and retard the shedding of the seed, and by lowering them the seed are shed free; if lowered too much, however, the seed are released before the lint is entirely removed, Fig. 4, the ginning being thus regulated. The seed are shed out in the course of their travel from the seed grate to the point where the saw teeth pass between the ribs, the seed that are free from lint dropping out of the roll on to the ribs below and escaping to the seed conveyor below. The center of the roll box is not directly above the center of the saws because it would cause the ribs below to be too flat and not permit the seed to slide down out of the way, therefore the center of the roll box is 25 per cent of the diameter *D* in front of the vertical center line. The exposed portion of the saws below the roll box is covered with a shield to prevent injury to the operator; some roll boxes, however, have fronts that extend down and cover the exposed saws.

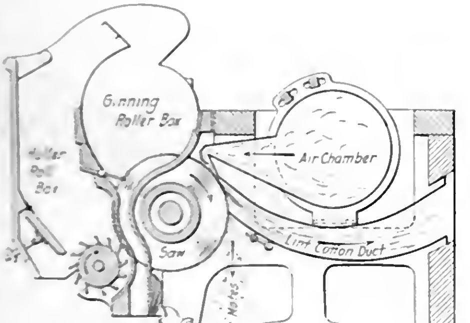

Fig. 11 Air-Blast or Pneumatic Gin

The saw teeth in traveling under the cotton roll take hold of some of the fiber and carry it between the ribs, leaving the seed in the roll box to be shed out as above explained. Each saw tooth that is loaded with lint cotton, amounting to from 0.000005411 lb. to 0.000004466 lb. per tooth for brush gins and from 0.000004025 lb. to 0.00000375 lb. per tooth for air-blast or pneumatic gins, being 100 to 160 fibers per tooth based on 29,000,000 fibers per pound, must be unloaded or cleaned before it returns to the roll box again. The removal of the lint from the saw teeth is accomplished by means of a brush, Fig. 10, consisting of a series of $^3/_4$ by 1-in. sticks, usually 22 in number, in which bristles are inserted usually projecting 1 in. from the stick. These sticks are mounted on a series of drum heads on a shaft $1^{15}/_{16}$ to $2^3/_{16}$ in. in diameter. The outside diameter of the brush cylinder is usually 15 in. Each brush has four wings 1 in. by 6 in. on each end head. In the operation of the brush gin the brush is set up to the saw cylinder so that the tips of the bristles overlap the saw teeth just $^1/_{16}$ in., and then caused to rotate in the reverse direction to that of the saws and at a peripheral speed of 6300 to 6900 ft. per min., or approximately six times as fast as the saw-tooth travel. When the bristles are new they have a wiping effect on the saw teeth, but after considerable use the tips wear off to such extent that they do not touch the saw teeth, and it is only the air blast generated by the brush that removes the lint. At the rear of the brush there is a board or sheet-metal cut-off, similar to that of a fan. And just above and between the saw cylinder and the brush there is a parting board that directs the air current on to the saw teeth, removing the lint and at the same time deflecting the motes out of the general current by centrifugal force with the assistance of the mote board, while the lint is blown into the lint flue below. The mote board is just below and between the saw cylinder and the brush, and is adjustable so that in the regulation thereof the motes just pass out while all of the lint cotton is caught in the lint flue. The usual air current or pressure produced on the saw teeth by the brush varies from 5 to 6.5 in. of water, and in its travel to the lint-flue main body it expands until the pressure in the flue is $^3/_8$ to $^1/_2$ in. of water.

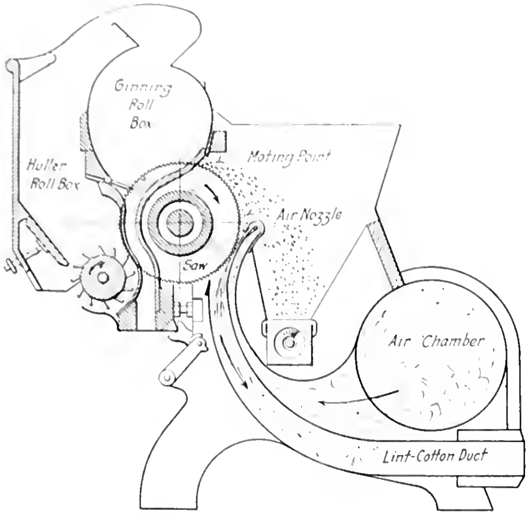

Fig. 12 Another Type of Pneumatic Gin

The discovery that the air blast generated by the brushes had such an important part in removing the lint from the raw teeth led to the discovery of the pneumatic gin. Figs. 11 and 12, show two different types of this gin. One (Fig. 11) discharges the motes below, while the other, (Fig. 12) discharges them over the top of the air lip. In the early air attachments the discharge-nozzle opening was $^7/_{16}$ in to $^1/_2$ in. wide and extended 1 in. beyond each end saw; after continued development, however, these openings were reduced to $^1/_4$ in. to $^5/_{16}$ in. The air blown from the lip

opening continues to hug the sheet that leads to the lint-flue opening, and this sheet is brought up to within $^1/_{32}$ in. to $^3/_{32}$ in. of touching the saw teeth. The lint opening is just wide enough to receive all the air discharged from the air nozzle, and in addition thereto a small amount of the outside air is injected by the dynamic action of the air current. There is thus a slight current from the outside leading into the lint flue to insure that there will not be a loss of lint fibers on the outside, which would be the case if the reverse action took place. The air pressure at the nozzle outlet is usually from 8 in. to 12 in. of water. The various pressures for other points in and around the air nozzle for the two types of gins are as shown in Figs. 13 and 14. The pressure in the lint flue at the rear of the gins varies from 0.7 in. to 1.0 in. in the rear of the gins to 0.5 in. to 0.65 in. in the lint-flue uptake to the condenser.

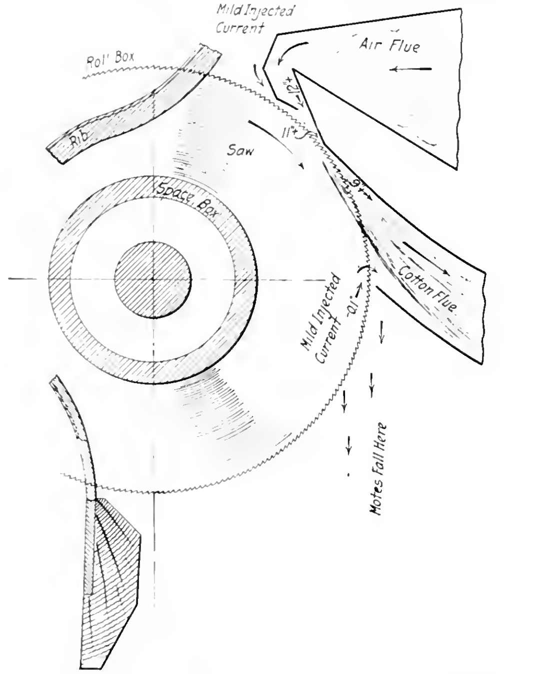

Fig. 13 Air Pressure at Various Points in Pneumatic Gin Shown in Fig. 11

The Huller Gin

The operation of the huller gin is very similar to that of the plain gin, in that the saw cylinders and the method of removing of the lint therefrom are the same. The roll-box construction is also the same, except that there is an additional huller roll-box in front of the ginning roll-box, Figs. 5 and 9, for separating the seed cotton from the burrs, sticks, trash, etc., and the cotton is delivered into the huller roll-box first, Fig. 5, and from there is carried up into the ginning roll-box by the saws; hence the feed to the ginning roll-box is from below instead of from the top, as is the case with the plain gin. The huller roll-box, Fig. 5, consists of a chamber in which the cotton is fed, and this chamber has a hinged removable front cover *a* with an inclined sheet or board for regulating the refuse discharge, and a huller picker roller *b* $2^1/_2$ to $4^1/_4$ in. in diameter with 10 to 16 longitudinal rows of No. 8 spikes set at an angle of 30 deg. to radius of point where they enter roller. These spikes are alternated and in circular rows of 5 to 8 spikes between each pair of saws, and project out $^3/_4$ in. to 1 in. from the roller, which rotates at from 300 to 700 r.p.m. There is also a set of huller ribs, Fig. 7, to prevent the hulls and trash from being carried into the upper or ginning roll box, thus performing a double ginning process. The huller ribs partly surround the huller picker roller, Fig. 9, and the outer or working surface of the rib is $^1/_4$ to $^3/_8$ in. from the tips of the saw teeth; just below the seed grate the rib curves out and is fixed to a rib rail or bar.

In the operation of the huller gin the cotton, Fig. 5, is fed into the huller roll box, the spiked picker roller rotating in the reverse direction to that of the saws, spikes inclining backward. The cotton is thus thrown on to the saw teeth and carried up into the ginning roll, leaving the trash, a part of which is shed out; but as the quantity increases, the box front is swung out by hand, discharging the foreign substances. When there is a large amount of trash the picker roller is pulled out from the ribs and the inclined board moved back, thus permitting the trash to shed out in front of and behind the roller; but if there is only a small quantity, the huller roller should be set up close to it, to prevent the dropping of locks of cotton. The huller ribs are spaced sufficiently apart at the point where the teeth pass between to permit the seed cotton to pass through into the ginning roll box. The lint is removed from the saw teeth by means of a brush or current of air as has been described for plain gins, and the operation of the ginning roll box in shedding the seed is the same. The lint cotton is removed from the saw teeth and passed into the lint flue which has inlets from the various gins set in battery. The size of the lint flue varies according to the number and size of gins, the general practice being to have about three square inches per saw.

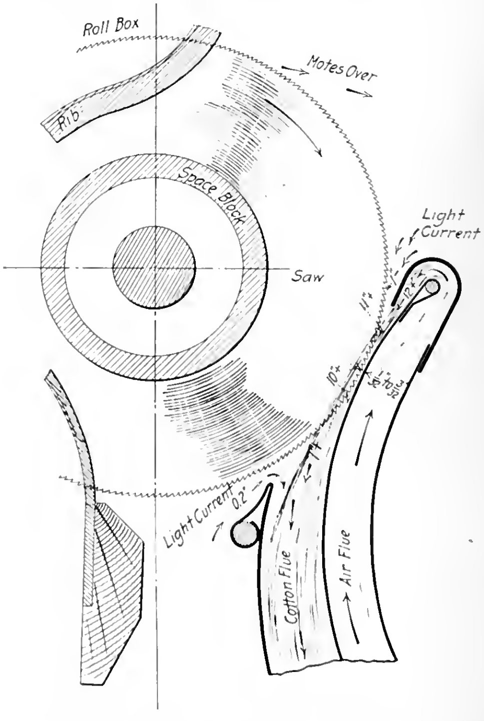

Fig. 14 Air Pressure at Various Points in Pneumatic Gin Shown in Fig. 12

The Condenser

The lint flue delivers the cotton into the condenser which consists of a large horizontal drum covered with 8-mesh No. 21 wire screen. The drum is usually 54 in. long, the same as the cotton bale, and its diameter is usually 30, 40, 50, 60, or 72 in. respectively, for 100, 175, 250, 325 or 400 saws. The screen drum, Fig. 15, is mounted in a housing that spirally circumscribes it with air outlets at the ends and two doffing rollers at the discharge side, the lower one having flaps of thin $^3/_{32}$-in. light cloth-backed rubber. The rollers receive the lint cotton from the drum and deliver it on the lint slide and then into the receiving chamber of the press box. The portion of the screen drum exposed to the cotton air current is about 75 per cent, and there is 1 sq. ft. of screen provided for every 5 to 6 saws; but when the drum rotates it travels at a rate of speed of 50 to 80 ft. per min. for the smallest up to the

(*Continued on page 242*)

Reduction of Fuel Wastes in the Steel Industry

By F. G. CUTLER,[1] ENSLEY, ALA.

The paper sets forth the economy of utilizing blast-furnace gas, at one time considered to be of little material value, in reducing the wastes of the steel industry. It is shown how the quantity of gas to be expected in the production of one ton of pig iron may be computed, and the uses to which this gas may be put are analyzed quantitatively. A heat balance, based on the production of one ton of pig iron is presented, showing the sources of heat and the requirements for blast-furnace and steel-mill operation. It shows that the total heat from the by-products of a ton of pig iron is more than sufficient to finish a ton of steel. The heating requirements are not met by the tar and by-product gas, although the average power requirements are more than met by the blast-furnace gas and coke breeze. It therefore becomes desirable to reduce the heating requirements for the production of steel by using more efficient heating furnaces, and to conserve all possible heat by charging hot steel into the soaking pit and reheating furnaces, in order to reduce the quantity of fuel required for supplementary heating.

In order to show the relative proportion of the energy in the shape of heat or power required for the manufacture of steel that is utilized from the fuel by-products of the manufacturing process, the following figures have been prepared showing the quantity of heat derived from the by-products of the manufacture of pig iron.

In the production of one ton of pig iron, from under 1800 to over 3000 lb. of coke are used, this variation being due to difference in metallic content of the charge, condition of the furnace lining, quality of coke, etc. The heat energy of this coke is utilized in the reduction of the ore to pig iron and changing the impurities to a slag, a part is lost in radiation, and approximately half is delivered at the top of the furnace in the shape of gas for use under boilers for the production of steam, or in gas engines for the production of power. The gas has also been used in soaking pits, in by-product oven heating, ladle drying, etc., and other uses have been proposed, but by far the greatest quantity has been used under boilers.

It has been only within the last few years that blast-furnace gas has been considered to have any material value. In the past there has been no recognized method of determining whether or not a blast-furnace plant has been guilty of wasteful practice, or if guilty, what the extent of this waste might be, and it is the intention of this paper to propose a standard method of comparison of total combustion efficiency, both with the idea of determining, for any particular plant, the relative efficiency, from day to day or month to month, as well as for the comparison of one blast-furnace plant with another, for the information of the management and the engineers in determining the necessity for improvement in equipment or personnel.

Heat Available from the Blast Furnace

In proposing this standard comparison reference is made to Fig. 1 which is taken from Mr. Brassert's paper on Modern Blast Furnace Methods, published in the year book of the American Iron and Steel Institute in 1914. This chart shows the effect of variation in coke rate upon the heat value of blast-furnace gas at 62 deg. fahr. As blast-furnace gas leaves the top of the furnace it usually has a temperature of from under 300 to over 600 deg. fahr., generally averaging about 400 deg. fahr. At this latter temperature, the sensible heat of the gas is equivalent to about 8 B.t.u. per cubic foot of gas at 62 deg. The B.t.u. per cubic foot of blast-furnace gas according to Brassert is $62.5 + 0.016R$, where R = lb. of dry coke per ton of pig iron; and including sensible heat of the gas at 400 deg. fahr. would be equal to $70.5 + 0.016R$. The cubic feet of gas per ton of pig iron (as shown by Brassert) is equal to $71.4R$, so that in the top gas from a furnace at 400 deg. fahr. the B.t.u. per ton of iron is $1.142R^2 + 5033.7R$. Brassert also gives the cubic feet of air per pound of coke equal to $51.4R$, so that both gas production and the blast requirement bear a direct ratio to the coke consumption of the furnace per ton of iron. The figures given in Mr. Brassert's paper, so far as the author has been able to discover, are applicable to all blast furnaces using coke as fuel

Heat Required for the Stoves

The blast is heated in stoves under pressure, and the heat required per cubic foot of blast is proportional to the rise in blast temperature in the stove, and inversely proportional to the efficiency of the stove, which is usually considered to average 60 per cent. After the necessary gas is used to heat the blast, the remainder can be measured in the shape of power. Any increase in stove or boiler efficiency or reduction in leakage of gas, etc., is reflected in increased surplus power, and as we are largely interested in the surplus power, after the blast furnace requirements are satisfied, any error in the assumptions relative to the efficiency of the stoves is of minor importance, particularly as the stoves use the smaller fraction of the total. The blast supplied from the blowing engines is heated by compression to about 150 deg. fahr., varying somewhat with blast pressure, etc., and is usually heated in the stoves to from 1150 to 1350 deg. fahr. In the following calculations it has been assumed that 0.02 B.t.u. are required per cubic foot of blast per deg. fahr., that the blast is heated in the stoves to 1250 deg. fahr., that the average overall stove efficiency (i.e., ratio of heat given to the blast to the heat in the gas) is 60 per cent and that 55 cubic feet of blast are heated per pound of coke charged.

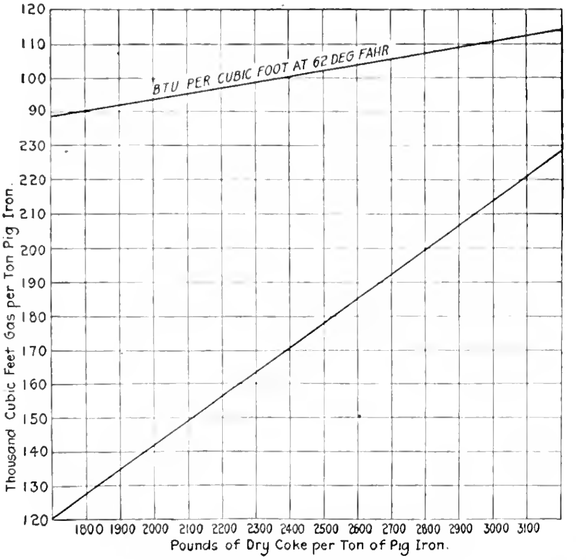

Fig. 1 Effect of Coke Rate on Production of Blast-furnace Gas

The heat required in the gas for heating the blast for one ton of pig iron to a temperature of 1250 deg. fahr. can therefore be expressed by the following formula where H = B.t.u. per lb. of coke burned in the blast furnace.

$$H = \frac{(1250 - 150) \times 0.02 \times 55R}{0.60} = 2020R$$

The heat in gas per ton product after the blast is heated is, therefore, $1.142R^2 + 3013.7R$. For other top temperatures and blast temperatures the constants will change slightly.

---

[1] Chief of Bureau of Steam Engineering, Tenn. Coal, Iron & R.R. Co.

Abstract of paper to be presented at the Spring Meeting, Atlanta, Ga., May 8 to 11, 1922, of The American Society of Mechanical Engineers. Copies of the complete paper may be had upon application. All papers are subject to revision.

Heat Required for Gas-Fired Boilers

In order not to enter into the discussion of the relative merits of steam vs. gas engine, surplus uncooled gas, after the stoves are heated, will be assumed to be used under boilers. In one boiler horsepower-hour there are 33,305 B.t.u., and assuming that the "standard" efficiency of blast-furnace-gas-fired boilers is 66.6 per cent, in one boiler horsepower-hour $\frac{33{,}305}{0.666} = 50{,}000$ B.t.u. would be required in the gas, so that the boiler hp-hr. per ton would be $\frac{\text{Surplus B.t.u. per ton iron}}{50{,}000 \text{ B.t.u.}}$. As the blast furnace product is usually expressed in tons per day the average boiler horsepower per hour generated from blast furnace gas under the above conditions can be expressed by the formula:

Average boiler horsepower per hour per ton of pig iron per day

$$= \frac{1.142R^2 + 3013.7R}{50{,}000 \times 24}$$

In assuming the standard efficiency of 66.6 per cent for boilers and 60 per cent for stoves, it should not be understood that these are the maximum efficiencies that can be attained, but rather that they are taken as a standard for comparison and represent average practice that can be maintained in a fairly modern plant which is correctly designed, and which is operated by reasonably intelligent men.

Using the above, Fig. 2 has been prepared. This chart also shows the per cent of top gas required for heating the blast to an average of 1250 deg. fahr. with the stoves of 60 per cent total efficiency. This chart can be used by the blast furnace superintendent or engineer to determine the horsepower that should have been generated from gas for any period. From the actual results as shown by a meter on the boiler feed line, after deducting an allowance for steam generated by coal firing (usually small) or for gas used by gas engines, it will be possible to determine whether the total efficiency, including stoves and boilers, is above or below the standard.

The following table shows the boiler horsepower-hours per ton of pig iron for several coke rates as calculated from the above formula.

Pound of Coke per Ton	Boiler-Horsepower-Hours per Ton Product	Boiler-Horsepower-Hours per Ton per Day
2000	211	8.8
2200	242	10.1
2400	276	11.5
2600	310	12.9
2800	318	14.5
3000	386	16.1

To furnish the blast to the furnace with either high-pressure condensing, turbo-blowers or reciprocating steam engines requires about 70 boiler hp-hr. per ton of coke burned in the blast furnaces, and to operate the various furnace auxiliaries, such as pumps, air compressors, steam bells, mud guns, hoists, etc., requires from 15 to 25 boiler hp. per ton of product, so that after the furnace requirements have been met, there is available for the generation of power from 100 to 250 boiler hp-hr. per ton of pig iron, depending on the coke burned in the furnace.

At 2 kw. per boiler hp-hr., this means that from 200 to 500 kw-hr. per ton of pig iron is possible with steam equipment from the surplus gas from the blast furnaces.

Heat Required for Manufacture of Steel from Pig Iron

The manufacture of steel from pig iron in the open hearth requires heat for melting scrap and fluxing the impurities, and power for the various operations incident to this process. The quantities of heat and power required vary materially with different plants on account of difference in equipment, practice, etc., but for the purpose of this paper it will be assumed that a ton of ingots requires one ton of pig iron plus enough scrap to offset the losses and this work requires from 5,000,000 to 9,000,000 B.t.u. and an expenditure of from 20 to 30 kw-hr. per ton. This ton of ingots will make about 0.85 ton of blooms, and the heating in soaking pits will require from 1,500,000 to 3,500,000 B.t.u. per ton of steel depending upon the temperature of the steel arriving at the pits, rate of operation etc., and the rolling of the ingots into blooms will require from 40 to 60 kw-hr. per ton. From the blooming or slabbing mill the material, usually reheated at an expenditure of from 2,500,000 to 6,000,000 B.t.u. per ton, is furnished to finishing mills, the power required, depending on the reduction of section, temperature of rolling, etc., varying from 35 to over 300 kw-hr. per ton.

Utilization of Industrial Wastes

Waste heat from open hearth and heating furnaces and kilns is utilized for the production of steam, and otherwise waste steam is utilized in low or mixed pressure turbines for the production of power, but as these subjects have been discussed many times, and are not peculiar to the steel industry, they will not be discussed except to say that while these economies are many times worth while in existing plants, very few new installations as designed include waste-heat boilers with furnaces, or low-pressure turbines as integral parts of new power plants.

Surplus by-product gas, after the ovens are heated, is sold for use as domestic fuel, etc., replacing natural gas, water gas, etc., and is used in the steel plant for melting steel in the open hearth, and for various heating operations in the steel industry. In former years this material was considered as having only nominal value and it was but rarely that any attempt was made to utilize it efficiently.

With the advance in fuel prices, shortage of natural gas, etc., and also largely due to special heating requirements connected with the manufacture of artillery and ammunition during the war, a number of combustion systems were developed that by more or less accurately regulating the proportion of air to gas have greatly increased the combustion efficiency of heating furnaces, and the control of combustion has been found of great importance in the maintenance of economy.

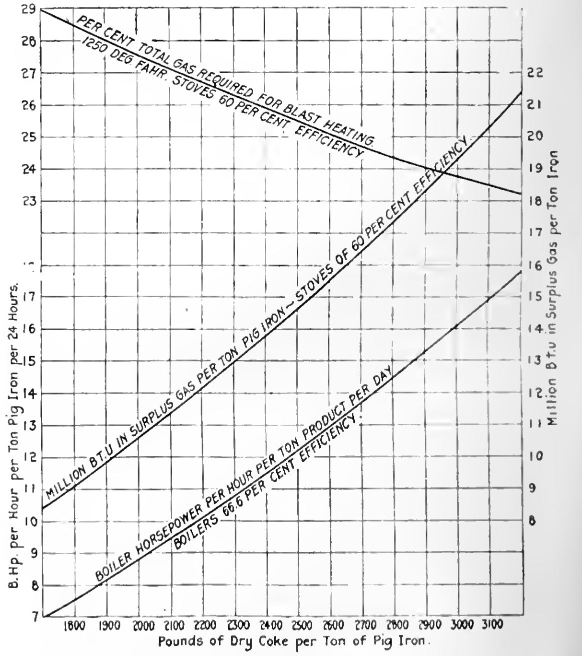

Fig. 2 Effect of Coke on Production of Power from Surplus Blast-furnace Gas

Dust coke breeze, from the coke plant (i.e., the material through a $1/8$-in. screen), is used to cover molten pig iron in transit from the furnaces and in making bottoms of soaking pits and heating furnaces. A great deal of this material which was thrown away or more or less inefficiently burned on hand-fired grates or, by mixing with slack, on mechanical stokers, is now more efficiently burned by itself, on traveling-grate forced-blast stokers.

Tar, either before or after the creosote oils have been removed, has been found to be a very good fuel for open-hearth furnaces,

Hydroelectric Installation on the Kern River

Two Turbo-Generators Arranged for Dual Operation at Either 50 or 60 Cycles—Unique Equipment for Efficient Use of Water Supply

By ELY C. HUTCHINSON,[1] SAN FRANCISCO

As the Kern River No. 3 Plant of the Southern California Edison Company marks the most important forward step in hydroelectric practice in recent years, a brief review will be given of the reasons leading to its development.

The plant is required to supply 60 cycle current for pumping plants to irrigate the growing crops in the San Joaquin Valley during the summer season, when the demand in Southern California is comparatively low. With the approach of winter, the pumping load, and with it the demand on the 60 cycle system decreases, while at the same time, the demand on the 50 cycle in Southern California increases. To meet this condition the plant must be connected into the general transmission system supplying the Southern California territory. This dual requirement is further complicated by a widely varying seasonal flow of the river with no opportunity for storage.

The power house is a reinforced concrete building 88½ft. wide and 130 ft. long, situated on the bank of Kern River. Tail water from the turbines is returned directly to the stream. The generator equipment consists of two 17,500 kva. General Electric Company vertical units, operating 3-phase at 11,000 volts for 60-cycle and 10,000 volts for 50-cycle current. They are provided with Reist spring type, water-cooled thrust bearings for supporting the entire rotating element inclusive of the hydraulic turbine runner and shaft. As is explained later, the turbines are designed so that an uplifting force is produced within the casing, thus reducing the load on the thrust-bearings.

Fig. 1 Exterior of Power House

The hydraulic turbine and their auxiliaries are of particular interest, as they are operating under the highest head ever attempted with turbine construction, and contain many novel features essential to success under the conditions. The operating requirements may be summarized as follows:

Effective head—780 ft. to 820 ft.

Water quantity—variable, from full supply for two units to less than sufficient for one under full load. No storage.

Generating frequency—either 50 or 60 cycles. Both units can be operated at 60 cycles, both at 50 cycles, or either unit can be operated at 60 cycles and the other at 50 cycles.

Speed—for 60 cycles, 600 r.p.m. For 50 cycles, 500 r.p.m.

The operating guarantees were:

Capacity—22,500 hp. per unit for either 50 or 60 cycle operation. (They are however operated almost continuously at 25,000.)

Efficiency—90 per cent maximum, either at 50 or 60 cycles.

Maximum speed rise—full load rejection, 60 cycle, 21 per cent, 50 cycle, 29 per cent.

Maximum pressure rise—full load rejection, 50 and 60 cycle, 20 per cent.

The turbines were designed and built by the Pelton Water Wheel Company's San Francisco Works. They are of the vertical type as shown in Fig. 2.

The casings are of cast steel, made in halves and bolted to a cast-steel speed-ring made in one piece. The casing covers are made of cast iron. The upper cover is constructed to support the turbine bearing, which is of the external babbitt-lined type. Leakage from the inside of the turbine casing is prevented by a stuffing box of unusual design.

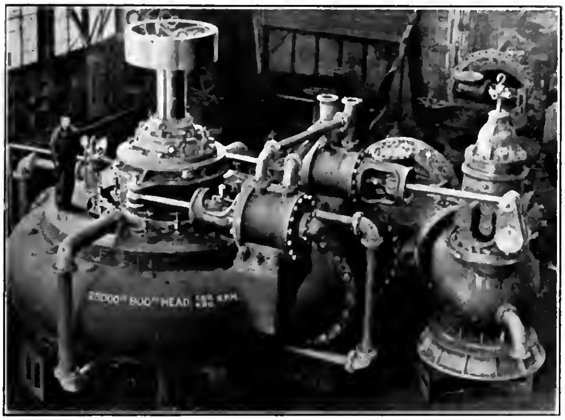

Fig. 2 Turbine in Place but Generator Not Connected

Owing to the high internal pressure and high rotating speed of the shaft, it was necessary to make special provisions for cooling the stuffing box. This was accomplished by fitting a water-jacketed, renewable wearing-sleeve over the shaft, and arranging to pack the stuffing box only loosely with specially designed metallic packing-rings. Any possible water seepage is drained off to tail water by means of an automatic ejector device.

Two interchangeable bronze runners are provided for each unit, one for 50 and the other for 60-cycle operation. These runners may be changed and the unit put back on the line in twenty hours by means of an interesting set of devices, for which patent application has been made. The procedure is as follows:

The runners fit on a tapered extension of the main shaft, which is hollow. A special portable hydraulic jack, which connects rigidly to the shaft, is used to force the runners on or off. The draft tube has two removable cast iron sections, each permanently provided with 4 roller-bearing car-wheels. These sections are lowered to rails set into the floor, after which they are rolled out or the way to give free access to the runner. All parts are raised of lowered by the power house crane with the hoisting cable passing through the hollow shaft.

One of the draft-tube sections acts as a carriage for the runner, which is thus wheeled to an open hatchway. Here the change is made from 50 to 60 cycle, or vice versa, with the station crane,

---

[1] Engineer, Pelton Water Wheel Co.

Abstract of a paper presented at a meeting on March 23, 1922, of the San Francisco Section of The American Society of Mechanical Engineers.

The new runner, on its carriage, is then wheeled to position below the turbine casing and hoisted into place. The change of runners is made without disturbing the gate-rigging or the guide-vanes, which are carried in grease-lubricated bronze bearings at both ends.

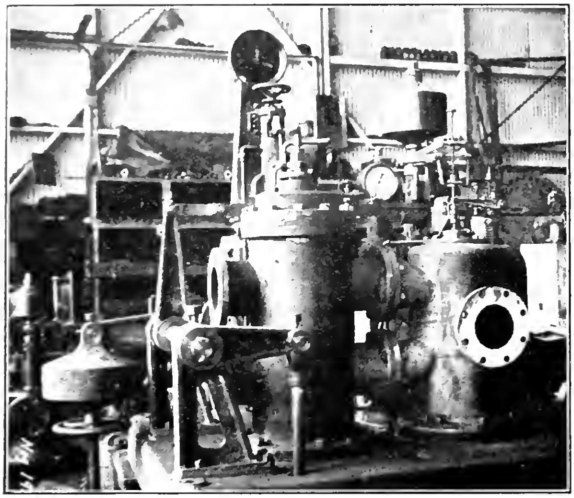

Fig. 3 Shop Assembly of Governor

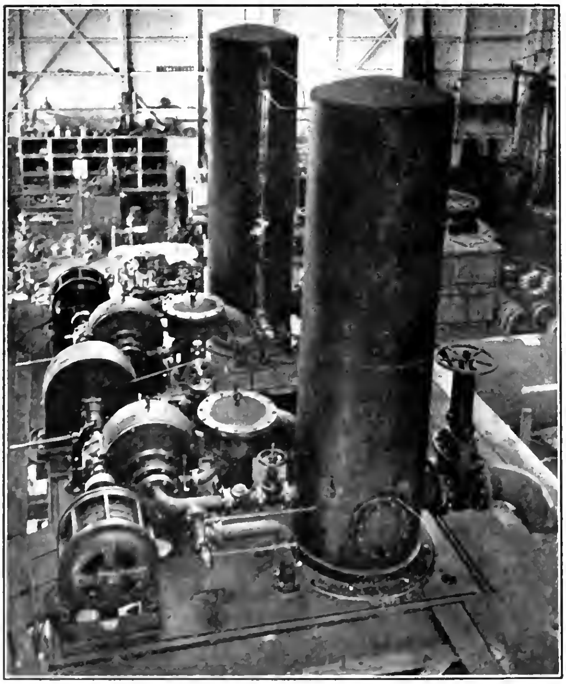

Fig. 4 Shows Assembling of Pumping Equipment, etc., for Oil-Pressure System Note Between the Two Motors the Impulse Wheel Which Takes Over the Pumping Load in Case of Momentary Failure of the Motors

On account of the high-operating head, the design of the water-seal rings between the rotating runner and the turbine casing called for careful study. It was finally decided that all seal-rings should be made removable and renewable, whether on the runner or in the casing covers. Straight face concentric clearance rings of rolled steel are attached to the runners, and bronze matching rings were placed on the casing covers. The control of pressures on the upper and lower faces of the runner and also the resultant hydraulic uplift for relief of the thrust-bearing load is automatic.

Further, when operating turbines under heads as high as used at Kern River No. 3 plant it is absolutely necessary that a thoroughly reliable and efficient brake be installed as a part of the equipment. It takes very little water at such high heads to develop sufficient power to keep the turbine rotating at full speed without load. Then if the guide vanes become worn and possibly slightly bent through closing on some obstruction, it is conceivable that enough leakage would occur actually to prevent closing down with the governor, were no brake available.

The brakes on the turbines of this plant are of the post type lined with a specially made wire-inserted asbestos-stitched fabric. They are hand operated from the main floor. From full speed of 600 r.p.m. the brakes will bring the rotating element to a full stop without undue effort in less than three minutes and in an emergency can be operated much more rapidly.

The governors are of the Pelton vertical-spindle belt-driven floating lever, actuator type taking oil pressure from a central system and delivering it to the servomotors, which are mounted rigidly on the turbine casing. The actuators operate on the open sump system, with enclosed centrifugal elements and dash-pot compensation. The shop assembly of the governor is shown in Fig. 3.

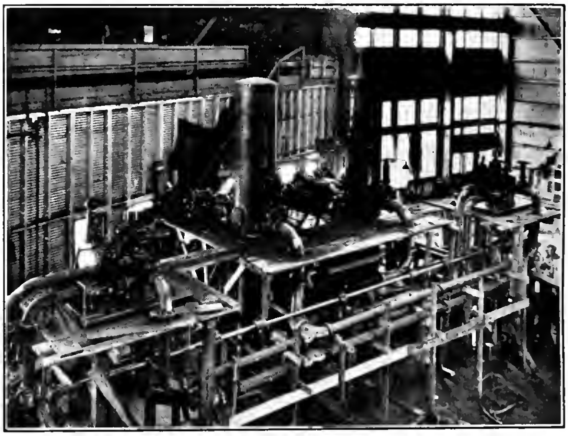

Fig. 5 Complete Shop Assembly of Governor and Oil Pressure System

A mechanical synchroscope and gate-opening indicator makes it possible to synchronize the valve positions in both governor actuator and hand control so that there will be no surging movement of the turbine-gate mechanism when switching from board to governor operation, or vice versa.

The pressure oil system is in duplicate, each side being of sufficient capacity to operate both main turbines at one time. The arrangement as shown in Fig. 4, includes two oil pumps of the Pelton rotary two-stage or series type. Shop assembly of governor and oil-pressure system is shown in Fig. 5.

Normally electric motors are used for operating the pumps. The arrangement is such, however, that if, for any reason the electric motor fails, the nozzle of a water motor automatically opens and the pump continues in service. The pump is thus made to operate continuously. This does not have any bad effect upon the oil however, for, when the pressure in the accumulating tanks reaches a predetermined maximum the pumps are automatically unloaded.

The equipment of the turbine and governors for the most efficient use of the available water supply is unique. About 300 sec. ft. of water is required to supply each turbine unit at full load. The stream flow varies with the season and at times is not sufficient for fully supplying one unit. From this minimum the quantity increases gradually to 600 sec. ft. or more. As there is

no storage available special apparatus was desired for automatically making use of the water supply to best advantage.

For periods when the water is more than sufficient for one unit but not enough for two, a cross connection is made between the turbine and one of the governors takes master control of its turbine, which delivers 60 cycle current on a fluctuating load to the Mt. Whitney system. The remaining turbine is then set in block load delivering its power into the 50 cycle system. By means of the cross connection between the units the master governor automatically sets the load limit on the block load unit so its guide vanes at once move to consume any water rejected by the master machine on load decrease or vice versa. Thus a constant flow equal to the maximum available water supply is made to do useful work instead of being allowed to run to waste over the spillway and the master unit always has available a water supply margin sufficient to take care of load fluctuations which always occur on a governing unit. The cross connection between the turbines makes it possible to use this margin quantity on the block load unit until needed for governing since a call for more water in the master unit will immediately act to decrease the consumption of the block load carrier by an equivalent amount. An adjustment is provided in the cross connection to correct for the variation of turbine gate discharge between the two units and to insure smooth operation in the water transfer. In addition to this cross-connection suitable means are provided to take care of seasonal variations in the supply of water.

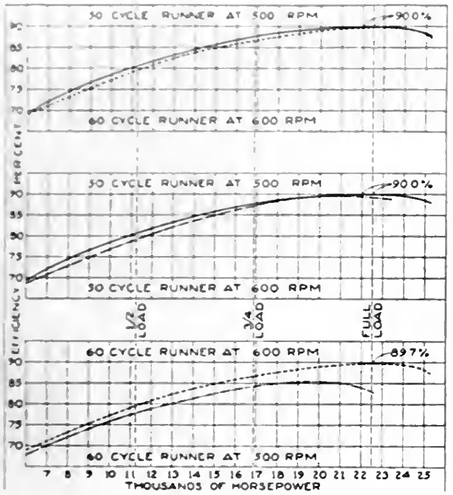

Fig. 6 Efficiency Curves of Turbines at Two Speeds and Two Frequencies

The units were very carefully tested for efficiency and to determine speed regulation, pressure rise and general conformance to the contract requirement.

Among other things these tests have shown that while there is very little difference in the efficiency of the 50-cycle runner operating at 500 r.p.m. or 600 r.p.m., there is a decided decrease of maximum output when the runner is not operating at its designed speed as illustrated in Fig. 3.

The loss in kilowatt-hours from this alone will make a change of runners advisable if sufficient water for the maximum capacity of the proper runner for as short a time as three weeks may be expected. On the other hand, if the 60-cycle demand is not likely to last that long it will not pay to make the change. This may be easily calculated by balancing the total additional kilowatt-hours produced against the output lost during a twenty-hour shut-down to change runners at the start and a second twenty-hour interval to change back again at the end of the run.

The curves show efficiencies of the 60-cycle, 600 r.p.m. runner operating at both normal speed and at 500 r.p.m. for 50-cycle generation. A marked difference in results is obtained. This is accounted for by the distortion in entrance and discharge angles as well as the increased distance between the ends of the guide vanes and the entrance of the runner.

The water is taken from the river by means of a concrete diversion dam of ogee form. After passing through an inclined grizzly, and two motor-operated head gates, it is carried by concrete flume for about one half mile to a double-compartment, reinforced-concrete sand-settling basin 400 ft. long by 60 ft. wide by 20 ft. deep. One compartment may be sluiced of sediment while the other is in use.

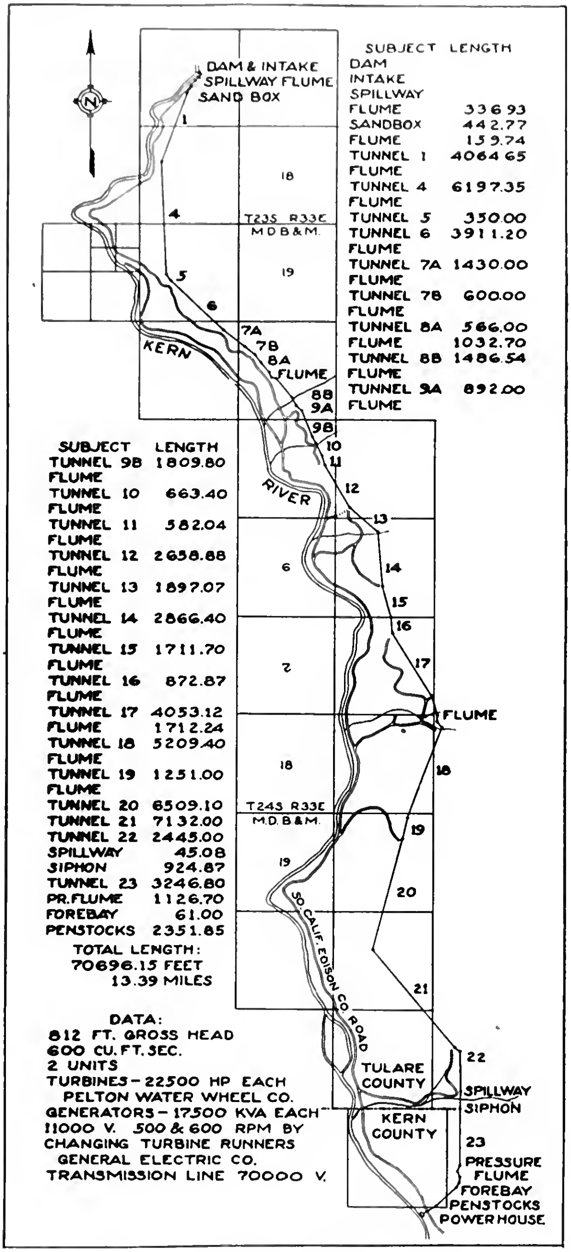

Fig. 7 Plan of Power-Water Supply System

From the sand-box to the surge-chamber, a distance of about 11$^1/_2$ miles, the conduit is mainly in tunnel, alternating with short stretches of concrete flume. The surge chamber is of reinforced concrete. A steel pipe 2520 ft. long, 84 in. in diameter at the surge-chamber, tapering to 60 in. at the power house, leads to each of the two turbines.

REDUCTION OF FUEL WASTES IN THE STEEL INDUSTRY

(*Continued from page 238*)

either by itself or in conjunction with by-product gas, and has been used for steam production either as an auxiliary fuel on blast-furnace boilers or by itself, and its use has been proposed to heat by-product ovens, thus releasing additional gas otherwise required for heating the ovens.

Heat Balance

Table 1 gives an example of the approximate heat balance of one ton of pig iron as used in the steel plant, using average figures, and based on an average coke consumption in the blast furnace of 2500 lb. of coke per ton of product.

TABLE I HEAT BALANCE FOR MANUFACTURE OF ONE TON OF PIG IRON

From the coke plant delivering one ton of coke there result the following fuel by-products for consumption in the steel plant after the heat and power requirements of the by-product plant have been met:

12 gal. tar at 162,500 B.t.u. per gal., B.t.u.	1,950,000	
30 lb. of coke breeze at 12,000 B.t.u. per lb., B.t.u.	360,000	
10,000 cu. ft. gas at 500 B.t.u. per cu. ft. (net value), B.t.u.	5,000,000	
Total per net ton coke		7,310,000
Heat available per ton pig iron	B.t.u.	B.t.u.
In tar from by-product plant	2,435,000	
In coke breeze from by-product plant	450,000	
In surplus gas	6,250,000	
Surplus from by-product plant		9,135,000
In blast furnace gas		19,635,000
Required for blast heating	5,000,000	
Required for blowing equipment	4,400,000	
Required for blast-furnace operation	1,000,000	
Required for total blast furnaces		10,400,000
Surplus from blast furnace plant		9,235,000
Total heat energy from by-products		18,370,000
Heat required for steel plant *Open hearth (pig iron to ingots)*		
Melting (approx.)	7,000,000	
Power, 25 kw. at 25,000 B.t.u. per kw-hr.	625,000	
Total heat consumption		7,625,000
Roughing Mill		
Heating (approx.)	2,000,000	
Power, 50 kw-hr.	1,250,000	
Total		3,250,000
Finishing Mill		
Heating (approx.)	4,000,000	
Power, 100 kw-hr.	2,500,000	
Total for finishing		6,500,000
Total heating requirements	13,000,000	
Total power requirements	4,375,000	
Total		17,375,000

Necessity of Heat Conservation

From Table 1 it will be seen that the total heat from the by-products of a ton of pig iron is more than sufficient to finish the average ton of steel, but upon inspection of the table it will be found that the heating requirements have not been met from tar and by-product gas, while the average power requirements are more than met from blast-furnace gas and coke breeze.

It therefore becomes very desirable to reduce the heating requirements for production of steel by using more efficient heating furnaces, and to conserve all possible heat by charging hot steel into the soaking pit and reheating furnaces, in order to reduce the quantity of fuel required for supplementary heating.

The production of gas at the by-product plant is practically uniform, while the consumption at the steel plant is variable and as a result the gas pressure at the steel plant (usually some distance away from the by-product plant) is variable. As gas holders of sufficient capacity to absorb the fluctuations have not been found advisable it becomes necessary to schedule the use of gas by consuming departments in order partially to equalize the consumption. In many cases it is advisable to use by-product gas under boilers (although it is more valuable for other purposes) in order to prevent or reduce its waste, as it is easier to change from gas to coal on boilers than to fire up producers.

One of the most important problems of the steel plant manager and engineer is so to regulate the production and consumption of the various fuels occurring as a by-product of steel-plant manufacture that the consumption of raw coal in producers or under boilers that would otherwise be sent to the by-product plant is a minimum, for the reason that the by-products from the coal, coked in the by-product plant, usually exceed any possible return as fuel.

COTTON-GINNING MACHINERY

(*Continued from page 236*)

largest size condenser. This is equivalent to a screen exposure when running, of from 2 sq. ft. down to 1 sq. ft. per saw per minute. The peripheral speed of the doffing rollers should be the same as that of the screen drum. From the condenser the lint cotton is delivered by the doffing rollers to the lint slide, thence into the press box.

The Cotton-Ginning Process

The seed cotton is brought to the cotton-gin plant in quantities of 1600 lb. when clean-picked cotton and of 2000 lb. to 2200 lb. when gathered or grabbed cotton. When ginned there will be a finished bale weighing about 500 lb., and 1050 lb. of cotton seed; the remainder is refuse, as trash, hulls, dirt and other foreign substances. The seed cotton is usually hauled in wagons, from which it is sucked off through a telescope by means of air-suction steel-plate centrifugal, fans operating at a blast-wheel peripheral speed of 11,000 to 13,000 ft. per min., and producing a vacuum of 14 to 16 in. of water. In the course of its travel the cotton is carried through a cleaner where it is agitated on a screen to remove the foreign substances; thence it passes to the elevating system where the air is separated from it, and is dropped into the gin feeders, where further cleaning is performed. The cotton is next delivered to the gin in such quantity as will not gorge the roll box but will be sufficient to insure a nice, moderately soft, pliable ginning roll. If the cotton is clean-picked it can be delivered direct to the ginning roll in a plain gin; but if gathered or grabbed it will contain hulls, etc., and should be delivered to a huller roll box.

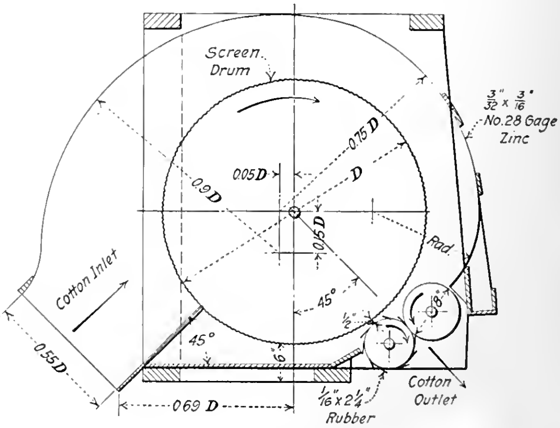

Fig. 15 Condenser

The seed fall from the roll box down into seed conveyor, from which they are delivered to the customer's seed box or into a seed storage house. The hulls, trash and foreign substances are conveyed outside of the gin house to the boiler room for fuel—that is, that part that is combustible—or hauled off to be used later as fertilizer. The motes are also conveyed out and in some instances used for low-grade fiber stock. The lint cotton passes from the gin to the lint flue and then to the condenser, where it is separated from the air and formed into a bat. It is then delivered into the press box for packing, wrapping and pressing, ready for the market, and after marketing is compressed and rewrapped before being export.

Textile Machinery to be Discussed at A.S.M.E Meeting

At the Atlanta Spring Meeting, May 8-11, of The American Society of Mechanical Engineers, the Textile Division will hold two joint sessions with the Machine Shop Division at which six papers on textile machinery will be presented. In addition to Mr. Gillespie's paper, printed above, the papers will deal with weaving, spinning, and carding machinery.

The Moody Ejector Turbine

Particulars of a Turbine for Low-Head Installations Which Delivers the Rated Horsepower at Maximum Efficiency When the Head is a Maximum, and also Maintains the Output When Head is Reduced at Flood Periods

By S. LOGAN KERR,[1] PHILADELPHIA, PA.

ONE of the greatest difficulties met in the operation of low-head hydroelectric power plants is the reduction of capacity during flood periods. It is usually impossible, owing to the nature of the surrounding country and the enormous quantity of water required, to provide storage reservoirs to such an extent that all excess water flowing during these flood periods can be entrained and used when the stream flow is below normal. Some regulation, of course, is effected in a few instances, but for the most part there is sufficient only to carry the plant over the daily peak.

Where the storage is thus limited, owing to the character of the country surrounding the plant, the flow of water during the flood season is much greater than is required by the turbines. This excess is therefore wasted over the dam, and in addition causes the tail water to rise in level.

Since the turbine operates upon the difference in level of the head and tail waters, should these levels vary the same amount, then this difference or head would be constant. Usually this is not the case, for with a given rise in level of the water going over the dam, the rise in the level of the tail water is greater, thus decreasing the net head. This effect is illustrated in Fig. 1. The head at low water is evidently much greater than at high water as reference to this sketch will show. The line intermediate between the two extremes shows the effect when the level of the head water is increased by a small amount. It is evident even in this case that the net head is decreased.

Since the horsepower of the turbine varies as the three-halves power of the head acting upon it, the output of the station is decreased in the same ratio, but as the operation is of necessity at constant speed, the efficiency may be less as well, depending upon the characteristics of the wheel, causing a still further decrease in capacity. Thus the resultant loss in power may be very great, depending upon the rate of off-flow of the tail water, which in turn is dependent upon the character of the stream bed below the dam.

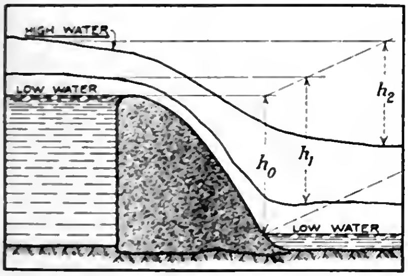

Fig. 1 Sketch Showing Decrease in Effective Head During Periods of High Water

As was stated above, in low-head plants where the quantity of water required to generate a given amount of power is large, the storage facilities are usually small. Therefore the turbine should be designed to give maximum efficiency at rated output when the head is a maximum, for at this time water is scarce and economical operation is imperative.

Due to their inherent characteristics, the high- or relatively high-speed wheels used in low-head work give as a rule a rather narrow operating range at maximum efficiency, and a small overload capacity beyond this point of maximum efficiency. To design a turbine, then, that would deliver the required output under a reduced head would be inadvisable, for this same turbine would not operate at best efficiency when delivering rated horsepower under the higher normal head resulting from low water.

This is illustrated in Fig. 2 where the turbine is designed to deliver 100 per cent of rating at 75 per cent of normal head. When this same turbine is operated under 100 per cent head, its capacity is increased to 140 per cent of rating; but as only 100 per cent is required, it is evident that the efficiency will be several per cent less than the maximum. This method of meeting the problem would be wasteful from the standpoint of economy of operation at maximum-head conditions.

Another method would be to install a number of additional units that could be placed in operation when the capacity of the plant was cut down at high water. Such a plant would require a much greater expenditure of money in the first cost, which could render a return on the investment for a short period only each year. This, then, is a possible solution, but the resultant fixed charges upon the plant would be so great, in many cases, as to make the cost of power prohibitive.

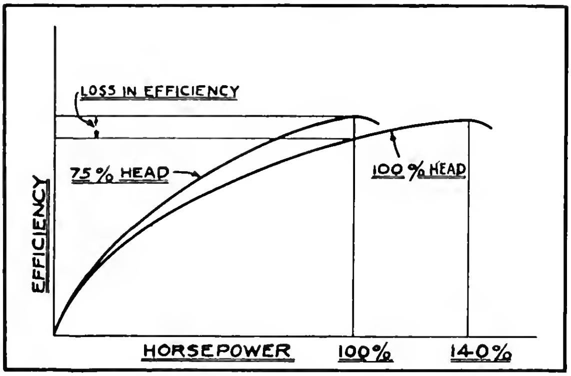

Fig. 2 Sketch Showing Disadvantage of Designing Turbine for Maximum Efficiency at the Minimum Head Conditions

There remains this problem: to design a turbine that will operate as economically as possible at times when the available supply of water is small, and yet develop normal rated power when the overabundance of water decreases the effective head.

The Moody Ejector Turbine

A turbine designed to meet these requirements has been developed by Mr. Lewis F. Moody. The apparatus consists of a turbine of the normal type designed to operate at maximum efficiency under the average head prevailing at times of low water, but at the top of the draft tube, just below the runner, an annular opening is made in the wall of the tube, the amount of this opening being controlled by a cylinder gate.

When the turbine is operating normally, this gate is closed and the contour of the draft tube is unchanged, as shown in Fig. 3. When the head falls off due to the rise of the tail water, this gate is opened slightly, allowing a jet of water at high velocity to enter the draft tube without first passing through the runner. This case is shown in Fig. 4. The action of the jet, expressed simply, is to "pull" more water through the runner and hence to increase the horsepower output of the turbine.

The jet actually creates an additional suction head that compensates for the loss in the difference in level between the head and tail water. So that the turbine is in reality operating under a

Extracts from a thesis submitted to the University of Pennsylvania for the degree of Bachelor of Science in Mechanical Engineering by the author in June, 1921. Awarded A.S.M.E. Junior Prize for the best paper during the year 1921. All papers are subject to revision.

head made up of two parts: first, the effective head measured as the difference in levels of the head and tail water (less, of course, the frictional head in the water passages); and second, the "suction head" produced by the action of the jet of water admitted below the runner. For this reason the device has been called an "ejector turbine."

Tests Made on the Turbine

The apparatus described above was set up and tested in the I. P. Morris Experimental Laboratory of the William Cramp & Sons Ship & Engine Building Company in Philadelphia. The turbine was equipped with guide vanes placed in the ejector. The function of these vanes, which will be called ejector vanes hereafter in order to avoid confusing them with the guide vanes and speed ring vanes of the turbine proper, is to give the water entering the ejector an initial whirl, so that there will be a minimum amount of interference with the water coming off the runner.

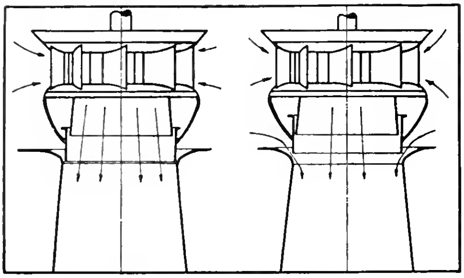

Fig.3 Fig.4

Figs. 3 and 4 Sketches Respectively Showing the Ejector Closed and Open

In the first series of tests (A1 to A6) model runner No. 55 was used. This runner (16 in. in diameter at the throat) is of the mixed-flow type and has a specific speed of 84.4 at best ϕ. The symbol ϕ represents the coefficient of peripheral velocity or the ratio of the linear velocity of a point on the runner to the theoretical spouting velocity of the water under the operating head. This ratio may be based on any one of several diameters, but in this article, the ϕ based on the diameter at the throat of the runner is meant. The values of specific speed (N_s) are all given in the English foot-pound system.

The first test (A1) was made at the maximum opening of the ejector (3.155 in.). The measurement of these openings was made by taking the average of a series of readings scaled off at various points around the ejector. A series of ϕ-Efficiency and ϕ-Horsepower curves under 1 ft. head and 1 ft. throat diameter was drawn for each test and the performance curves calculated from these. Description of the necessary calculations and of the method employed in testing are given in appendices to the complete paper.

A series of tests was made, each with a decreasing opening of the ejector until a point of 0.824 in. was reached. The next test (A6) was made with the ejector gate entirely closed.

However, this test did not give as good efficiency as was previously secured with the same runner and draft tube in another test. Upon investigation, it was found that the cylinder gate of the ejector did not seat properly upon the lower ring and that a small opening was left on one side of the turbine, thus admitting a small amount of water on about one-third of the periphery of the ejector. It is of interest to note that for any given gate opening of the turbine, although the efficiency was reduced about five per cent from that previously obtained, yet there resulted a slight increase in horsepower with even this small ejector opening.

In plotting performance curves of the values in test No. A6 the test efficiencies were stepped up to correspond with those obtained in previous tests. This is permissible, for in tests Nos. B6 and C2 made with runner No. 65, the ejector was calked tight to eliminate this difficulty and to correspond to the more perfect construction that would be found in large units built for commercial purposes. The results in these tests gave efficiencies that checked very closely with those obtained when the same runner was tested without the ejector installed.

Another series of tests was made using runner No. 65 in place of runner No. 55. This runner (16.25 in. in diameter at the throat) is of the "diagonal-flow" type and has a specific speed of approximately 100. This series of tests (B1 to B6) was run with varying openings of the ejector, but the angle of the ejector vanes was changed to conform with the variation in the theoretical value of the whirling component of the water leaving the runner with the increase in specific speed.

When this series had been run, it was thought advisable to test runner No. 65 with the ejector vanes removed in order to study the effect of the ejector water without this initial whirl.

Investigation of the Influence of Ejector upon the Flow in Draft Tube

It was desired as well to see the effect that the water injected into the draft tube through the ejector would have upon the normal flow of water coming off the runner. In order to measure the velocity of water in the draft tube it is necessary to know the direction that it takes, since the flow is not the same as in a pipe line or canal, but moves with a whirling motion and follows a path similar to a helix in form. The steepness of this helix depends upon a great number of conditions, principal among which are the type of runner, the speed, and the load under which the turbine is operating.

An instrument was developed by the writer with the coöperation of the staff in charge of experimental work of the I. P. Morris Department especially for this test to measure the velocity and direction of flow in the draft tube. The apparatus, because of its form and the use for which it was designed, has been called a "pitot velometer."

The pitot velometer consists of a double pitot tube similar to the "Pitometer" with symmetrical openings 180 deg. apart. The head was arranged so the maximum dimension would pass through a hole the size of the outside diameter of standard $^3/_8$-in. pipe. The whole head, rod, and end connections are free to rotate and move in and out from the center line of the draft tube. A pointer is fixed on the outer end of the instrument, and a dial hung on a ball bearing and weighted to keep the zero of the scale vertical showed the position of the center line of the openings in the head.

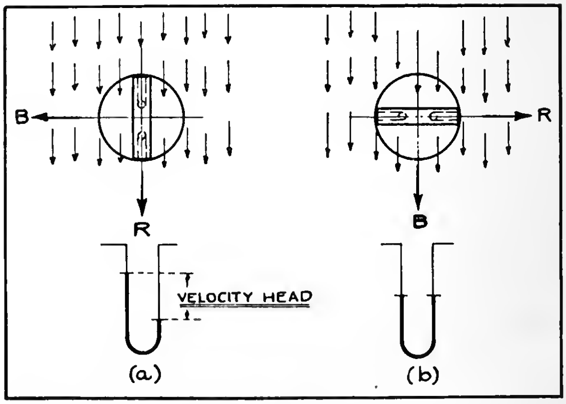

Fig. 5 Positions of Pitot Velometer (a) when Reading Velocity and (b) when Reading Deviation from Vertical
(R indicates red pointer; B, black pointer.)

These two opeinings were attached to the legs of a differential gage filled with mercury and when the head was turned to a position so that the two openings were in a line with the flow of the water, the velocity head was indicated on the gage. When the rod was rotated through 90 deg., the center line through the openings was perpendicular to the flow, and the two legs of the gage stood at the same level. It was found that the apparatus was very much more sensitive in this position than with the openings in line with the flow, and that the angle of deviation from the vertical could be more accurately read.

For this reason two pointers were attached to the rod; one painted black was set at right angles to the line through the center

of the openings, and the other painted red set parallel with this line.

In taking a reading, the rod was set at the desired point on the diameter of the draft tube and rotated until the two legs of the differential gage stood equal, this position is shown in Fig. 5 (*b*). The reading of the deviation was recorded as shown by the black pointer. The red pointer was then brought to this point, automatically placing the openings in line with the flow and the velocity read by the difference in levels of the mercury columns. This

position is shown in Fig. 5 (*a*). The scale of the dial was graduated in degrees and half-degrees. It was possible to measure the deviation of this velocity from the vertical accurately to within a single degree.

The scale of the mercury gage was graduated to read zero when the two legs were equal; below this line the scale was laid off in inches of mercury. Above the zero line the scale was so arranged to give the velocity directly in feet per second. The pitot velometer was located approximately 24 inches below the horizontal center line of the turbine.

The diameter of the draft tube at the point where the instrument was installed was $19\frac{3}{4}$ in., but as the flow was investigated on one side only of the tube, the horizontal motion of the head was one-half of the diameter or $9\frac{7}{8}$ in.

Readings were taken at each even inch from the vertical center line up to and including a point at a radius of 9 in., thus making a total of ten readings for one complete traverse.

It was thought best, due to the time required (seven to ten

minutes) for one complete traverse of the draft tube, with ten readings each of velocity and angle of deviation from the vertical, to take traverses only at points within the possible operating range of the turbine, or of a turbine of this type installed in a power plant.

Since the limits of maximum and minimum ϕ for this range could easily be determined, three traverses were made for each gate opening at points within these limits. A large number of traverses were made, two examples of which are shown in Figs. 14 and 15.

Two tests were made, the first (C1) was run with the ejector

open about one and one-half inches, the second (C2) was made with the ejector closed and caulked, to have, as a basis of comparison, the flow of water coming from the runner uninfluenced by the ejector water.

Results of Tests

In order to show the increase in horsepower obtained by use of the ejector over that normally delivered by the turbine, a series of performance curves was drawn with efficiencies as ordinates and horsepower under 1 ft. head reduced to 1 ft. throat diameter as abscissae. These curves were drawn for each of the tests in the first and second series. The envelope of these curves was then drawn in and is taken as the performance of the turbine and ejector combined.

It may be seen from Figs. 6 and 9 that a considerable increase over the rated output is obtained by the use of the ejector. This increase is 36.7 per cent based on rating of 0.300 hp. under 1 ft. head and 1 ft. throat diameter for runner No. 55 and 30.0 per cent for runner No. 65 equipped with vanes in the ejector. Based on the maximum power obtainable these values are 34.5 per cent for runner No. 55 and 17.0 per cent for runner No. 65.

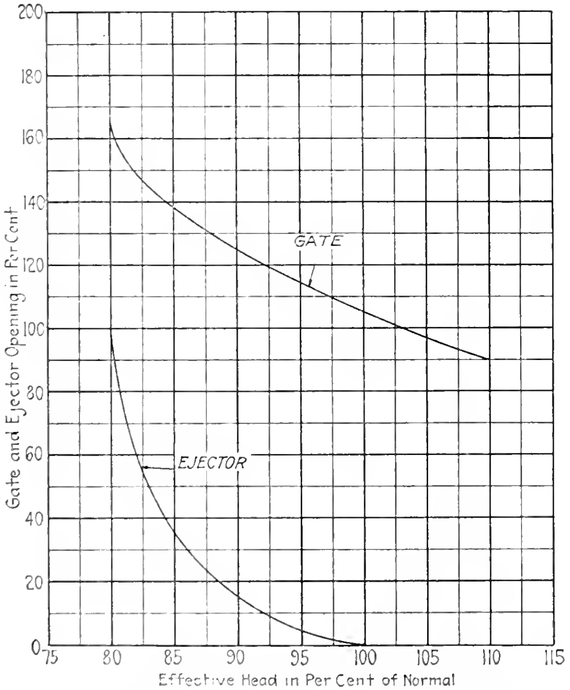

Fig. 12 Constant-Horsepower Curves, Runner No. 55

A second set of curves (Figs. 7 and 10) was plotted showing the performance of the turbine and ejector under varying heads, each curve consisting of two parts, the normal performance curve and the envelope of the several ejector performance curves. Curves are plotted for 70, 80, 90, 100 and 110 per cent of normal head, the latter being taken as 1 ft. to have a standard for a basis of comparison. Along with these curves have also been plotted curves of horsepower against quantity.

Guide vane and ejector openings have also been plotted against horsepower and appear as Figs. 8 and 11. In all of these results there has been no allowance made for the increased frictional losses in the water passages leading up to the turbine, since the model tested was of the open-flume type. Therefore the losses resulting from the increase in quantity flowing must be calculated for each individual case where the ejector is to be applied. It should be noted that the results include some of the losses, namely, the losses within the turbine and the losses in the draft tube, but not the losses that would occur in the penstock or the casing. It is probable that these will not be excessively large, since low-head installations have relatively short penstocks which are usually integral with the dam.

It may be noted that with runner No. 55, normal rated horsepower can be maintained under 80 per cent head and under 83 per cent head with runner No. 65, when both are equipped with guide vanes in the ejector.

From the curves of horsepower, gate and ejector opening, another series of curves was obtained (Figs. 12 and 13). These might be called very appropriately "Constant-Horsepower Curves." The ordinates are per cent ejector or gate opening and the abscissae are per cent normal head. If, therefore, the per cent of normal head under which the turbine is operating is known, by finding the points where the gate and ejector opening curves cross this line, the proper setting of the turbine and ejector gates that will maintain rated capacity may be read. These curves are plotted for each of the two main series of tests.

In Fig. 10 (curves of horsepower and efficiency under varying heads for runner No. 65) a set of small curves, one for each 10 per cent of normal head from 70 to 110 per cent are drawn for comparison with the other performance curves. These are the results of test No. C1 (runner No. 65 with ejector vanes removed), and it may be seen that there is a slight numerical increase in horsepower over that obtained with the vanes in place, but judging from the position of these curves with relation to the others and to the shape of the envelope of the curves of varying ejector openings, it is reasonable to suppose that the maximum increase obtainable with the ejector vanes removed is much greater than the actual numerical difference would indicate. It would seem that the turbine was operating on the drowned part of the envelope.

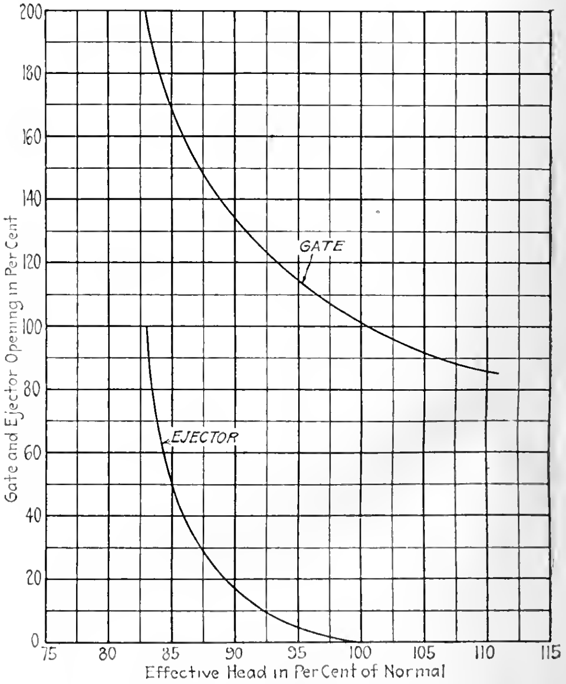

Fig. 13 Constant-Horsepower Curves, Runner No. 65

The explanation of this is probably that the increase in area of the opening with the vanes removed was greater than that required to secure maximum horsepower, and had the effect of drowning the turbine. If the opening had been smaller, the actual maximum horsepower obtainable with the vanes removed would have been secured.

In all the foregoing tests the turbine was equipped with the Moody spreading draft tube, and it is reasonable to suppose that the results are considerably better than could have been obtained with a straight or curved tube of another form. This statement is borne out by recent tests comparing the performance of various draft tubes.

Conclusions Regarding Flow in the Draft Tube

When the turbine is operating at normal ϕ, the whirling component of the water coming off the runner is in the direction of rotation of the turbine. In all readings of the deviation of this velocity from the vertical, this direction is taken as positive.

From curves of traverses made both with and without the ejector open, it has been found that if the turbine is overgated this whirl may become negative, due to the excess of water passing through the runner. At overload the runner is not moving in the same relation to the water as at normal operation, and the whirl under these conditions may become negative at all but very large values of ϕ. When the turbine is operating at high values of ϕ, the whirl is positive, or nearly so, even though the turbine is overgated.

From comparisons of traverses made with and without the ejector open, the following general conclusions may be drawn (see Figs. 14 and 15):

1 The characteristic form of the curve of the angle of deviation from the vertical was not influenced by the water from the ejector.

2 The velocity of the water at the outer portion of the draft tube was increased by the action of the ejector water over values obtained without the ejector open.

3 The ejector had little or no effect upon the flow of water coming from the runner up to and including a point about $6\frac{1}{2}$ in. from the center line of the draft tube, or in other words, the inner two-thirds of the draft tube was not affected by the ejector.

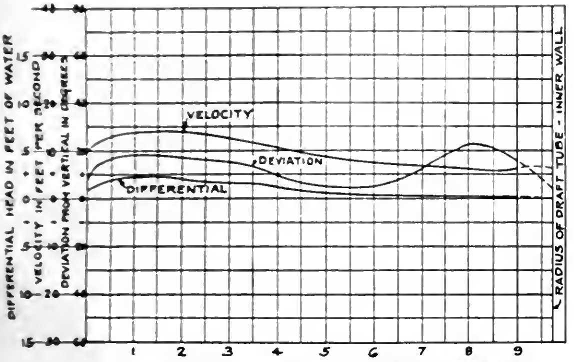

Fig. 14 Flow in Draft Tube, Ejector Closed; Gate Opening 40 Per Cent; $\phi = 1.262$; Runner No. 65

4 The action of the runner influenced the direction of the flow of water issuing from the ejector, and not vice versa.

By referring to the curves plotted from results of these traverses, it may be seen that the angle of whirl is very nearly the same regardless of whether the ejector is open or not, but that the velocity of the water in the outer third of the draft tube is increased considerably over that with the ejector closed.

Summary

As was stated in the introduction, the need for the ejector type of turbine is felt only in low-head installations where the reduction in head due to flood periods reduces the capacity of the plant to an appreciable extent.

It is obvious that instead of wasting the excess water that would ordinarily pass over the dam during these periods, the ejector uses this same water to counteract the reduction of the effective head and to maintain the rated output of the plant.

While it is imperative that the turbine operate at maximum efficiency when the head is a maximum and water is scarce, it is also true that economical operation is secondary to the maintenance of rated output when there is so great an overabundance of water that the capacity is reduced.

The Moody ejector turbine meets these requirements, for under design conditions it operates as a normal turbine delivering rated horsepower at maximum efficiency; but when the head is reduced at flood periods, the cylinder gate on the ejector is opened and the output is maintained.

This turbine also finds its application, where stream flow and storage conditions permit, in carrying peak loads. At this time the ejector would have the effect as illustrated in the curves of horsepower and efficiency under constant head (Figs. 6 and 9). The maximum possible horsepower that can be obtained is that indicated by the envelope of the several ejector curves. The turbines would therefore be designed to deliver rated power for the average load and rely upon the ejector to carry the peaks. The application of the ejector to these conditions could only be effected where the peak loads could be accurately estimated in advance.

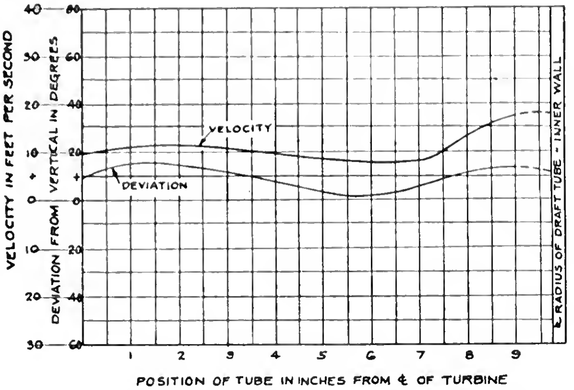

Fig. 15 Flow in Draft Tube, Ejector Open 1.54 in.; Gate Opening 40 Per Cent; $\phi = 1.306$; Runner No. 65

In conclusion, the Moody ejector turbine finds its principal application in low-head installations where the effective head is reduced by flood conditions and great fluctuations occur in the stream flow between high and low water.

Public Conference on Business Training of the Engineer

The United States Commissioner of Education is calling a second public conference on commercial engineering on behalf of a committee on commercial engineering appointed by him to investigate business training of engineers and engineering training for students of business.
